To our students,
whose enthusiasm and curiosity
have often inspired us,
and whose questions and suggestions
have sometimes taught us.

BRIEF CONTENTS

Preface xx

- l Introduction: Matter and Measurement 2
- 2 Atoms, Molecules, and Ions 40
- 3 Chemical Reactions and Reaction Stoichiometry 80
- 4 Reactions in Aqueous Solution 122
- 5 Thermochemistry 164
- 6 Electronic Structure of Atoms 212
- 7 Periodic Properties of the Elements 256
- 8 Basic Concepts of Chemical Bonding 298
- 9 Molecular Geometry and Bonding Theories 342
- 10 Gases 398
- ll Liquids and Intermolecular Forces 442
- 12 Solids and Modern Materials 480
- 13 Properties of Solutions 530
- 14 Chemical Kinetics 574
- 15 Chemical Equilibrium 628
- 16 Acid-Base Equilibria 670
- 17 Additional Aspects of Aqueous Equilibria 724
- 18 Chemistry of the Environment 774
- 19 Chemical Thermodynamics 812
- 20 Electrochemistry 856
- 21 Nuclear Chemistry 908
- 22 Chemistry of the Nonmetals 952
- 23 Transition Metals and Coordination Chemistry 996
- 24 The Chemistry of Life: Organic and Biological Chemistry 1040

APPENDICES

- A Mathematical Operations 1092
- B Properties of Water 1099
- C Thermodynamic Quantities for Selected Substances at 298.15 K (25 °C) 1100
- D Aqueous Equilibrium Constants 1103
- E Standard Reduction Potentials at 25 °C 1105

Answers to Selected Exercises A-1

CONTENTS

Preface xx

Introduction: Matter and Measurement 2

1.1 The Study of Chemistry 2

The Atomic and Molecular Person

The Atomic and Molecular Perspective of Chemistry 4 Why Study Chemistry? 5

1.2 Classifications of Matter 6
States of Matter 7 Pure Substances 7

States of Matter 7 Pure Substances 7
Elements 7 Compounds 8 Mixtures 10

1.3 Properties of Matter 11
Physical and Chemical Changes 12
Separation of Mixtures 13

1.4 Units of Measurement 14
SI Units 15 Length and Mass 17
Temperature 17 Derived SI Units 19
Volume 19 Density 19

1.5 Uncertainty in Measurement 22
Precision and Accuracy 22 Significant
Figures 22 Significant Figures in
Calculations 22

1.6 Dimensional Analysis 27
Using Two or More Conversion Factors 28
Conversions Involving Volume 29
Chapter Summary and Key Terms 32
Learning Outcomes 32
Key Equations 32 Exercises 32 Additional
Exercises 37

- ▲ Chemistry Put to Work Chemistry and the Chemical Industry 6
- ▲ A Closer Look The Scientific Method 14
- ▲ Chemistry Put to Work Chemistry in the News 20
- ▲ Strategies in Chemistry Estimating Answers 28
- ▲ Strategies in Chemistry The Importance of Practice 31
- ▲ Strategies in Chemistry The Features of This Book 32

2 Atoms, Molecules, and Ions 40

- 2.1 The Atomic Theory of Matter 42
- 2.2 The Discovery of Atomic Structure 43
 Cathode Rays and Electrons 43
 Radioactivity 45 The Nuclear Model of the
 Atom 46
- 2.3 The Modern View of Atomic Structure 47
 Atomic Numbers, Mass Numbers, and
 Isotopes 49
- 2.4 Atomic Weights 50

 The Atomic Mass Scale 50 Atomic Weight 51
- 2.5 The Periodic Table 52
- 2.6 Molecules and Molecular Compounds 56

Molecules and Chemical Formulas 56 Molecular and Empirical Formulas 56 Picturing Molecules 57

- 2.7 Ions and Ionic Compounds 58
 Predicting Ionic Charges 59 Ionic
 Compounds 60
- Naming Inorganic Compounds 62
 Names and Formulas of Ionic Compounds 62
 Names and Formulas of Acids 67
 Names and Formulas of Binary Molecular Compounds 68
- 2.9 Some Simple Organic Compounds 69
 Alkanes 69 Some Derivatives of Alkanes 70
 Chapter Summary and Key Terms 72
 Learning Outcomes 72 Key
 Equations 73 Exercises 73
 Additional Exercises 78
 - ▲ A Closer Look Basic Forces 49
 - ▲ A Closer Look The Mass Spectrometer 52
 - ▲ A Closer Look What Are Coins Made Of? 54
 - ▲ Chemistry and Life Elements Required by Living Organisms 61
 - ▲ Strategies in Chemistry How to Take a Test 71

Ghemical Reactions and Reaction Stoichiometry 80

3.1 Chemical Equations 82 Balancing Equations 82 Indicating the States of Reactants and Products 85

- 3.2 Simple Patterns of Chemical Reactivity 86
 Combination and Decomposition
 Reactions 86 Combustion Reactions 89
- 3.3 Formula Weights 89

 Formula and Molecular Weights 90

 Percentage Composition from Chemical
 Formulas 91
- 3.4 Avogadro's Number and the Mole 91

 Molar Mass 93 Interconverting Masses
 and Moles 95 Interconverting Masses and
 Numbers of Particles 96
- 3.5 Empirical Formulas from Analyses 98

 Molecular Formulas from Empirical
 Formulas 100 Combustion Analysis 101
- 3.6 Quantitative Information from Balanced Equations 103
- 3.7 Limiting Reactants 106

 Theoretical and Percent Yields 109

 Chapter Summary and Key Terms 111

 Learning Outcomes 111 Key Equations 112

 Exercises 112 Additional Exercises 118

 Integrative Exercises 120 Design an

 Experiment 120
 - ▲ Strategies in Chemistry Problem Solving 92
 - **▲** Chemistry and Life Glucose Monitoring 95
 - ▲ Strategies in Chemistry Design an Experiment 110

4 Reactions in Aqueous Solution 122

4.1 General Properties of Aqueous Solutions **124**

Electrolytes and Nonelectrolytes 124 How Compounds Dissolve in Water 125 Strong and Weak Electrolytes 126

4.2 Precipitation Reactions 128

Solubility Guidelines for Ionic Compounds 129 Exchange (Metathesis) Reactions 130 Ionic Equations and Spectator Ions 131

4.3 Acids, Bases, and Neutralization Reactions 132

Acids 132 Bases 133 Strong and Weak Acids and Bases 133 Identifying Strong and Weak Electrolytes 135 Neutralization Reactions and Salts 135 Neutralization Reactions with Gas Formation 138

- 4.4 Oxidation-Reduction Reactions 138
 Oxidation and Reduction 138 Oxidation
 Numbers 140 Oxidation of Metals by Acids
 and Salts 142 The Activity Series 143
- 4.5 Concentrations of Solutions 146
 Molarity 146 Expressing the Concentration of an Electrolyte 147 Interconverting Molarity, Moles, and Volume 148 Dilution 149
- 4.6 Solution Stoichiometry and Chemical Analysis 151

Titrations 152

Chapter Summary and Key Terms 155 Learning Outcomes 156 Key Equations 156 Exercises 156 Additional Exercises 161 Integrative Exercises 161 Design an Experiment 163

- ▲ Chemistry Put to Work Antacids 139
- ▲ Strategies in Chemistry Analyzing Chemical Reactions 146

5 Thermochemistry 164

5.1 Energy 166

Kinetic Energy and Potential Energy 166 Units of Energy 168 System and Surroundings 169 Transferring Energy: Work and Heat 169

5.2 The First Law of Thermodynamics 170

Internal Energy 171 Relating ΔE to Heat and Work 172 Endothermic and Exothermic Processes 173 State Functions 174

5.3 Enthalpy 175

Pressure–Volume Work 175 Enthalpy Change 177

5.4 Enthalpies of Reaction 179

5.5 Calorimetry 181

Heat Capacity and Specific Heat 181 Constant-Pressure Calorimetry 183 Bomb Calorimetry (Constant-Volume Calorimetry) 185

5.6 Hess's Law 187

5.7 Enthalpies of Formation 189

Using Enthalpies of Formation to Calculate Enthalpies of Reaction 192

5.8 Foods and Fuels 194

Foods 194 Fuels 197 Other Energy Sources 198

Chapter Summary and Key Terms 200 Learning Outcomes 201 Key Equations 202 Exercises 202 Additional Exercises 209 Integrative Exercises 210 Design an Experiment 211

- ▲ A Closer Look Energy, Enthalpy, and *P–V*Work 178
- ▲ Strategies in Chemistry Using Enthalpy as a Guide 181
- ▲ Chemistry and Life The Regulation of Body Temperature 186
- ▲ Chemistry Put to Work The Scientific and Political Challenges of Biofuels 198

6 Electronic Structure of Atoms 212

- 6.1 The Wave Nature of Light 214
- 6.2 Quantized Energy and Photons 216

 Hot Objects and the Quantization of Energy 216

 The Photoelectric Effect and Photons 217
- 6.3 Line Spectra and the Bohr Model 219
 Line Spectra 219 Bohr's Model 220
 The Energy States of the Hydrogen Atom 221
 Limitations of the Bohr Model 223
- 6.4 The Wave Behavior of Matter 223
 The Uncertainty Principle 225
- 6.5 Quantum Mechanics and Atomic Orbitals 226

Orbitals and Ouantum Numbers 228

6.6 Representations of Orbitals 230 The s Orbitals 230 The p Orbitals 233 The d and f Orbitals 233

and the Pauli Exclusion Principle 235

6.7 Many-Electron Atoms 234
Orbitals and Their Energies 234 Electron Spin

6.8 Electron Configurations 237

Hund's Rule 237 Condensed Electron Configurations 239 Transition Metals 240 The Lanthanides and Actinides 240

6.9 Electron Configurations and the Periodic Table 241

Anomalous Electron Configurations 245
Chapter Summary and Key Terms 246
Learning Outcomes 247 Key Equations 247
Exercises 248 Additional Exercises 252
Integrative Exercises 255 Design an
Experiment 255

- ▲ A Closer Look Measurement and the Uncertainty Principle 225
- ▲ A Closer Look Thought Experiments and Schrödinger's Cat 227
- ▲ A Closer Look Probability Density and Radial Probability Functions 232
- ▲ Chemistry and Life Nuclear Spin and Magnetic Resonance Imaging 236

Periodic Properties of the Elements 256

- 7.1 Development of the Periodic Table 258
- 7.2 Effective Nuclear Charge 259
- 7.3 Sizes of Atoms and Ions 262Periodic Trends in Atomic Radii 264 PeriodicTrends in Ionic Radii 265
- 7.4 Ionization Energy 268

 Variations in Successive Ionization
 Energies 268 Periodic Trends in First
 Ionization Energies 268 Electron
 Configurations of Ions 271
- 7.5 Electron Affinity 272
- 7.6 Metals, Nonmetals, and Metalloids 273

Metals 274 Nonmetals 276 Metalloids 277

7.7 Trends for Group 1A and Group 2A Metals 278

Group 1A: The Alkali Metals 278 Group 2A: The Alkaline Earth Metals 281

7.8 Trends for Selected Nonmetals 282

Hydrogen 282 Group 6A: The Oxygen Group 283 Group 7A: The Halogens 284 Group 8A: The Noble Gases 286

Chapter Summary and Key Terms 288
Learning Outcomes 289 Key Equations 289
Exercises 289 Additional Exercises 294
Integrative Exercises 296 Design an
Experiment 297

- ▲ A Closer Look Effective Nuclear Charge 261
- ▲ Chemistry Put to Work Ionic Size and Lithium-Ion Batteries 267
- ▲ Chemistry and Life The Improbable Development of Lithium Drugs 281

Basic Concepts of Chemical Bonding 298

- 8.1 Lewis Symbols and the Octet Rule 300
 The Octet Rule 300
- 8.2 Ionic Bonding 301

Energetics of Ionic Bond Formation 302 Electron Configurations of Ions of the s- and p-Block Elements 305 Transition Metal Ions 306

8.3 Covalent Bonding 306

Lewis Structures 307 Multiple Bonds 308

- 8.4 Bond Polarity and Electronegativity 309
 Electronegativity 309 Electronegativity and
 Bond Polarity 310 Dipole Moments 311
 Differentiating Ionic and Covalent Bonding 314
- 8.5 Drawing Lewis Structures 315
 Formal Charge and Alternative Lewis
 Structures 317
- 8.6 Resonance Structures 320
 Resonance in Benzene 322
- 8.7 Exceptions to the Octet Rule 322
 Odd Number of Electrons 323 Less Than an
 Octet of Valence Electrons 323 More Than an
 Octet of Valence Electrons 324
- 8.8 Strengths and Lengths of Covalent Bonds 325

Bond Enthalpies and the Enthalpies of Reactions 327 Bond Enthalpy and Bond Length 329

Chapter Summary and Key Terms 332
Learning Outcomes 333 Key Equations 333
Exercises 333 Additional Exercises 338
Integrative Exercises 340 Design an
Experiment 341

- ▲ A Closer Look Calculation of Lattice Energies: The Born–Haber Cycle 304
- ▲ A Closer Look Oxidation Numbers, Formal Charges, and Actual Partial Charges 319
- ▲ Chemistry Put to Work Explosives and Alfred Nobel 330

9 Molecular Geometry and Bonding Theories 342

- 9.1 Molecular Shapes 344
- 9.2 The VSEPR Model 347

Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles 351 Molecules with Expanded Valence Shells 352 Shapes of Larger Molecules 355

- 9.3 Molecular Shape and Molecular Polarity 356
- 9.4 Covalent Bonding and Orbital Overlap 358
- 9.5 Hybrid Orbitals 359
 sp Hybrid Orbitals 360 sp² and sp³ Hybrid
 Orbitals 361 Hypervalent Molecules 362
 Hybrid Orbital Summary 364
- 9.6 Multiple Bonds 365

Resonance Structures, Delocalization, and π Bonding 368 General Conclusions about σ and π Bonding 372

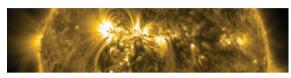

9.7 Molecular Orbitals 373

Molecular Orbitals of the Hydrogen Molecule 373 Bond Order 375

9.8 Period 2 Diatomic Molecules 376

Molecular Orbitals for Li₂ and Be₂ 377 Molecular Orbitals from 2p Atomic Orbitals 377 Electron Configurations for B₂ through Ne₂ 381 Electron Configurations and Molecular Properties 383 Heteronuclear Diatomic Molecules 384 Chapter Summary and Key Terms 386 Learning Outcomes 387 Key Equations 388 Exercises 388 Additional Exercises 393 Integrative Exercises 396 Design an Experiment 397

- ▲ Chemistry and Life The Chemistry of Vision 372
- ▲ A Closer Look Phases in Atomic and Molecular Orbitals 379
- ▲ Chemistry Put to Work Orbitals and Energy 385

Gases 398

- 10.1 Characteristics of Gases 400
- 10.2 Pressure 401

Atmospheric Pressure and the Barometer 401

10.3 The Gas Laws 404

The Pressure-Volume Relationship: Boyle's Law 404 The Temperature-Volume Relationship: Charles's Law 406 The Quantity-Volume Relationship: Avogadro's Law 406

- 10.4 The Ideal-Gas Equation 408
 Relating the Ideal-Gas Equation and the Gas
- Laws 410

 10.5 Further Applications of the Ideal-Gas
 Equation 412

Gas Densities and Molar Mass 413 Volumes of Gases in Chemical Reactions 414

10.6 Gas Mixtures and Partial Pressures 415

Partial Pressures and Mole Fractions 417

10.7 The Kinetic-Molecular Theory of Gases 418

Distributions of Molecular Speed 419 Application of Kinetic-Molecular Theory to the Gas Laws 420

- 10.8 Molecular Effusion and Diffusion 421
 Graham's Law of Effusion 423 Diffusion and
 Mean Free Path 424
- 10.9 Real Gases: Deviations from Ideal Behavior 426

The van der Waals Equation 428

Chapter Summary and Key Terms 431 Learning Outcomes 431 Key Equations 432 Exercises **432** Additional Exercises **438** Integrative Exercises **440** Design an Experiment **441**

- ▲ Strategies in Chemistry Calculations Involving Many Variables 410
- ▲ A Closer Look The Ideal-Gas Equation 421
- ▲ Chemistry Put to Work Gas Separations 425

11 Liquids and Intermolecular Forces 442

- 11.1 A Molecular Comparison of Gases, Liquids, and Solids 444
- 11.2 Intermolecular Forces 446
 Dispersion Forces 447 Dipole-Dipole
 Forces 448 Hydrogen Bonding 449
 Ion-Dipole Forces 452 Comparing

Intermolecular Forces 452

- 11.3 Select Properties of Liquids 455
 Viscosity 455 Surface Tension 456 Capillary
 Action 456
- 11.4 Phase Changes 457

 Energy Changes Accompanying Phase
 Changes 457 Heating Curves 459 Critical
 Temperature and Pressure 460
- 11.5 Vapor Pressure 461
 Volatility, Vapor Pressure, and

Temperature 462 Vapor Pressure and Boiling Point 463

11.6 Phase Diagrams 464

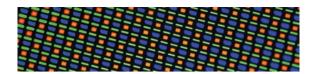

The Phase Diagrams of H₂O and CO₂ 465

11.7 Liquid Crystals 467

Types of Liquid Crystals 467

Chapter Summary and Key Terms 470 Learning Outcomes 471 Exercises 471 Additional Exercises 477 Integrative Exercises 478 Design an Experiment 479

- ▲ Chemistry Put to Work Ionic Liquids 454
- ▲ A Closer Look The Clausius–Clapeyron Equation 463

12 Solids and Modern Materials 480

- 12.1 Classification of Solids 480
- 12.2 Structures of Solids 482
 Crystalline and Amorphous Solids 482 Unit
 Cells and Crystal Lattices 483 Filling the Unit
 Cell 485
- 12.3 Metallic Solids 486

 The Structures of Metallic Solids 487 Close Packing 488 Alloys 491
- 12.4 Metallic Bonding 494

 Electron-Sea Model 494 Molecular-Orbital
 Model 495
- 12.5 Ionic Solids 498
 Structures of Ionic Solids 498
- 12.6 Molecular Solids 502
- 12.7 Covalent-Network Solids 503
 Semiconductors 504 Semiconductor
 Doping 506
- 12.8 Polymers 507

 Making Polymers 509 Structure and Physical Properties of Polymers 511
- 12.9 Nanomaterials 514
 Semiconductors on the Nanoscale 514 Metals on the Nanoscale 515 Carbons on the Nanoscale 516

Chapter Summary and Key Terms 519
Learning Outcomes 520 Key Equation 520
Exercises 521 Additional Exercises 527
Integrative Exercises 528 Design an
Experiment 529

- ▲ A Closer Look X-ray Diffraction 486
- ▲ Chemistry Put to Work Alloys of Gold 494
- ▲ Chemistry Put to Work Solid-State Lighting 508
- ▲ Chemistry Put to Work Recycling Plastics 511

Properties of Solutions 530

13.1 The Solution Process 530

The Natural Tendency toward Mixing 532
The Effect of Intermolecular Forces on Solution
Formation 532 Energetics of Solution
Formation 533 Solution Formation and
Chemical Reactions 535

- 13.2 Saturated Solutions and Solubility 536
- 13.3 Factors Affecting Solubility 538
 Solute–Solvent Interactions 538 Pressure
 Effects 541 Temperature Effects 543
- 13.4 Expressing Solution Concentration 544

 Mass Percentage, ppm, and ppb 544 Mole
 Fraction, Molarity, and Molality 545

 Converting Concentration Units 547
- 13.5 Colligative Properties 548

Vapor-Pressure Lowering 548 Boiling-Point Elevation 551 Freezing-Point Depression 552 Osmosis 554 Determination of Molar Mass from Colligative Properties 557

13.6 Colloids 559

Hydrophilic and Hydrophobic Colloids 560 Colloidal Motion in Liquids 562

Chapter Summary and Key Terms 564
Learning Outcomes 565 Key Equations 565
Exercises 566 Additional Exercises 571
Integrative Exercises 572 Design an
Experiment 573

- ▲ Chemistry and Life Fat-Soluble and Water-Soluble Vitamins 539
- ▲ Chemistry and Life Blood Gases and Deep-Sea Diving 544
- ▲ A Closer Look Ideal Solutions with Two or More Volatile Components 550
- ▲ A Closer Look The Van't Hoff Factor 558
- ▲ Chemistry and Life Sickle-Cell Anemia 562

14 Chemical Kinetics 574

- 14.1 Factors that Affect Reaction Rates 576
- 14.2 Reaction Rates 577

Change of Rate with Time 579 Instantaneous Rate 579 Reaction Rates and Stoichiometry 580

14.3 Concentration and Rate Laws 581

Reaction Orders: The Exponents in the Rate Law 584 Magnitudes and Units of Rate Constants 585 Using Initial Rates to Determine Rate Laws 586

14.4 The Change of Concentration with Time 587

First-Order Reactions 587 Second-Order Reactions 589 Zero-Order Reactions 591 Half-Life 591

14.5 Temperature and Rate 593

The Collision Model 593 The Orientation Factor 594 Activation Energy 594 The Arrhenius Equation 596 Determining the Activation Energy 597

14.6 Reaction Mechanisms 599

Elementary Reactions 599 Multistep Mechanisms 600 Rate Laws for Elementary Reactions 601 The Rate-Determining Step for a Multistep Mechanism 602 Mechanisms with a Slow Initial Step 603 Mechanisms with a Fast Initial Step 604

14.7 Catalysis **606**

Homogeneous Catalysis 607 Heterogeneous Catalysis 608 Enzymes 609

Chapter Summary and Key Terms 614 Learning Outcomes 614 Key Equations 615 Exercises 615 Additional Exercises 624 Integrative Exercises 626 Design an Experiment 627

- ▲ A Closer Look Using Spectroscopic Methods to Measure Reaction Rates: Beer's Law 582
- ▲ Chemistry Put to Work Methyl Bromide in the Atmosphere 592
- ▲ Chemistry Put to Work Catalytic Converters 610
- ▲ Chemistry and Life Nitrogen Fixation and Nitrogenase 612

15 Chemical Equilibrium 628

- 15.1 The Concept of Equilibrium 630
- 15.2 The Equilibrium Constant 632

 Evaluating K_c 634 Equilibrium Constants in Terms of Pressure, K_p 635 Equilibrium Constants and Units 636
- 15.3 Understanding and Working with
 Equilibrium Constants 637
 The Magnitude of Equilibrium Constants 637
 The Direction of the Chemical Equation
 and K 639 Relating Chemical Equation
 Stoichiometry and Equilibrium Constants 639
- 15.4 Heterogeneous Equilibria 641
- 15.5 Calculating Equilibrium Constants 644
- 15.6 Applications of Equilibrium Constants 646
 Predicting the Direction of Reaction 646
 Calculating Equilibrium Concentrations 648
- 15.7 Le Châtelier's Principle 650

Change in Reactant or Product
Concentration 651 Effects of Volume and
Pressure Changes 652 Effect of Temperature
Changes 654 The Effect of Catalysts 657

Chapter Summary and Key Terms 660 Learning Outcomes 660 Key Equations 661 Exercises 661 Additional Exercises 666 Integrative Exercises 668 Design an Experiment 669

- ▲ Chemistry Put to Work The Haber Process 633
- ▲ Chemistry Put to Work Controlling Nitric Oxide Emissions 659

16 Acid–Base Equilibria 670

- 16.1 Acids and Bases: A Brief Review 672
- 16.2 Brønsted-Lowry Acids and Bases 673

The H⁺ Ion in Water 673 Proton-Transfer Reactions 673 Conjugate Acid-Base Pairs 674 Relative Strengths of Acids and Bases 676

- 16.3 The Autoionization of Water 678
 The Ion Product of Water 679
- 16.4 The pH Scale 680
 pOH and Other "p" Scales 682 Measuring
 pH 683
- 16.5 Strong Acids and Bases 684
 Strong Acids 684 Strong Bases 685
- 16.6 Weak Acids 686

 Calculating K_a from pH 688 Percent

 Ionization 689 Using K_a to Calculate pH 690

 Polyprotic Acids 694
- 16.7 Weak Bases 696
 Types of Weak Bases 698
- 16.8 Relationship between K_a and K_b 699
- 16.9 Acid-Base Properties of Salt Solutions 702
 An Anion's Ability to React with Water 702
 A Cation's Ability to React with Water 702
 Combined Effect of Cation and Anion in
 Solution 704
- 16.10 Acid–Base Behavior and Chemical Structure 705

Factors That Affect Acid Strength 705 Binary Acids 706 Oxyacids 707 Carboxylic Acids 709

16.11 Lewis Acids and Bases 710

Chapter Summary and Key Terms 713 Learning Outcomes 714 Key Equations 714 Exercises 715 Additional Exercises 720 Integrative Exercises 722 Design an Experiment 723

- ▲ Chemistry Put to Work Amines and Amine Hydrochlorides 701
- ▲ Chemistry and Life The Amphiprotic Behavior of Amino Acids 709

17 Additional Aspects of Aqueous Equilibria 724

- 17.1 The Common-Ion Effect 726
- 17.2 Buffers 729

Composition and Action of Buffers 729 Calculating the pH of a Buffer 731 Buffer Capacity and pH Range 734 Addition of Strong Acids or Bases to Buffers 735

17.3 Acid-Base Titrations 738

Strong Acid–Strong Base Titrations 738 Weak Acid–Strong Base Titrations 740 Titrating with an Acid–Base Indicator 744 Titrations of Polyprotic Acids 746

PREFACE

To the Instructor

Philosophy

We authors of Chemistry: The Central Science are delighted and honored that you have chosen us as your instructional partners for your general chemistry class. We have all been active researchers who appreciate both the learning and the discovery aspects of the chemical sciences. We have also all taught general chemistry many times. Our varied, wide-ranging experiences have formed the basis of the close collaborations we have enjoyed as coauthors. In writing our book, our focus is on the students: we try to ensure that the text is not only accurate and up-to-date but also clear and readable. We strive to convey the breadth of chemistry and the excitement that scientists experience in making new discoveries that contribute to our understanding of the physical world. We want the student to appreciate that chemistry is not a body of specialized knowledge that is separate from most aspects of modern life, but central to any attempt to address a host of societal concerns, including renewable energy, environmental sustainability, and improved human health.

Publishing the thirteenth edition of this text bespeaks an exceptionally long record of successful textbook writing. We are appreciative of the loyalty and support the book has received over the years, and mindful of our obligation to justify each new edition. We begin our approach to each new edition with an intensive author retreat, in which we ask ourselves the deep questions that we must answer before we can move forward. What justifies yet another edition? What is changing in the world not only of chemistry, but with respect to science education and the qualities of the students we serve? The answer lies only partly in the changing face of chemistry itself. The introduction of many new technologies has changed the landscape in the teaching of sciences at all levels. The use of the Internet in accessing information and presenting learning materials has markedly changed the role of the textbook as one element among many tools for student learning. Our challenge as authors is to maintain the text as the primary source of chemical knowledge and practice, while at the same time integrating it with the new avenues for learning made possible by technology and the Internet. This edition incorporates links to a number of those new methodologies, including use of the Internet, computer-based classroom tools, such as Learning Catalytics™, a cloud-based active learning analytics and assessment system, and web-based tools, particularly MasteringChemistry®, which is continually evolving to provide more effective means of testing and evaluating student performance, while giving the student immediate and helpful feedback. In past versions, MasteringChemistry® provided feedback only on a question level. Now with Knewtonenhanced adaptive follow-up assignments, and Dynamic Study Modules, MasteringChemistry® continually adapts to each student, offering a personalized learning experience.

As authors, we want this text to be a central, indispensable learning tool for students. Whether as a physical book or in electronic form, it can be carried everywhere and used at any time. It is the one place students can go to obtain the information outside of the classroom needed for learning, skill development, reference, and test preparation. The text, more effectively than any other instrument, provides the depth of coverage and coherent background in modern chemistry that students need to serve their professional interests and, as appropriate, to prepare for more advanced chemistry courses.

If the text is to be effective in supporting your role as instructor, it must be addressed to the students. We have done our best to keep our writing clear and interesting and the book attractive and well illustrated. The book has numerous in-text study aids for students, including carefully placed descriptions of problem-solving strategies. We hope that our cumulative experiences as teachers is evident in our pacing, choice of examples, and the kinds of study aids and motivational tools we have employed. We believe students are more enthusiastic about learning chemistry when they see its importance relative to their own goals and interests; therefore, we have highlighted many important applications of chemistry in everyday life. We hope you make use of this material.

It is our philosophy, as authors, that the text and all the supplementary materials provided to support its use must work in concert with you, the instructor. A textbook is only as useful to students as the instructor permits it to be. This book is replete with features that can help students learn and that can guide them as they acquire both conceptual understanding and problem-solving skills. There is a great deal here for the students to use, too much for all of it to be absorbed by any one student. You will be the guide to the best use of the book. Only with your active help will the students be able to utilize most effectively all that the text and its supplements offer. Students care about grades, of course, and with encouragement they will also become interested in the subject matter and care about learning. Please consider emphasizing features of the book that can enhance student appreciation of chemistry, such as the Chemistry Put to Work and Chemistry and Life boxes that show how chemistry impacts modern life and its relationship to health and life processes. Learn to use, and urge students to use, the rich online resources available. Emphasize conceptual understanding and place less emphasis on simple manipulative, algorithmic problem solving.

What Is New in This Edition?

A great many changes have been made in producing this thirteenth edition. We have continued to improve upon the art program, and new features connected with the art have been introduced. Many figures in the book have undergone modification, and dozens of new figures have been introduced.

A systematic effort has been made to place explanatory labels directly into figures to guide the student. New designs have been employed to more closely integrate photographic materials into figures that convey chemical principles.

We have continued to explore means for more clearly and directly addressing the issue of concept learning. It is well established that conceptual misunderstandings, which impede student learning in many areas, are difficult to correct. We have looked for ways to identify and correct misconceptions via the worked examples in the book, and in the accompanying practice exercises. Among the more important changes made in the new edition, with this in mind, are:

- A major new feature of this edition is the addition of a second Practice Exercise to accompany each Sample Exercise within the chapters. The majority of new *Practice Exercises* are of the multiple-choice variety, which enable feedback via MasteringChemistry®. The correct answers to select Practice Exercises are given in an appendix, and guidance for correcting wrong answers is provided in MasteringChemistry®. The new Practice Exercise feature adds to the aids provided to students for mastering the concepts advanced in the text and rectifying conceptual misunderstandings. The enlarged practice exercise materials also further cement the relationship of the text to the online learning materials. At the same time, they offer a new supportive learning experience for all students, regardless of whether the MasteringChemistry® program is used.
- A second major innovation in this edition is the Design An Experiment feature, which appears as a final exercise in all chapters beginning with Chapter 3, as well as in MasteringChemistry®. The Design an Experiment exercise is a departure from the usual kinds of end-of-chapter exercises in that it is inquiry based, open ended, and tries to stimulate the student to "think like a scientist." Each exercise presents the student with a scenario in which various unknowns require investigation. The student is called upon to ponder how experiments might be set up to provide answers to particular questions about a system, and/ or test plausible hypotheses that might account for a set of observations. The aim of the Design an Experiment exercises is to foster critical thinking. We hope that they will be effective in active learning environments, which include classroom-based work and discussions, but they are also suitable for individual student work. There is no one right way to solve these exercises, but we authors offer some ideas in an online Instructor's Resource Manual, which will include results from class testing and analysis of student responses.
- The *Go Figure* exercises introduced in the twelfth edition proved to be a popular innovation, and we have expanded on its use. This feature poses a question that students can answer by examining the figure. These questions encourage students to actually study the figure and understand its primary message. Answers to the *Go Figure* questions are provided in the back of the text.
- The popular *Give It Some Thought (GIST)* questions embedded in the text have been expanded by improvements

- in some of the existing questions and addition of new ones. The answers to all the GIST items are provided in the back of the text.
- New end-of-chapter exercises have been added, and many of those carried over from the twelfth edition have been significantly revised. Analysis of student responses to the twelfth edition questions in MasteringChemistry® helped us identify and revise or create new questions, prompting improvements and eliminations of some questions. Additionally, analysis of usage of MasteringChemistry® has enhanced our understanding of the ways in which instructors and students have used the end-of-chapter and MasteringChemistry® materials. This, in turn, has led to additional improvements to the content within the text and in the MasteringChemistry® item library. At the end of each chapter, we list the Learning Outcomes that students should be able to perform after studying each section. End-of-chapter exercises, both in the text and in MasteringChemistry® offer ample opportunities for students to assess mastery of learning outcomes. We trust the Learning Outcomes will help you organize your lectures and tests as the course proceeds.

Organization and Contents

The first five chapters give a largely macroscopic, phenomenological view of chemistry. The basic concepts introduced—such as nomenclature, stoichiometry, and thermochemistry—provide necessary background for many of the laboratory experiments usually performed in general chemistry. We believe that an early introduction to thermochemistry is desirable because so much of our understanding of chemical processes is based on considerations of energy changes. Thermochemistry is also important when we come to a discussion of bond enthalpies. We believe we have produced an effective, balanced approach to teaching thermodynamics in general chemistry, as well as providing students with an introduction to some of the global issues involving energy production and consumption. It is no easy matter to walk the narrow pathway between—on the one hand—trying to teach too much at too high a level and—on the other hand—resorting to oversimplifications. As with the book as a whole, the emphasis has been on imparting conceptual understanding, as opposed to presenting equations into which students are supposed to plug numbers.

The next four chapters (Chapters 6–9) deal with electronic structure and bonding. We have largely retained our presentation of atomic orbitals. For more advanced students, Closer Look boxes in Chapters 6 and 9 highlight radial probability functions and the phases of orbitals. Our approach of placing this latter discussion in a Closer Look box in Chapter 9 enables those who wish to cover this topic to do so, while others may wish to bypass it. In treating this topic and others in Chapters 7 and 9, we have materially enhanced the accompanying figures to more effectively bring home their central messages.

In Chapters 10–13, the focus of the text changes to the next level of the organization of matter: examining the states of

matter. Chapters 10 and 11 deal with gases, liquids, and intermolecular forces, as in earlier editions. Chapter 12 is devoted to solids, presenting an enlarged and more contemporary view of the solid state as well as of modern materials. The chapter provides an opportunity to show how abstract chemical bonding concepts impact real-world applications. The modular organization of the chapter allows you to tailor your coverage to focus on materials (semiconductors, polymers, nanomaterials, and so forth) that are most relevant to your students and your own interests. Chapter 13 treats the formation and properties of solutions in much the same manner as the previous edition.

The next several chapters examine the factors that determine the speed and extent of chemical reactions: kinetics (Chapter 14), equilibria (Chapters 15–17), thermodynamics (Chapter 19), and electrochemistry (Chapter 20). Also in this section is a chapter on environmental chemistry (Chapter 18), in which the concepts developed in preceding chapters are applied to a discussion of the atmosphere and hydrosphere. This chapter has increasingly come to be focused on green chemistry and the impacts of human activities on Earth's water and atmosphere.

After a discussion of nuclear chemistry (Chapter 21), the book ends with three survey chapters. Chapter 22 deals with nonmetals, Chapter 23 with the chemistry of transition metals, including coordination compounds, and Chapter 24 with the chemistry of organic compounds and elementary biochemical themes. These final four chapters are developed in a parallel fashion and can be covered in any order.

Our chapter sequence provides a fairly standard organization, but we recognize that not everyone teaches all the topics in the order we have chosen. We have therefore made sure that instructors can make common changes in teaching sequence with no loss in student comprehension. In particular, many instructors prefer to introduce gases (Chapter 10) after stoichiometry (Chapter 3) rather than with states of matter. The chapter on gases has been written to permit this change with *no* disruption in the flow of material. It is also possible to treat balancing redox equations (Sections 20.1 and 20.2) earlier, after the introduction of redox reactions in Section 4.4. Finally, some instructors like to cover organic chemistry (Chapter 24) right after bonding (Chapters 8 and 9). This, too, is a largely seamless move.

We have brought students into greater contact with descriptive organic and inorganic chemistry by integrating examples throughout the text. You will find pertinent and relevant examples of "real" chemistry woven into all the chapters to illustrate principles and applications. Some chapters, of course, more directly address the "descriptive" properties of elements and their compounds, especially Chapters 4, 7, 11, 18, and 22–24. We also incorporate descriptive organic and inorganic chemistry in the end-of-chapter exercises.

Changes in This Edition

The **What is New in This Edition** section on pp. xx-xxi details changes made throughout the new edition. Beyond a mere listing, however, it is worth dwelling on the general goals we set forth in formulating this new edition. *Chemistry: The Central*

Science has traditionally been valued for its clarity of writing, its scientific accuracy and currency, its strong end-of-chapter exercises, and its consistency in level of coverage. In making changes, we have made sure not to compromise these characteristics, and we have also continued to employ an open, clean design in the layout of the book.

The art program for this thirteenth edition has continued the trajectory set in the twelfth edition: to make greater and more effective use of the figures as learning tools, by drawing the reader more directly into the figure. The art itself has continued to evolve, with modifications of many figures and additions or replacements that teach more effectively. The *Go Figure* feature has been expanded greatly to include a larger number of figures. In the same vein, we have added to the *Give it Some Thought* feature, which stimulates more thoughtful reading of the text and fosters critical thinking.

We provide a valuable overview of each chapter under the What's Ahead banner. Concept links () continue to provide easy-to-see cross-references to pertinent material covered earlier in the text. The essays titled Strategies in Chemistry, which provide advice to students on problem solving and "thinking like a chemist," continue to be an important feature. For example, the new Strategies in Chemistry essay at the end of Chapter 3 introduces the new Design an Experiment feature and provides a worked out example as guidance.

We have continued to emphasize conceptual exercises in the end-of-chapter exercise materials. The well-received Visualizing Concepts exercise category has been continued in this edition. These exercises are designed to facilitate concept understanding through use of models, graphs, and other visual materials. They precede the regular end-of-chapter exercises and are identified in each case with the relevant chapter section number. A generous selection of Integrative Exercises, which give students the opportunity to solve problems that integrate concepts from the present chapter with those of previous chapters, is included at the end of each chapter. The importance of integrative problem solving is highlighted by the Sample Integrative Exercise, which ends each chapter beginning with Chapter 4. In general, we have included more conceptual endof-chapter exercises and have made sure that there is a good representation of somewhat more difficult exercises to provide a better mix in terms of topic and level of difficulty. Many of the exercises have been restructured to facilitate their use in MasteringChemistry®. We have made extensive use of the metadata from student use of MasteringChemistry® to analyze end-ofchapter exercises and make appropriate changes, as well as to develop Learning Outcomes for each chapter.

New essays in our well-received *Chemistry Put to Work* and *Chemistry and Life* series emphasize world events, scientific discoveries, and medical breakthroughs that bear on topics developed in each chapter. We maintain our focus on the positive aspects of chemistry without neglecting the problems that can arise in an increasingly technological world. Our goal is to help students appreciate the real-world perspective of chemistry and the ways in which chemistry affects their lives.

It is perhaps a natural tendency for chemistry textbooks to grow in length with succeeding editions, but it is one that we have resisted. There are, nonetheless, many new items in this edition, mostly ones that replace other material considered less pertinent. Here is a list of several significant changes in content:

In Chapter 1, the *Closer Look* box on the scientific method has been rewritten. The *Chemistry Put to Work* box, dealing with *Chemistry in the News*, has been completely rewritten, with items that describe diverse ways in which chemistry intersects with the affairs of modern society. The *Chapter Summary* and *Learning Outcomes* sections at the end of the chapter have been rewritten for ease of use by both instructor and student, in this and all chapters in the text. Similarly, the exercises have been thoroughly vetted, modified where this was called for and replaced or added to, here and in all succeeding chapters.

In Chapter 3, graphic elements highlighting the correct approach to problem solving have been added to *Sample Exercises* on calculating an empirical formula from mass percent of the elements present, combustion analysis, and calculating a theoretical yield.

Chapter 5 now presents a more explicit discussion of combined units of measurement, an improved introduction to enthalpy, and more consistent use of color in art.

Changes in Chapter 6 include a significant revision of the discussion of the energy levels of the hydrogen atom, including greater clarity on absorption versus emission processes. There is also a new *Closer Look* box on *Thought Experiments and Schrödinger's Cat*, which gives students a brief glimpse of some of the philosophical issues in quantum mechanics and also connects to the 2012 Nobel Prize in Physics.

In Chapter 7, the emphasis on conceptual thinking was enhanced in several ways: the section on effective nuclear charge was significantly revised to include a classroom-tested analogy, the number of *Go Figure* features was increased substantially, and new end-of-chapter exercises emphasize critical thinking and understanding concepts. In addition, the *Chemistry Put to Work* box on lithium-ion batteries was updated and revised to include discussion of current issues in using these batteries. Finally, the values of ionic radii were revised to be consistent with a recent research study of the best values for these radii.

In Chapter 9, which is one of the most challenging for students, we continue to refine our presentation based on our classroom experience. Twelve new *Go Figure* exercises will stimulate more student thought in a chapter with a large amount of graphic material. The discussion of molecular geometry was made more conceptually oriented. The section on delocalized bonding was completely revised to provide what we believe will be a better introduction that students will find useful in organic chemistry. The *Closer Look* box on phases in orbitals was revamped with improved artwork. We also increased the number of end-of-chapter exercises, especially in the area of molecular orbital theory. The *Design an Experiment* feature in this chapter gives the students the opportunity to explore color and conjugated π systems.

Chapter 10 contains a new *Sample Exercise* that walks the student through the calculations that are needed to understand Torricelli's barometer. Chapter 11 includes an improved definition of hydrogen bonding and updated data for the strengths

of intermolecular attractions. Chapter 12 includes the latest updates to materials chemistry, including plastic electronics. New material on the diffusion and mean free path of colloids in solution is added to Chapter 13, making a connection to the diffusion of gas molecules from Chapter 10.

In Chapter 14, ten new *Go Figure* exercises have been added to reinforce many of the concepts presented as figures and graphs in the chapter. The *Design an Experiment* exercise in the chapter connects strongly to the *Closer Look* box on Beer's Law, which is often the basis for spectrometric kinetics experiments performed in the general chemistry laboratory.

The presentation in Chapter 16 was made more closely tied to that in Chapter 15, especially through the use of more initial/change/equilibrium (ICE) charts. The number of conceptual end-of-chapter exercises, including *Visualizing Concepts* features, was increased significantly.

Chapter 17 offers improved clarity on how to make buffers, and when the Henderson–Hasselbalch equation may not be accurate. Chapter 18 has been extensively updated to reflect changes in this rapidly evolving area of chemistry. Two *Closer Look* boxes have been added; one dealing with the shrinking level of water in the Ogallala aquifer and a second with the potential environmental consequences of hydraulic fracking. In Chapter 20, the description of Li-ion batteries has been significantly expanded to reflect the growing importance of these batteries, and a new *Chemistry Put to Work* box on batteries for hybrid and electric vehicles has been added.

Chapter 21 was updated to reflect some of the current issues in nuclear chemistry and more commonly used nomenclature for forms of radiation are now used. Chapter 22 includes an improved discussion of silicates.

In Chapter 23, the section on crystal-field theory (Section 23.6) has undergone considerable revision. The description of how the *d*-orbital energies of a metal ion split in a tetrahedral crystal field has been expanded to put it on par with our treatment of the octahedral geometry, and a new *Sample Exercise* that effectively integrates the links between color, magnetism, and the spectrochemical series has been added. Chapter 24's coverage of organic chemistry and biochemistry now includes oxidation–reduction reactions that organic chemists find most relevant.

To the Student

Chemistry: The Central Science, Thirteenth Edition, has been written to introduce you to modern chemistry. As authors, we have, in effect, been engaged by your instructor to help you learn chemistry. Based on the comments of students and instructors who have used this book in its previous editions, we believe that we have done that job well. Of course, we expect the text to continue to evolve through future editions. We invite you to write to tell us what you like about the book so that we will know where we have helped you most. Also, we would like to learn of any shortcomings so that we might further improve the book in subsequent editions. Our addresses are given at the end of the Preface.

Advice for Learning and Studying Chemistry

Learning chemistry requires both the assimilation of many concepts and the development of analytical skills. In this text, we have provided you with numerous tools to help you succeed in both tasks. If you are going to succeed in your chemistry course, you will have to develop good study habits. Science courses, and chemistry in particular, make different demands on your learning skills than do other types of courses. We offer the following tips for success in your study of chemistry:

Don't fall behind! As the course moves along, new topics will build on material already presented. If you don't keep up in your reading and problem solving, you will find it much harder to follow the lectures and discussions on current topics. Experienced teachers know that students who read the relevant sections of the text *before* coming to a class learn more from the class and retain greater recall. "Cramming" just before an exam has been shown to be an ineffective way to study any subject, chemistry included. So now you know. How important to you, in this competitive world, is a good grade in chemistry?

Focus your study. The amount of information you will be expected to learn can sometimes seem overwhelming. It is essential to recognize those concepts and skills that are particularly important. Pay attention to what your instructor is emphasizing. As you work through the Sample Exercises and homework assignments, try to see what general principles and skills they employ. Use the What's Ahead feature at the beginning of each chapter to help orient yourself to what is important in each chapter. A single reading of a chapter will simply not be enough for successful learning of chapter concepts and problem-solving skills. You will need to go over assigned materials more than once. Don't skip the Give It Some Thought and Go Figure features, Sample Exercises, and Practice Exercises. They are your guides to whether you are learning the material. They are also good preparation for test-taking. The Learning Outcomes and Key Equations at the end of the chapter should help you focus your study.

Keep good lecture notes. Your lecture notes will provide you with a clear and concise record of what your instructor regards as the most important material to learn. Using your lecture notes in conjunction with this text is the best way to determine which material to study.

Skim topics in the text before they are covered in lecture. Reviewing a topic before lecture will make it easier for you to take good notes. First read the *What's Ahead* points and the end-of-chapter *Summary*; then quickly read through the chapter, skipping Sample Exercises and supplemental sections. Paying attention to the titles of sections and subsections gives you

a feeling for the scope of topics. Try to avoid thinking that you must learn and understand everything right away.

You need to do a certain amount of preparation before lecture. More than ever, instructors are using the lecture period not simply as a one-way channel of communication from teacher to student. Rather, they expect students to come to class ready to work on problem solving and critical thinking. Coming to class unprepared is not a good idea for any lecture environment, but it certainly is not an option for an active learning classroom if you aim to do well in the course.

After lecture, carefully read the topics covered in class. As you read, pay attention to the concepts presented and to the application of these concepts in the *Sample Exercises*. Once you think you understand a *Sample Exercise*, test your understanding by working the accompanying *Practice Exercise*.

Learn the language of chemistry. As you study chemistry, you will encounter many new words. It is important to pay attention to these words and to know their meanings or the entities to which they refer. Knowing how to identify chemical substances from their names is an important skill; it can help you avoid painful mistakes on examinations. For example, "chlorine" and "chloride" refer to very different things.

Attempt the assigned end-of-chapter exercises. Working the exercises selected by your instructor provides necessary practice in recalling and using the essential ideas of the chapter. You cannot learn merely by observing; you must be a participant. In particular, try to resist checking the *Student Solutions Manual* (if you have one) until you have made a sincere effort to solve the exercise yourself. If you get stuck on an exercise, however, get help from your instructor, your teaching assistant, or another student. Spending more than 20 minutes on a single exercise is rarely effective unless you know that it is particularly challenging.

Learn to think like a scientist. This book is written by scientists who love chemistry. We encourage you to develop your critical thinking skills by taking advantage of new features in this edition, such as exercises that focus on conceptual learning, and the *Design an Experiment* exercises.

Use online resources. Some things are more easily learned by discovery, and others are best shown in three dimensions. If your instructor has included MasteringChemistry® with your book, take advantage of the unique tools it provides to get the most out of your time in chemistry.

The bottom line is to work hard, study effectively, and use the tools available to you, including this textbook. We want to help you learn more about the world of chemistry and why chemistry is the central science. If you really learn chemistry, you can be the life of the party, impress your friends and parents, and ... well, also pass the course with a good grade.

Acknowledgments

The production of a textbook is a team effort requiring the involvement of many people besides the authors who contributed hard work and talent to bring this edition to life. Although their names don't appear on the cover of the book, their creativity, time, and support have been instrumental in all stages of its development and production.

Each of us has benefited greatly from discussions with colleagues and from correspondence with instructors and stu-

dents both here and abroad. Colleagues have also helped immensely by reviewing our materials, sharing their insights, and providing suggestions for improvements. On this edition, we were particularly blessed with an exceptional group of accuracy checkers who read through our materials looking for both technical inaccuracies and typographical errors.

XXVIII PREFACE

We would also like to express our gratitude to our many team members at Pearson whose hard work, imagination, and commitment have contributed so greatly to the final form of this edition: Terry Haugen, our senior editor, who has brought energy and imagination to this edition as he has to earlier ones; Chris Hess, our chemistry editor, for many fresh ideas and his unflagging enthusiasm, continuous encouragement, and support; Jennifer Hart, Director of Development, who has brought her experience and insight to oversight of the entire project; Jessica Moro, our project editor, who very effectively coordinated the scheduling and tracked the multidimensional deadlines that come with a project of this magnitude; Jonathan Cottrell our marketing manager, for his energy, enthusiasm, and creative promotion of our text; Carol Pritchard-Martinez, our development editor, whose depth of experience, good judgment, and careful attention to detail were invaluable to this revision, especially in keeping us on task in terms of consistency and student understanding; Donna, our copy editor, for her keen eye; Beth Sweeten, our project manager, and Gina Cheselka, who managed the complex responsibilities of bringing the design, photos, artwork, and writing together with efficiency and good cheer. The Pearson team is a first-class operation.

There are many others who also deserve special recognition, including the following: Greg Johnson, our production editor, who skillfully kept the process moving and us authors on track; Kerri Wilson, our photo researcher, who was so effective in finding photos to bring chemistry to life for students; and Roxy Wilson (University of Illinois), who so ably coordinated the difficult job of working out solutions to the end-of-chapter exercises. Finally, we wish to thank our families and friends for their love, support, encouragement, and patience as we brought this thirteenth edition to completion.

List of Resources

For Students

MasteringChemistry®

(http://www.masteringchemistry.com)

MasteringChemistry® is the most effective, widely used online tutorial, homework and assessment system for chemistry. It helps instructors maximize class time with customizable, easy-to-assign, and automatically graded assessments that motivate students to learn outside of class and arrive prepared for lecture. These assessments can easily be customized and personalized by instructors to suit their individual teaching style. The powerful gradebook provides unique insight into student and class performance even before the first test. As a result, instructors can spend class time where students need it most.

Pearson eText The integration of Pearson eText within MasteringChemistry® gives students with eTexts easy access to the electronic text when they are logged into MasteringChemistry®. Pearson eText pages look exactly like the printed text, offering powerful new functionality for students and instructors. Users can create notes, highlight text in different colors, create bookmarks, zoom, view in single-page or two-page view, and more.

Students Guide (0-321-94928-5) Prepared by James C. Hill of California State University. This book assists students through the text material with chapter overviews, learning objectives, a review of key terms, as well as self-tests with answers and explanations. This edition also features MCAT practice questions.

Solutions to Red Exercises (0-321-94926-9) Prepared by Roxy Wilson of the University of Illinois, Urbana-Champaign. Full solutions to all the red-numbered exercises in the text are provided. (Short answers to red exercises are found in the appendix of the text.)

Solutions to Black Exercises (0-321-94927-7) Prepared by Roxy Wilson of the University of Illinois, Urbana-Champaign. Full solutions to all the black-numbered exercises in the text are provided.

Laboratory Experiments (0-321-94991-9) Prepared by John H. Nelson of the University of Nevada, and Michael Lufaso of the University of North Florida with contributions by Matthew Stoltzfus of The Ohio State University. This manual contains 40 finely tuned experiments chosen to introduce students to basic lab techniques and to illustrate core chemical principles. This new edition has been revised with the addition of four brand new experiments to correlate more tightly with the text. You can also customize these labs through Catalyst, our custom database program. For more information, visit http://www.pearsoncustom.com/custom-library/

For Instructors

Solutions to Exercises (0-321-94925-0) Prepared by Roxy Wilson of the University of Illinois, Urbana-Champaign. This manual contains all end-of-chapter exercises in the text. With an instructor's permission, this manual may be made available to students.

Online Instructor Resource Center (0-321-94923-4) This resource provides an integrated collection of resources to help instructors make efficient and effective use of their time. It features all artwork from the text, including figures and tables in PDF format for high-resolution printing, as well as five prebuilt PowerPoint™ presentations. The first presentation contains the images embedded within PowerPoint slides. The second includes a complete lecture outline that is modifiable by the user. The final three presentations contain worked "in-chapter" sample exercises and questions to be used with Classroom Response Systems. The Instructor Resource Center also contains movies, animations, and electronic files of the Instructor Resource Manual, as well as the Test Item File.

TestGen Testbank (0-321-94924-2) Prepared by Andrea Leonard of the University of Louisiana. The Test Item File now provides a selection of more than 4,000 test questions with 200 new questions in the thirteenth edition and 200 additional algorithmic questions.

Online Instructor Resource Manual (0-321-94929-3) Prepared by Linda Brunauer of Santa Clara University and Elzbieta Cook of Louisiana State University. Organized by chapter, this manual offers detailed lecture outlines and complete descriptions of all available lecture demonstrations, interactive media assets, common student misconceptions, and more.

Annotated Instructor's Edition to Laboratory Experiments (0-321-98608-3) Prepared by John H. Nelson of the University of Nevada, and Michael Lufaso of the University of North Florida with contributions by Matthew Stoltzfus of the Ohio State University. This AIE combines the full student lab manual with appendices covering the proper disposal of chemical waste, safety instructions for the lab, descriptions of standard lab equipment, answers to questions, and more.

About the Authors

THE BROWN/LEMAY/BURSTEN/
MURPHY/WOODWARD/STOLTZFUS
AUTHOR TEAM values collaboration as an integral component to overall success. While each author brings unique talent, research interests, and teaching experiences, the team works together to review and develop the entire text. It is this collaboration that keeps the content ahead of educational trends and contributes to continuous innovations in teaching and learning throughout the text and technology. Some of the new key features in the thirteenth edition and accompanying MasteringChemistry® course are highlighted on the following pages.

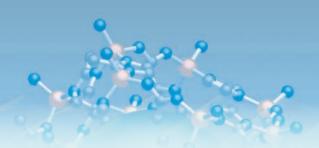

THEODORE L. BROWN received his Ph.D. from Michigan State University in 1956. Since then, he has been a member of the faculty of the University of Illinois, Urbana-Champaign, where he is now Professor of Chemistry, Emeritus. He served as Vice Chancellor for Research, and Dean of The Graduate College, from 1980 to 1986, and as Founding Director of the Arnold and Mabel Beckman Institute for Advanced Science and Technology from 1987 to 1993. Professor Brown has been an Alfred P. Sloan Foundation Research Fellow and has been awarded a Guggenheim Fellowship. In 1972 he was awarded the American Chemical Society Award for Research in Inorganic Chemistry and received the American Chemical Society Award for Distinguished Service in the Advancement of Inorganic Chemistry in 1993. He has been elected a Fellow of the American Association for the Advancement of Science, the American Academy of Arts and Sciences, and the American Chemical Society.

H. EUGENE LEMAY, JR., received his B.S. degree in Chemistry from Pacific Lutheran University (Washington) and his Ph.D. in Chemistry in 1966 from the University of Illinois, Urbana-Champaign. He then joined the faculty of the University of Nevada, Reno, where he is currently Professor of Chemistry, Emeritus. He has enjoyed Visiting Professorships at the University of North Carolina at Chapel Hill, at the University College of Wales in Great Britain, and at the University of California, Los Angeles. Professor LeMay is a popular and effective teacher, who has taught thousands of students during more than 40 years of university teaching. Known for the clarity of his lectures and his sense of humor, he has received several teaching awards, including the University Distinguished Teacher of the Year Award (1991) and the first Regents' Teaching Award given by the State of Nevada Board of Regents (1997).

BRUGE E. BURSTEN received his Ph.D. in Chemistry from the University of Wisconsin in 1978. After two years as a National Science Foundation Postdoctoral Fellow at Texas A&M University, he joined the faculty of The Ohio State University, where he rose to the rank of Distinguished University Professor. In 2005, he moved to the University of Tennessee, Knoxville, as Distinguished Professor of Chemistry and Dean of the College of Arts and Sciences. Professor Bursten has been a Camille and Henry Dreyfus Foundation Teacher-Scholar and an Alfred P. Sloan Foundation Research Fellow, and he is a Fellow of both the American Association for the Advancement of Science and the American Chemical Society. At Ohio State he has received the University Distinguished Teaching Award in 1982 and 1996, the Arts and Sciences Student Council Outstanding Teaching Award in 1984, and the University Distinguished Scholar Award in 1990. He received the Spiers Memorial Prize and Medal of the Royal Society of Chemistry in 2003, and the Morley Medal of the Cleveland Section of the American Chemical Society in 2005. He was President of the American Chemical Society for 2008. In addition to his teaching and service activities, Professor Bursten's research program focuses on compounds of the transition-metal and actinide elements.

CATHERINE J. MURPHY received two B.S. degrees, one in Chemistry and one in Biochemistry, from the University of Illinois, Urbana-Champaign, in 1986. She received her Ph.D. in Chemistry from the University of Wisconsin in 1990. She was a National Science Foundation and National Institutes of Health Postdoctoral Fellow at the California Institute of Technology from 1990 to 1993. In 1993, she joined the faculty of the University of South Carolina, Columbia, becoming the Guy F. Lipscomb Professor of Chemistry in 2003. In 2009 she moved to the University of Illinois, Urbana-Champaign, as the Peter C. and Gretchen Miller Markunas Professor of Chemistry. Professor Murphy has been honored for both research and teaching as a Camille Dreyfus Teacher-Scholar, an Alfred P. Sloan Foundation Research Fellow, a Cottrell Scholar of the Research Corporation, a National Science Foundation CAREER Award winner, and a subsequent NSF Award for Special Creativity. She has also received a USC Mortar Board Excellence in Teaching Award, the USC Golden Key Faculty Award for Creative Integration of Research and Undergraduate Teaching, the USC Michael J. Mungo Undergraduate Teaching Award, and the USC Outstanding Undergraduate Research Mentor Award. Since 2006, Professor Murphy has served as a Senior Editor for the Journal of Physical Chemistry. In 2008 she was elected a Fellow of the American Association for the Advancement of Science. Professor Murphy's research program focuses on the synthesis and optical properties of inorganic nanomaterials, and on the local structure and dynamics of the DNA double helix.

PATRICK M. WOODWARD received B.S. degrees in both Chemistry and Engineering from Idaho State University in 1991. He received a M.S. degree in Materials Science and a Ph.D. in Chemistry from Oregon State University in 1996. He spent two years as a postdoctoral researcher in the Department of Physics at Brookhaven National Laboratory. In 1998, he joined the faculty of the Chemistry Department at The Ohio State University where he currently holds the rank of Professor. He has enjoyed visiting professorships at the University of Bordeaux in France and the University of Sydney in Australia. Professor Woodward has been an Alfred P. Sloan Foundation Research Fellow and a National Science Foundation CAREER Award winner. He currently serves as an Associate Editor to the Journal of Solid State Chemistry and as the director of the Ohio REEL program, an NSF-funded center that works to bring authentic research experiments into the laboratories of first- and second-year chemistry classes in 15 colleges and universities across the state of Ohio. Professor Woodward's research program focuses on understanding the links between bonding, structure, and properties of solid-state inorganic functional materials.

MATTHEW W. STOLTZFUS received his B.S. degree in Chemistry from Millersville University in 2002 and his Ph. D. in Chemistry in 2007 from The Ohio State University. He spent two years as a teaching postdoctoral assistant for the Ohio REEL program, an NSF-funded center that works to bring authentic research experiments into the general chemistry lab curriculum in 15 colleges and universities across the state of Ohio. In 2009, he joined the faculty of Ohio State where he currently holds the position of Chemistry Lecturer. In addition to lecturing general chemistry, Stoltzfus accepted the Faculty Fellow position for the Digital First Initiative, inspiring instructors to offer engaging digital learning content to students through emerging technology. Through this initiative, he developed an iTunes U general chemistry course, which has attracted over 120,000 students from all over the world. Stoltzfus has received several teaching awards, including the inaugural Ohio State University 2013 Provost's Award for Distinguished Teaching by a Lecturer and he is recognized as an Apple Distinguished Educator.

Data-Driven Analytics

A New Direction in Chemical Education

uthors traditionally revise roughly 25% of the end of chapter questions when producing a new edition. These changes typically involve modifying numerical variables/identities of chemical formulas to make them "new" to the next batch of students. While these changes are appropriate for the printed version of the text, one of the strengths of MasteringChemistry* is its ability to randomize variables so that every student receives a "different" problem. Hence, the effort which authors have historically put into changing variables can now be used to improve questions.

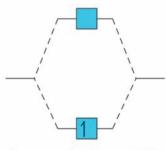

In order to make informed decisions, the author team consulted the massive reservoir of data available through MasteringChemistry* to revise their question bank. In particular, they analyized which problems were frequently assigned and why; they paid careful attention to the amount of time it took students to work through a problem (flagging those that took longer than expected) and they observed the wrong answer submissions and hints used (a measure used to calculate the difficulty of problems). This "metadata" served as a starting point for the discussion of which end of chapter questions should be changed.

For example, the breadth of ideas presented in Chapter 9 challenges students to understand three-dimensional visualization while simultaneously introducing several new concepts (particularly VSEPR, hybrids, and Molecular Orbital theory) that challenge their critical thinking skills. In revising the exercises for the chapter, the authors drew on the metadata as well as their own experience in assigning Chapter 9 problems in Mastering Chemistry. From these analyses, we were able to articulate two general revision guidelines.

1. Improve coverage of topic areas that were underutilized: In Chapter 9, the authors noticed that there was a particularly low usage rate for questions concerning Molecular Orbital Theory. Based on the metadata and their own teaching experience

with Mastering, they recognized an opportunity to expand the coverage of MO theory. Two brand new exercises that emphasize the basics of MO theory were the result of this analysis including the example below. This strategy was replicated throughout the entire book.

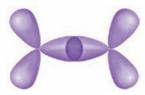

- 9.8 The drawing below shows the overlap of two hybrid orbitals to form a bond in a hydrocarbon. (a) Which of the following types of bonds is being formed: (i) C—C σ, (ii) C—C π, or (iii) C—H σ? (b) Which of the following could be the identity of the hydrocarbon: (i) CH₄, (ii) C₂H₆, (iii) C₂H₄, or (iv) C₂H₂? [Section 9.6]
- **9.10** The following is part of a molecular orbital energy-level diagram for MOs constructed from 1*s* atomic orbitals.

(a) What labels do we use for the two MOs shown? (b) For which of the following molecules or ions could this be the energy-level diagram:

$$H_2$$
, He_2 , H_2^+ , He_2^+ , or H_2^- ?

(c) What is the bond order of the molecule or ion? (d) If an electron is added to the system, into which of the MOs will it be added? [Section 9.7]

2. Revise the least assigned existing problems. Much of the appeal of MasteringChemistry* for students is the immediate feedback they get when they hit submit, which also provides an opportunity to confront any misconceptions right away. For instructors, the appeal is that these problems are automatically graded. Essay questions fail to provide these advantages since they must be graded by an instructor before a student may receive feedback. Wherever possible, we revised current essay questions to include automatically graded material.

Bottom Line: The revision of the end of chapter questions in this edition is informed by robust data-driven analytics providing a new level of pedagogically-sound assessments for your students, all while making the time they spend working these problems even more valuable.

- 9.93 An AB₅ molecule adopts the geometry shown here. (a) What is the name of this geometry? (b) Do you think there are any nonbonding electron pairs on atom A? (c) Suppose the atoms B are halogen atoms. Of which group in the periodic table is atom A a member: (i) Group 5A, (ii) Group 6A, (iii) Group 7A, (iv) Group 8A, or (v) More information is needed?
- 9.4 The molecule shown here is difluoromethane (CH₂F₂), which is used as a refrigerant called R-32. (a) Based on the structure, how many electron domains surround the C atom in this molecule? (b) Would the molecule have a nonzero dipole moment? (c) If the molecule is polar, which of the following describes the direction of the overall dipole moment vector in the molecule: (i) from the carbon atom toward a fluorine atom, (ii) from the carbon atom to a point midway between the fluorine atoms, (iii) from the carbon atom to a point midway between the hydrogen atoms, or (iv) From the carbon atom toward a hydrogen atom? [Sections 9.2 and 9.3]

Helping Students Think Like Scientists

Design an Experiment

Starting with Chapter 3, every chapter will feature a *Design an Experiment* exercise. The goal of these exercises is to challenge students to think like a scientist, imagining what kind of data needs to be collected and what sort of experimental procedures will provide them the data needed to answer the question. These exercises tend to be integrative, forcing students to draw on many of the skills they have learned in the current and previous chapters.

Strategies in Chemistry

Design an Experiment

One of the most important skills you can learn in school is how to think like a scientist. Questions such as: "What experiment might test this hypothesis?", "How do I interpret these data?", and "Do these data support the hypothesis?" are asked every day by chemists and other scientists as they go about their work.

We want you to become a good critical thinker as well as an active, logical, and curious learner. For this purpose, starting in Chapter 3, we include at the end of each chapter a special exercise called "Design an Experiment." Here is an example:

of the pan? If so, you could weigh it, and calculate the percentage of solids in milk, which would offer good evidence that milk is a mixture. If there is no residue after boiling, then you still cannot distinguish between the two possibilities.

What other experiments might you do to demonstrate that milk is a mixture? You could put a sample of milk in a centrifuge, which you might have used in a biology lab, spin your sample and observe if any solids collect at the bottom of the centrifuge tube; large molecules can be separated in this way from a mixture. Measurement of the mass of the solid at the bottom of the tube is a way to obtain a value for the % solids in milk, and also tells you that milk is indeed a mixture.

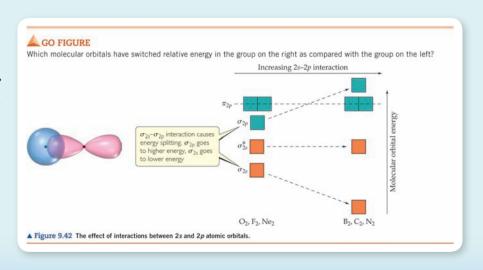

Design an Experiment topics include:

- **Ch 3:** Formation of Sulfur Oxides
- **Ch 4:** Identification of Mysterious White Powders
- **Ch 5:** Joule Experiment
- **Ch 6:** Photoelectric Effect and Electron Configurations
- **Ch 7:** Chemistry of Potassium Superoxide
- Ch 8: Benzene Resonance
- Ch 9: Colors of Organic Dyes
- Ch 10: Identification of an Unknown Noble Gas
- Ch 11: Hydraulic Fluids
- Ch 12: Polymers
- Ch 13: Volatile Solvent Molecules

- **Ch 14:** Reaction Kinetics via Spectrophotometry
- **Ch 15:** Beer's Law and Visible-Light Spectroscopy
- Ch 16: Acidity/Basicity of an Unknown Liquid
- **Ch 17:** Understanding Differences in pKa
- **Ch 18:** Effects of Fracking on Groundwater
- Ch 19: Drug Candidates and the Equilibrium Constant
- Ch 20: Voltaic Cells
- Ch 21: Discovery and Properties of Radium
- Ch 22: Identification of Unknowns
- Ch 23: Synthesis and Characterization of a Coordination Compound
- **Ch 24:** Quaternary Structure in Proteins

Go Figure

Go Figure questions encourage students to stop and analyze the artwork in the text, for conceptual understanding. "Voice Balloons" in selected figures help students break down and understand the components of the image. These questions are also available in MasteringChemistry*. The number of Go Figure questions in the thirteenth edition has increased by 25%.

Practice Exercises

A major new feature of this edition is the addition of a second Practice Exercise to accompany each Sample Exercise within the chapters. The new Practice Exercises are multiple-choice with correct answers provided for the students in an appendix. Specific wrong answer feedback, written by the authors, will be available in MasteringChemistry* The primary goal of the new Practice Exercise feature is to provide students with an additional problem to test mastery of the concepts in the text and to address the most common conceptual misunderstandings. To ensure the questions touched on the most common student misconceptions, the authors consulted the ACS Chemistry Concept inventory before writing their questions.

SAMPLE EXERCISE 2.6 Relating Empirical and Molecular Formulas

Write the empirical formulas for (a) glucose, a substance also known as either blood sugar or dextrose—molecular formula $C_6H_{12}O_6$; (b) nitrous oxide, a substance used as an anesthetic and commonly called laughing gas—molecular formula N_2O .

SOLUTION

- (a) The subscripts of an empirical formula are the smallest wholenumber ratios. The smallest ratios are obtained by dividing each subscript by the largest common factor, in this case 6. The resultant empirical formula for glucose is CH₂O.
- (b) Because the subscripts in N₂O are already the lowest integral numbers, the empirical formula for nitrous oxide is the same as its molecular formula, N₂O.

Practice Exercise 1

Tetracarbon dioxide is an unstable oxide of carbon with the following molecular structure:

What are the molecular and empirical formulas of this substance? (a) C_2O_2 , CO_2 , (b) C_4O , CO, (c) CO_2 , CO_2 , (d) C_4O_2 , C_2O , (e) C_2O , CO_2 .

Practice Exercise 2

Give the empirical formula for decaborane, whose molecular formula is $B_{10}H_{14}$.

Give It Some Thought (GIST) questions

These informal, sharply-focused exercises allow students the opportunity to gauge whether they are "getting it" as they read the text. The number of GIST questions has increased throughout the text as well as in MasteringChemistry*.

Give It Some Thought

A solution of SO_2 in water contains 0.00023 g of SO_2 per liter of solution. What is the concentration of SO_2 in ppm? In ppb?

Active and Visual

he most effective learning happens when students actively participate and interact with material in order to truly internalize key concepts. The Brown/Lemay/Bursten/Murphy/ Woodward/Stoltzfus author team has spent decades refining their text based on educational research to the extent that it has largely defined how the general chemistry course is taught. With the thirteenth edition, these authors have extended this tradition by giving each student a way to personalize their learning experience through MasteringChemistry*. The MasteringChemistry* course for Brown/Lemay/Bursten/Murphy/Woodward/Stoltzfus evolves learning and technology usage far beyond the lecture-homework model. Many of these resources can be used pre-lecture, during class, and for assessment while providing each student with a personalized learning experience which gives them the greatest chance of succeeding.

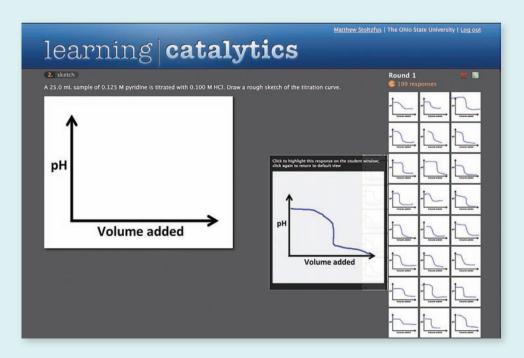

Learning Catalytics

Learning Catalytics™ is a "bring your own device" student engagement, assessment, and classroom intelligence system. With Learning Catalytics™ you can:

- Assess students in real time, using open-ended tasks to probe student understanding.
- Understand immediately where students are and adjust your lecture accordingly.
- · Improve your students' critical-thinking skills.
- Access rich analytics to understand student performance.
- Add your own questions to make Learning Catalytics™ fit your course exactly.
- Manage student interactions with intelligent grouping and timing.

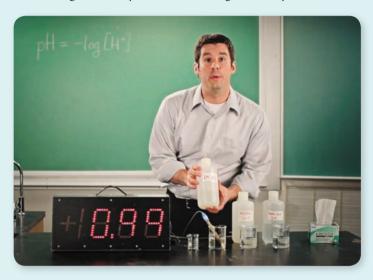

Learning Catalytics[™] is a technology that has grown out of twenty years of cutting-edge research, innovation, and implementation of interactive teaching and peer instruction.

Learning Catalytics™ will be included with the purchase of MasteringChemistry® with eText.

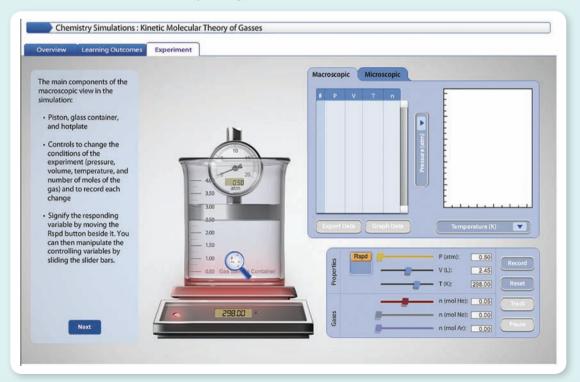

Pause and Predict Videos

Author Dr. Matt Stoltzfus created Pause and Predict Videos. These videos engage students by prompting them to submit a prediction about the outcome of an experiment or demonstration before seeing the final result. A set of assignable tutorials, based on these videos, challenge students to transfer their understanding of the demonstration to related scenarios. These videos are also available in web- and mobile-friendly formats through the study area of MasteringChemistry* and in the Pearson eText.

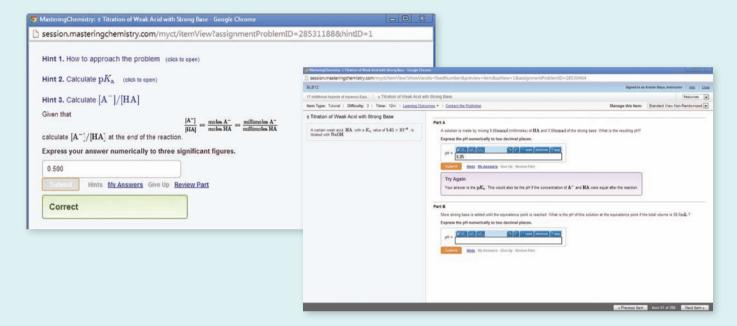

NEW! Simulations, assignable in MasteringChemistry*, include those developed by the PhET Chemistry Group, and the leading authors in simulation development covering some of the most difficult chemistry concepts.

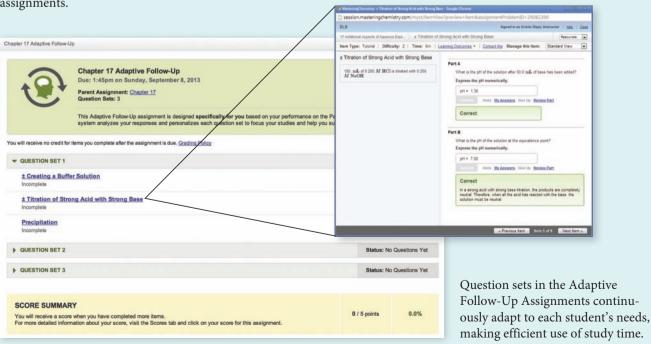

Adaptive

MasteringChemistry* has always been personalized and adaptive on a question level by providing error-specific feedback based on actual student responses; however, Mastering now includes two new adaptive assignment types—Adaptive Follow-Up Assignments and Dynamic Study Modules.

Adaptive Follow-Up Assignments

Instructors have the ability to assign adaptive follow-up assignments. Content delivered to students as part of adaptive learning will be automatically personalized for each individual based on strengths and weaknesses identified by his or her performance on Mastering parent assignments.

Dynamic Study Modules

NEW! Dynamic Study Modules, designed to enable students to study effectively on their own as well as help students quickly access and learn the nomenclature they need to be successful in chemistry.

These modules can be accessed on smartphones, tablets, and computers and results can be tracked in the MasteringChemistry* Gradebook. Here's how it works:

- 1. Students receive an initial set of questions and benefit from the metacognition involved with asking them to indicate how confident they are with their answer.
- **2.** After answering each set of questions, students review their answers.
- **3.** Each question has explanation material that reinforces the correct answer response and addresses the misconceptions found in the wrong answer choices.
- **4.** Once students review the explanations, they are presented with a new set of questions. Students cycle through this dynamic process of test-learn-retest until they achieve mastery of the material.

Introduction: Matter and Measurement

In the title of this book we refer to chemistry as the *central science*. This title reflects the fact that much of what goes on in the world around us involves chemistry. The changes that produce the brilliant colors of tree leaves in the fall, the electrical energy that powers a cell phone, the spoilage of foods left standing at room temperature, and the many ways in which our bodies use the foods we consume are all everyday examples of chemical processes.

Chemistry is the study of matter and the changes that matter undergoes. As you progress in your study, you will come to see how chemical principles operate in all aspects of our lives, from everyday activities like food preparation to more complex processes such as those that operate in the environment. We use chemical principles to understand a host of phenomena, from the role of salt in our diet to the workings of a lithium ion battery.

This first chapter provides an overview of what chemistry is about and what chemists do. The "What's Ahead" list gives an overview of the chapter organization and of some of the ideas we will consider.

1.1 | The Study of Chemistry

Chemistry is at the heart of many changes we see in the world around us, and it accounts for the myriad of different properties we see in matter. To understand how these changes and properties arise, we need to look far beneath the surfaces of our everyday observations.

▶ THE BEAUTIFUL COLORS that develop in trees in the fall appear when the tree ceases to produce chlorophyll, which imparts the green color to the leaves during the summer. Some of the color we see has been in the leaf all summer, and some develops from the action of sunlight on the leaf as the chlorophyll disappears.

- **1.1 THE STUDY OF CHEMISTRY** We begin with a brief description of what chemistry is, what chemists do, and why it is useful to learn chemistry.
- **1.2 CLASSIFICATIONS OF MATTER** Next, we examine some fundamental ways to classify matter, distinguishing between *pure substances* and *mixtures* and between *elements* and *compounds*.
- **1.3 PROPERTIES OF MATTER** We then consider different characteristics, or *properties*, used to characterize, identify, and separate substances, distinguishing between chemical and physical properties.
- **1.4 UNITS OF MEASUREMENT** We observe that many properties rely on quantitative measurements involving numbers and units. The units of measurement used throughout science are those of the *metric system*.

1.5 UNCERTAINTY IN MEASUREMENT We observe that the uncertainty inherent in all measured quantities is expressed by the number of *significant figures* used to report the quantity. Significant figures are also used to express the uncertainty associated with calculations involving measured quantities.

1.6 DIMENSIONAL ANALYSIS We recognize that units as well as numbers are carried through calculations and that obtaining correct units for the result of a calculation is an important way to check whether the calculation is correct.

The Atomic and Molecular Perspective of Chemistry

Chemistry is the study of the properties and behavior of matter. **Matter** is the physical material of the universe; it is anything that has mass and occupies space. A **property** is any characteristic that allows us to recognize a particular type of matter and to distinguish it from other types. This book, your body, the air you are breathing, and the clothes you are wearing are all samples of matter. We observe a tremendous variety of matter in our world, but countless experiments have shown that all matter is comprised of combinations of only about 100 substances called **elements**. One of our major goals will be to relate the properties of matter to its composition, that is, to the particular elements it contains.

Chemistry also provides a background for understanding the properties of matter in terms of **atoms**, the almost infinitesimally small building blocks of matter. Each element is composed of a unique kind of atom. We will see that the properties of matter relate to both the kinds of atoms the matter contains (*composition*) and the arrangements of these atoms (*structure*).

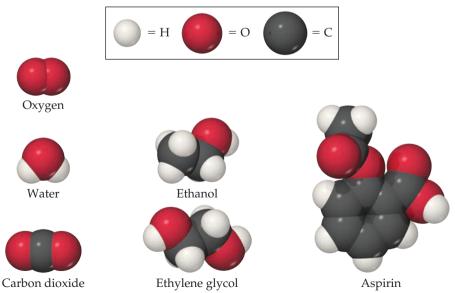

In **molecules**, two or more atoms are joined in specific shapes. Throughout this text you will see molecules represented using colored spheres to show how the atoms are connected (▼ Figure 1.1). The color provides a convenient way to distinguish between atoms of different elements. For example, notice that the molecules of ethanol and ethylene glycol in Figure 1.1 have different compositions and structures. Ethanol contains one oxygen atom, depicted by one red sphere. In contrast, ethylene glycol contains two oxygen atoms.

Even apparently minor differences in the composition or structure of molecules can cause profound differences in properties. For example, let's compare ethanol and ethylene glycol, which appear in Figure 1.1 to be quite similar. Ethanol is the alcohol in beverages such as beer and wine, whereas ethylene glycol is a viscous liquid used as automobile antifreeze. The properties of these two substances differ in many ways, as do their biological activities. Ethanol is consumed throughout the world, but you should *never* consume ethylene glycol because it is highly toxic. One of the challenges chemists undertake is to alter the composition or structure of molecules in a controlled way, creating new substances with different properties. For example, the common drug aspirin, shown in Figure 1.1, was first synthesized in 1897 in a successful attempt to improve on a natural product extracted from willow bark that had long been used to alleviate pain.

Every change in the observable world—from boiling water to the changes that occur as our bodies combat invading viruses—has its basis in the world of atoms and molecules.

Which of the molecules in the figure has the most carbon atoms? How many are there in that molecule?

▲ Figure 1.1 Molecular models. The white, black, and red spheres represent atoms of hydrogen, carbon, and oxygen, respectively.

Thus, as we proceed with our study of chemistry, we will find ourselves thinking in two realms: the *macroscopic* realm of ordinary-sized objects (*macro* = large) and the *submicroscopic* realm of atoms and molecules. We make our observations in the macroscopic world, but to understand that world, we must visualize how atoms and molecules behave at the submicroscopic level. Chemistry is the science that seeks to understand the properties and behavior of matter by studying the properties and behavior of atoms and molecules.

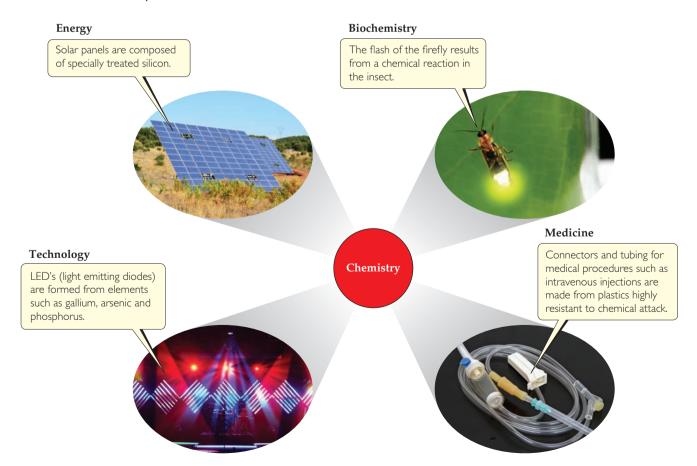

Give It Some Thought

- (a) Approximately how many elements are there?
- (b) What submicroscopic particles are the building blocks of matter?

Why Study Chemistry?

Chemistry lies near the heart of many matters of public concern, such as improvement of health care, conservation of natural resources, protection of the environment, and the supply of energy needed to keep society running. Using chemistry, we have discovered and continually improved upon pharmaceuticals, fertilizers and pesticides, plastics, solar panels, LEDs, and building materials. We have also discovered that some chemicals are potentially harmful to our health or the environment. This means that we must be sure that the materials with which we come into contact are safe. As a citizen and consumer, it is in your best interest to understand the effects, both positive and negative, that chemicals can have, and to arrive at a balanced outlook regarding their uses.

You may be studying chemistry because it is an essential part of your curriculum. Your major might be chemistry, or it could be biology, engineering, pharmacy, agriculture, geology, or some other field. Chemistry is central to a fundamental understanding of governing principles in many science-related fields. For example, our interactions with the material world raise basic questions about the materials around us. ▼ Figure 1.2 illustrates how chemistry is central to several different realms of modern life.

▲ Figure 1.2 Chemistry is central to our understanding of the world around us.

Chemistry Put to Work

Chemistry and the Chemical Industry

Chemistry is all around us. Many people are familiar with household chemicals, particularly kitchen chemicals such as those shown in Figure 1.3. However, few realize the size and importance of the chemical industry. Worldwide sales of chemicals and related products manufactured in the United States total approximately \$585 billion annually. Sales of pharmaceuticals total another \$180 billion. The chemical industry employs more than 10% of all scientists and engineers and is a major contributor to the U.S. economy.

Vast amounts of industrial chemicals are produced each year. ▼ Table 1.1 lists several of the chemicals produced in highest volumes in the United States. Notice that they all serve as raw materials for a variety of uses, including the manufacture and processing of metals, plastics, fertilizers, and other goods.

Who are chemists, and what do they do? People who have degrees in chemistry hold a variety of positions in industry, government, and academia. Those in industry work as laboratory chemists, developing new products (research and development); analyzing materials (quality control); or assisting customers in using products (sales and service). Those with more experience or training may work as managers or company directors. Chemists are important members of the scientific workforce in government (the National Institutes of Health, Department of Energy, and Environmental Protection Agency all employ chemists) and at universities. A chemistry degree is also good preparation for careers in teaching, medicine, biomedical research, information science, environmental work, technical sales, government regulatory agencies, and patent law.

Fundamentally, chemists do three things: (1) make new types of matter: materials, substances, or combinations of substances with

desired properties; (2) measure the properties of matter; and (3) develop models that explain and/or predict the properties of matter. One chemist, for example, may work in the laboratory to discover new drugs. Another may concentrate on the development of new instrumentation to measure properties of matter at the atomic level. Other chemists may use existing materials and methods to understand how pollutants are transported in the environment or how drugs are processed in the body. Yet another chemist will develop theory, write computer code, and run computer simulations to understand how molecules move and react. The collective chemical enterprise is a rich mix of all of these activities.

1.2 | Classifications of Matter

Let's begin our study of chemistry by examining two fundamental ways in which matter is classified. Matter is typically characterized by (1) its physical state (gas, liquid, or solid) and (2) its composition (whether it is an element, a *compound*, or a *mixture*).

^{*}Data from Chemical & Engineering News, July 2, 2007, pp. 57, 60, American Chemical Society; data online from U.S. Geological Survey.

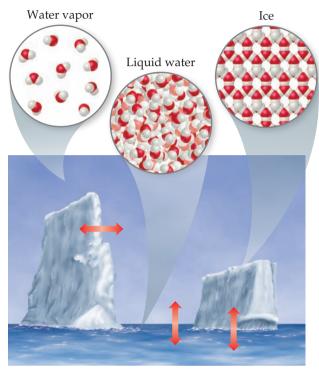

States of Matter

A sample of matter can be a gas, a liquid, or a solid. These three forms, called the **states of matter**, differ in some of their observable properties. A **gas** (also known as *vapor*) has no fixed volume or shape; rather, it uniformly fills its container. A gas can be compressed to occupy a smaller volume, or it can expand to occupy a larger one. A **liquid** has a distinct volume independent of its container, and assumes the shape of the portion of the container it occupies. A **solid** has both a definite shape and a definite volume. Neither liquids nor solids can be compressed to any appreciable extent.

The properties of the states of matter can be understood on the molecular level (> Figure 1.4). In a gas the molecules are far apart and moving at high speeds, colliding repeatedly with one another and with the walls of the container. Compressing a gas decreases the amount of space between molecules and increases the frequency of collisions between molecules but does not alter the size or shape of the molecules. In a liquid, the molecules are packed closely together but still move rapidly. The rapid movement allows the molecules to slide over one another; thus, a liquid pours easily. In a solid the molecules are held tightly together, usually in definite arrangements in which the molecules can wiggle only slightly in their otherwise fixed positions. Thus, the distances between molecules are similar in the liquid and solid states, but the two states differ in how free the molecules are to move around. Changes in temperature and/or pressure can lead to conversion from one state of matter to another, illustrated by such familiar processes as ice melting or water vapor condensing.

▲ GO FIGURE

In which form of water are the water molecules farthest apart?

▲ Figure 1.4 The three physical states of water—water vapor, liquid water, and ice. We see the liquid and solid states but cannot see the gas (vapor) state. The red arrows show that the three states of matter interconvert.

Pure Substances

Most forms of matter we encounter—the air we breathe (a gas), the gasoline we burn in our cars (a liquid), and the sidewalk we walk on (a solid)—are not chemically pure. We can, however, separate these forms of matter into pure substances. A **pure substance** (usually referred to simply as a *substance*) is matter that has distinct properties and a composition that does not vary from sample to sample. Water and table salt (sodium chloride) are examples of pure substances.

All substances are either elements or compounds. **Elements** are substances that cannot be decomposed into simpler substances. On the molecular level, each element is composed of only one kind of atom [**Figure 1.5(a** and **b)**]. **Compounds** are substances composed of two or more elements; they contain two or more kinds of atoms [Figure 1.5(c)]. Water, for example, is a compound composed of two elements: hydrogen and oxygen. Figure 1.5(d) shows a mixture of substances. **Mixtures** are combinations of two or more substances in which each substance retains its chemical identity.

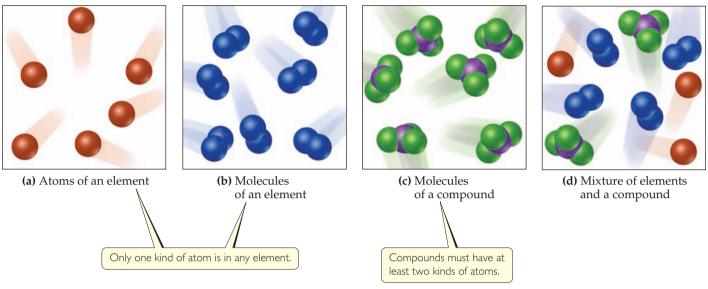

Elements

Currently, 118 elements are known, though they vary widely in abundance. Hydrogen constitutes about 74% of the mass in the Milky Way galaxy, and helium constitutes 24%. Closer to home, only five elements—oxygen, silicon, aluminum, iron, and calcium—account for over 90% of Earth's crust (including oceans and atmosphere), and only three—oxygen, carbon, and hydrogen—account for over 90% of the mass of the human body (Figure 1.6).

GO FIGURE

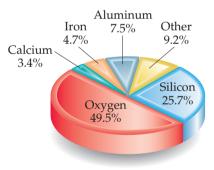

How do the molecules of a compound differ from the molecules of an element?

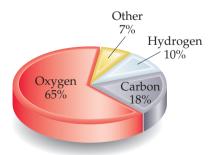

▲ Figure 1.5 Molecular comparison of elements, compounds, and mixtures.

GO FIGURE

Name two significant differences between the elemental composition of Earth's crust and the elemental composition of the human body.

Earth's crust

Human body

▲ Figure 1.6 Relative abundances of elements.* Elements in percent by mass in Earth's crust (including oceans and atmosphere) and the human body.

▼ Table 1.2 lists some common elements, along with the chemical *symbols* used to denote them. The symbol for each element consists of one or two letters, with the first letter capitalized. These symbols are derived mostly from the English names of the elements, but sometimes they are derived from a foreign name instead (last column in Table 1.2). You will need to know these symbols and learn others as we encounter them in the text.

All of the known elements and their symbols are listed on the front inside cover of this text in a table known as the periodic table. In the periodic table the elements are arranged in columns so that closely related elements are grouped together. We describe the periodic table in more detail in Section 2.5 and consider the periodically repeating properties of the elements in Chapter 7.

Compounds

Most elements can interact with other elements to form compounds. For example, when hydrogen gas burns in oxygen gas, the elements hydrogen and oxygen combine to form the compound water. Conversely, water can be decomposed into its elements by passing an electrical current through it (> Figure 1.7).

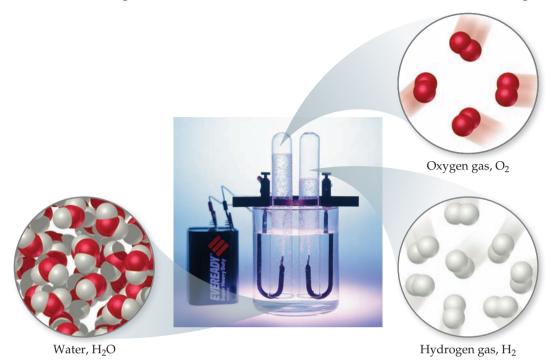

Table 1.2 Some Common Elements and Their Symbols

Carbon	С	Aluminum	Al	Copper	Cu (from cuprum)
Fluorine	F	Bromine	Br	Iron	Fe (from ferrum)
Hydrogen	Н	Calcium	Ca	Lead	Pb (from <i>plumbum</i>)
Iodine	I	Chlorine	Cl	Mercury	Hg (from hydrargyrum)
Nitrogen	N	Helium	He	Potassium	K (from kalium)
Oxygen	Ο	Lithium	Li	Silver	Ag (from argentum)
Phosphorus	P	Magnesium	Mg	Sodium	Na (from natrium)
Sulfur	S	Silicon	Si	Tin	Sn (from stannum)

^{*}U.S. Geological Survey Circular 285, U.S Department of the Interior.

▲ GO FIGURE

How are the relative gas volumes collected in the two tubes related to the relative number of gas molecules in the tubes?

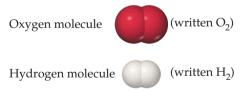

▲ Figure 1.7 Electrolysis of water. Water decomposes into its component elements, hydrogen and oxygen, when an electrical current is passed through it. The volume of hydrogen, collected in the right test tube, is twice the volume of oxygen.

Pure water, regardless of its source, consists of 11% hydrogen and 89% oxygen by mass. This macroscopic composition corresponds to the molecular composition, which consists of two hydrogen atoms combined with one oxygen atom:

The elements hydrogen and oxygen themselves exist naturally as diatomic (two-atom) molecules:

As seen in **▼ Table 1.3**, the properties of water bear no resemblance to the properties of its component elements. Hydrogen, oxygen, and water are each a unique substance, a consequence of the uniqueness of their respective molecules.

Table 1.3 Comparison of Water, Hydrogen, and Oxygen Water Hydrogen Oxygen State^a Liquid Gas Gas Normal boiling point 100 °C −253 °C -183 °C Density^a 1000 g/L 0.084 g/L 1.33 g/L Flammable Yes No

^aAt room temperature and atmospheric pressure.

The observation that the elemental composition of a compound is always the same is known as the **law of constant composition** (or the **law of definite proportions**). French chemist Joseph Louis Proust (1754–1826) first stated the law in about 1800. Although this law has been known for 200 years, the belief persists among some people that a fundamental difference exists between compounds prepared in the laboratory and the corresponding compounds found in nature. However, a pure compound has the same composition and properties under the same conditions regardless of its source. Both chemists and nature must use the same elements and operate under the same natural laws. When two materials differ in composition or properties, either they are composed of different compounds or they differ in purity.

Give It Some Thought

Hydrogen, oxygen, and water are all composed of molecules. What is it about a molecule of water that makes it a compound, whereas hydrogen and oxygen are elements?

Mixtures

Most of the matter we encounter consists of mixtures of different substances. Each substance in a mixture retains its chemical identity and properties. In contrast to a pure substance, which by definition has a fixed composition, the composition of a mixture can vary. A cup of sweetened coffee, for example, can contain either a little sugar or a lot. The substances making up a mixture are called *components* of the mixture.

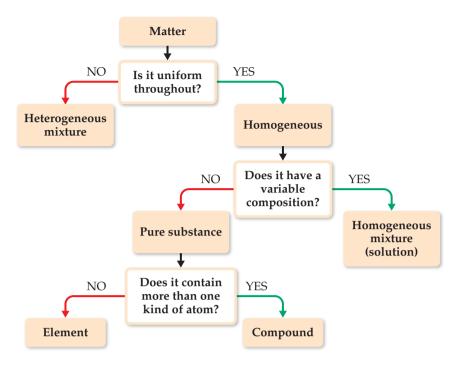

Some mixtures do not have the same composition, properties, and appearance throughout. Rocks and wood, for example, vary in texture and appearance in any typical sample. Such mixtures are *heterogeneous* [**v** Figure 1.8(a)]. Mixtures that are uniform throughout are *homogeneous*. Air is a homogeneous mixture of nitrogen, oxygen, and smaller amounts of other gases. The nitrogen in air has all the properties of pure nitrogen because both the pure substance and the mixture contain the same nitrogen molecules. Salt, sugar, and many other substances dissolve in water to form homogeneous mixtures [Figure 1.8(b)]. Homogeneous mixtures are also called **solutions**. Although the term *solution* conjures an image of a liquid, solutions can be solids, liquids, or gases.

▶ Figure 1.9 summarizes the classification of matter into elements, compounds, and mixtures.

▲ Figure 1.8 Mixtures. (a) Many common materials, including rocks, are heterogeneous mixtures. This photograph of granite shows a heterogeneous mixture of silicon dioxide and other metal oxides. (b) Homogeneous mixtures are called solutions. Many substances, including the blue solid shown here [copper(II) sulfate], dissolve in water to form solutions.

▲ Figure 1.9 Classification of matter. All pure matter is classified ultimately as either an element or a compound.

SAMPLE EXERCISE 1.1 Distinguishing among Elements, Compounds, and Mixtures

"White gold" contains gold and a "white" metal, such as palladium. Two samples of white gold differ in the relative amounts of gold and palladium they contain. Both samples are uniform in composition throughout. Use Figure 1.9 to classify white gold.

SOLUTION

Because the material is uniform throughout, it is homogeneous. Because its composition differs for the two samples, it cannot be a compound. Instead, it must be a homogeneous mixture.

Practice Exercise 1

Which of the following is the correct description of a cube of material cut from the inside of an apple?

- (a) It is a pure compound.
- (b) It consists of a homogenous mixture of compounds.

- (c) It consists of a heterogeneous mixture of compounds.
- (d) It consists of a heterogeneous mixture of elements and compounds.
- (e) It consists of a single compound in different states.

Practice Exercise 2

Aspirin is composed of 60.0% carbon, 4.5% hydrogen, and 35.5% oxygen by mass, regardless of its source. Use Figure 1.9 to classify aspirin.

1.3 | Properties of Matter

Every substance has unique properties. For example, the properties listed in Table 1.3 allow us to distinguish hydrogen, oxygen, and water from one another. The properties of matter can be categorized as physical or chemical. **Physical properties** can be observed without changing the identity and composition of the substance. These properties include color, odor, density, melting point, boiling point, and hardness. **Chemical properties** describe the way a substance may change, or *react*, to form other substances. A common chemical property is flammability, the ability of a substance to burn in the presence of oxygen.

Some properties, such as temperature and melting point, are *intensive properties*. **Intensive properties** do not depend on the amount of sample being examined and are particularly useful in chemistry because many intensive properties can be used to *identify* substances. **Extensive properties** depend on the amount of sample, with two examples being mass and volume. Extensive properties relate to the *amount* of substance present.

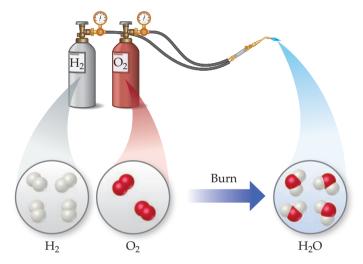

Give It Some Thought

When we say that lead is a denser metal than aluminum, are we talking about an extensive or intensive property?

Physical and Chemical Changes

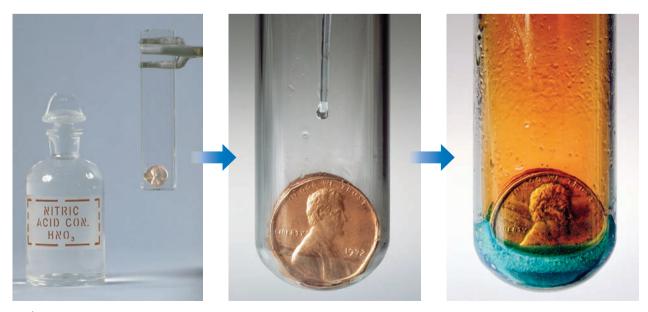

The changes substances undergo are either physical or chemical. During a **physical change**, a substance changes its physical appearance but not its composition. (That is, it is the same substance before and after the change.) The evaporation of water is a physical change. When water evaporates, it changes from the liquid state to the gas state, but it is still composed of water molecules, as depicted in Figure 1.4. All **changes of state** (for example, from liquid to gas or from liquid to solid) are physical changes.

In a **chemical change** (also called a **chemical reaction**), a substance is transformed into a chemically different substance. When hydrogen burns in air, for example, it undergoes a chemical change because it combines with oxygen to form water (**Figure 1.10**).

▲ Figure 1.10 A chemical reaction.

Chemical changes can be dramatic. In the account that follows, Ira Remsen, author of a popular chemistry text published in 1901, describes his first experiences with chemical reactions. The chemical reaction that he observed is shown in ▼ Figure 1.11.

▲ Figure 1.11 The chemical reaction between a copper penny and nitric acid. The dissolved copper produces the blue-green solution; the reddish brown gas produced is nitrogen dioxide.

While reading a textbook of chemistry, I came upon the statement "nitric acid acts upon copper," and I determined to see what this meant. Having located some nitric acid, I had only to learn what the words "act upon" meant. In the interest of knowledge I was even willing to sacrifice one of the few copper cents then in my possession. I put one of them on the table, opened a bottle labeled "nitric acid," poured some of the liquid on the copper, and prepared to make an observation. But what was this wonderful thing which I beheld? The cent was already changed, and it was no small change either. A greenish-blue liquid foamed and fumed over the cent and over the table. The air became colored dark red. How could I stop this? I tried by picking the cent up and throwing it out the window. I learned another fact: nitric acid acts upon fingers. The pain led to another unpremeditated experiment. I drew my fingers across my trousers and discovered nitric acid acts upon trousers. That was the most impressive experiment I have ever performed. I tell of it even now with interest. It was a revelation to me. Plainly the only way to learn about such remarkable kinds of action is to see the results, to experiment, to work in the laboratory.*

Give It Some Thought

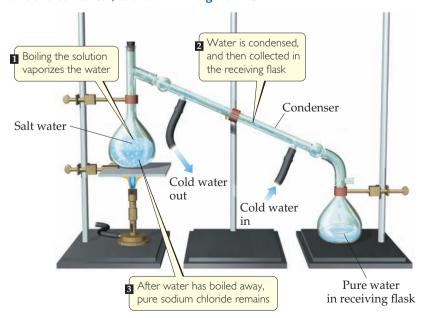

Which of these changes are physical and which are chemical? Explain.

- (a) Plants make sugar from carbon dioxide and water.
- (b) Water vapor in the air forms frost.
- (c) A goldsmith melts a nugget of gold and pulls it into a wire.

Separation of Mixtures

We can separate a mixture into its components by taking advantage of differences in their properties. For example, a heterogeneous mixture of iron filings and gold filings could be sorted by color into iron and gold. A less tedious approach would be to use a magnet to attract the iron filings, leaving the gold ones behind. We can also take advantage of an important chemical difference between these two metals: Many acids dissolve iron but not gold. Thus, if we put our mixture into an appropriate acid, the acid would dissolve the iron and the solid gold would be left behind. The two could then be separated by *filtration* (> Figure 1.12). We would have to use other chemical reactions, which we will learn about later, to transform the dissolved iron back into metal.

An important method of separating the components of a homogeneous mixture is **distillation**, a process that depends on the different abilities of substances to form gases. For example, if we boil a solution of salt and water, the water evaporates, forming a gas, and the salt is left behind. The gaseous water can be converted back to a liquid on the walls of a condenser, as shown in **Figure 1.13**.

▲ Figure 1.13 Distillation. Apparatus for separating a sodium chloride solution (salt water) into its components.

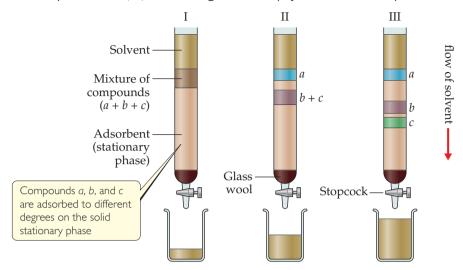

▲ Figure 1.12 Separation by filtration. A mixture of a solid and a liquid is poured through filter paper. The liquid passes through the paper while the solid remains on the paper.

^{*}Remsen, Ira, The Principles of Theoretical Chemistry, 1887.

GO FIGURE

Is the separation of **a**, **b**, and **c** in Figure 1.14 a physical or chemical process?

▲ Figure 1.14 Separation of three substances using column chromatography.

▲ Figure 1.15 Metric units. Metric measurements are increasingly common in the United States, as exemplified by the volume printed on this soda can in both English units (fluid ounces, fl oz) and metric units (milliliters, mL).

The differing abilities of substances to adhere to the surfaces of solids can also be used to separate mixtures. This ability is the basis of *chromatography*, a technique shown in **A Figure 1.14**.

1.4 | Units of Measurement

Many properties of matter are *quantitative*, that is, associated with numbers. When a number represents a measured quantity, the units of that quantity must be specified. To say that the length of a pencil is 17.5 is meaningless. Expressing the number with its units, 17.5 centimeters (cm), properly specifies the length. The units used for scientific measurements are those of the **metric system**.

The metric system, developed in France during the late eighteenth century, is used as the system of measurement in most countries. The United States has traditionally used the English system, although use of the metric system has become more common (Figure 1.15).

A Closer Look

The Scientific Method

Where does scientific knowledge come from? How is it acquired? How do we know it is reliable? How do scientists add to it, or modify it?

There is nothing mysterious about how scientists work. The first idea to keep in mind is that scientific knowledge is gained through observations of the natural world. A principal aim of the scientist is to organize these observations, by identifying patterns and regularity, making measurements, and associating one set of observations with another. The next step is to ask *why* nature behaves in the manner we observe. To answer this question, the scientist constructs a model,

known as a **hypothesis**, to explain the observations. Initially the hypothesis is likely to be pretty tentative. There could be more than one reasonable hypothesis. If a hypothesis is correct, then certain results and observations should follow from it. In this way hypotheses can stimulate the design of experiments to learn more about the system being studied. Scientific creativity comes into play in thinking of hypotheses that are fruitful in suggesting good experiments to do, ones that will shed new light on the nature of the system.

As more information is gathered, the initial hypotheses get winnowed down. Eventually just one may stand out as most consistent with a body of accumulated evidence. We then begin to call this hypothesis a **theory**, a model that has predictive powers, and that accounts for all the available observations. A theory also generally is consistent with other, perhaps larger and more general theories. For example, a theory of what goes on inside a volcano has to be consistent with more general theories regarding heat transfer, chemistry at high temperature, and so forth.

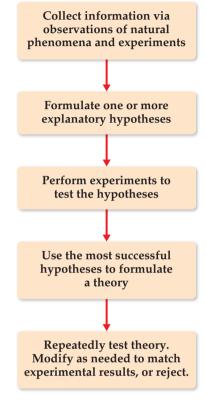

We will be encountering many theories as we proceed through this book. Some of them have been found over and over again to be consistent with observations. However, no theory can be proven to be absolutely true. We can treat it as though it is, but there always remains a possibility that there is some respect in which a theory is wrong. A famous example is Einstein's theory of relativity. Isaac Newton's theory of mechanics yielded such precise results for the mechanical behavior of matter that no exceptions to it were found before the twentieth century. But Albert Einstein showed that Newton's theory of the nature of space and time is incorrect. Einstein's theory of relativity represented a fundamental shift in how we think of space and time. He predicted where the exceptions to predictions based on Newton's theory might be found. Although only small departures from Newton's theory were predicted, they were observed. Einstein's theory of relativity became accepted as the correct model. However, for most uses, Newton's laws of motion are quite accurate enough.

The overall process we have just considered, illustrated in Figure 1.16, is often referred to as the scientific method. But there is no single scientific method. Many factors play a role in advancing scientific knowledge. The one unvarying requirement is that our explanations be consistent with observations, and that they depend solely on natural phenomena.

When nature behaves in a certain way over and over again, under all sorts of different conditions, we can summarize that behavior in a **scientific law**. For example, it has been repeatedly observed that in a chemical reaction there is no change in the total mass of the materials reacting as compared with the materials that are formed; we call this observation the *Law of Conservation of Mass*. It is important to make a distinction between a theory and a scientific law. The latter simply is a statement of what always

happens, to the best of our knowledge. A theory, on the other hand, is an *explanation* for what happens. If we discover some law fails to hold true, then we must assume the theory underlying that law is wrong in some way.

SI Units

In 1960 an international agreement was reached specifying a particular choice of metric units for use in scientific measurements. These preferred units are called **SI units**, after the French *Système International d'Unités*. This system has seven *base units* from which all other units are derived (**Table 1.4**). In this chapter we will consider the base units for length, mass, and temperature.

Table 1.4 SI Base Units	Table 1.4 SI Base Units				
Physical Quantity	Name of Unit	Abbreviation			
Mass	Kilogram	kg			
Length	Meter	m			
Time	Second	s or sec			
Temperature	Kelvin	K			
Amount of substance	Mole	mol			
Electric current	Ampere	A or amp			
Luminous intensity	Candela	cd			

Give It Some Thought

The package of a fluorescent bulb for a table lamp lists the light output in terms of lumens, Im. Which of the seven SI units would you expect to be part of the definition of a lumen?

With SI units, prefixes are used to indicate decimal fractions or multiples of various units. For example, the prefix *milli*-represents a 10^{-3} fraction, one-thousandth, of a unit: A milligram (mg) is 10^{-3} gram (g), a millimeter (mm) is 10^{-3} meter (m), and so forth. ▼ Table 1.5 presents the prefixes commonly encountered in chemistry. In using SI units and in working problems throughout this text, you must be comfortable using exponential notation. If you are unfamiliar with exponential notation or want to review it, refer to Appendix A.1.

Although non-SI units are being phased out, some are still commonly used by scientists. Whenever we first encounter a non-SI unit in the text, the SI unit will also be given. The relations between the non-SI and SI units we will use most frequently in this text appear on the back inside cover. We will discuss how to convert from one to the other in Section 1.6.

Table 1.5	Prefixes Used	l in the Metr	ic System and	l with SI Units

Prefix	Abbreviation	Meaning	Example	
Peta	P	10^{15}	1 petawatt (PW)	$= 1 \times 10^{15} \text{watts}^{\text{a}}$
Tera	T	10^{12}	1 terawatt (TW)	$= 1 \times 10^{12} \text{watts}$
Giga	G	10^{9}	1 gigawatt (GW)	$= 1 \times 10^9 \text{watts}$
Mega	M	10^{6}	1 megawatt (MW)	$= 1 \times 10^6 \text{watts}$
Kilo	k	10^3	1 kilowatt (kW)	$= 1 \times 10^3$ watts
Deci	d	10^{-1}	1 deciwatt (dW)	$= 1 \times 10^{-1} \text{watt}$
Centi	c	10^{-2}	1 centiwatt (cW)	$= 1 \times 10^{-2}$ watt
Milli	m	10^{-3}	1 milliwatt (mW)	$= 1 \times 10^{-3}$ watt
Micro	$\mu^{ m b}$	10^{-6}	1 microwatt (μW)	$= 1 \times 10^{-6}$ watt
Nano	n	10^{-9}	1 nanowatt (nW)	$= 1 \times 10^{-9}$ watt
Pico	p	10^{-12}	1 picowatt (pW)	$= 1 \times 10^{-12} \text{watt}$
Femto	f	10^{-15}	1 femtowatt (fW)	$= 1 \times 10^{-15} \text{watt}$
Atto	a	10^{-18}	1 attowatt (aW)	$= 1 \times 10^{-18} \text{watt}$
Zepto	Z	10^{-21}	1 zeptowatt (zW)	$= 1 \times 10^{-21} \text{watt}$

^aThe watt (W) is the SI unit of power, which is the rate at which energy is either generated or consumed. The SI unit of energy is the joule (J); $1 J = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$ and 1 W = 1 J/s. ^bGreek letter mu, pronounced "mew."

Give It Some Thought

How many μg are there in 1 mg?

Length and Mass

The SI base unit of *length* is the meter, a distance slightly longer than a yard. **Mass*** is a measure of the amount of material in an object. The SI base unit of mass is the kilogram (kg), which is equal to about 2.2 pounds (lb). This base unit is unusual because it uses a prefix, *kilo*-, instead of the word *gram* alone. We obtain other units for mass by adding prefixes to the word *gram*.

SAMPLE EXERCISE 1.2 Using SI Prefixes

What is the name of the unit that equals (a) 10^{-9} gram, (b) 10^{-6} second, (c) 10^{-3} meter?

SOLUTION

We can find the prefix related to each power of ten in Table 1.5: (a) nanogram, ng; (b) microsecond, μs ; (c) millimeter, mm.

Practice Exercise 1

Which of the following weights would you expect to be suitable for weighing on an ordinary bathroom scale?

(a) 2.0×10^7 mg, (b) 2500μ g, (c) 5×10^{-4} kg, (d) 4×10^6 cg, (e) 5.5×10^8 dg.

Practice Exercise 2

(a) How many picometers are there in 1 m? (b) Express 6.0×10^3 m using a prefix to replace the power of ten. (c) Use exponential notation to express 4.22 mg in grams. (d) Use decimal notation to express 4.22 mg in grams.

Temperature

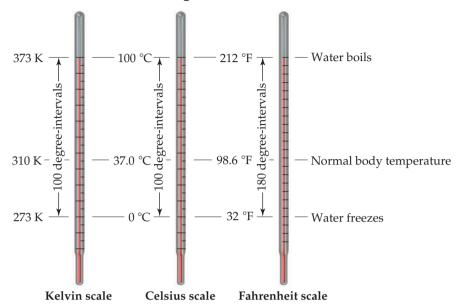

Temperature, a measure of the hotness or coldness of an object, is a physical property that determines the direction of heat flow. Heat always flows spontaneously from a substance at higher temperature to one at lower temperature. Thus, the influx of heat we feel when we touch a hot object tells us that the object is at a higher temperature than our hand.

The temperature scales commonly employed in science are the Celsius and Kelvin scales. The **Celsius scale** was originally based on the assignment of 0 °C to the freezing point of water and 100 °C to its boiling point at sea level (**Figure 1.17**).

^{*}Mass and weight are often incorrectly thought to be the same. The weight of an object is the force that is exerted on its mass by gravity. In space, where gravitational forces are very weak, an astronaut can be weightless, but he or she cannot be massless. The astronaut's mass in space is the same as it is on Earth.

GO FIGURE

True or false: The "size" of a degree on the Celsius scale is the same as the "size" of a degree on the Kelvin scale.

▲ Figure 1.17 Comparison of the Kelvin, Celsius, and Fahrenheit temperature scales.

The **Kelvin scale** is the SI temperature scale, and the SI unit of temperature is the *kelvin* (K). Zero on the Kelvin scale is the lowest attainable temperature, referred to as **absolute zero**. On the Celsius scale, absolute zero has the value, -273.15 °C. The Celsius and Kelvin scales have equal-sized units—that is, a kelvin is the same size as a degree Celsius. Thus, the Kelvin and Celsius scales are related according to

$$K = {}^{\circ}C + 273.15$$
 [1.1]

The freezing point of water, 0 °C, is 273.15 K (Figure 1.17). Notice that we do not use a degree sign (°) with temperatures on the Kelvin scale.

The common temperature scale in the United States is the *Fahrenheit scale*, which is not generally used in science. Water freezes at 32 °F and boils at 212 °F. The Fahrenheit and Celsius scales are related according to

$$^{\circ}C = \frac{5}{9} (^{\circ}F - 32) \text{ or } ^{\circ}F = \frac{9}{5} (^{\circ}C) + 32$$
 [1.2]

SAMPLE

EXERCISE 1.3 Converting Units of Temperature

A weather forecaster predicts the temperature will reach 31 °C. What is this temperature (a) in K, (b) in °F?

SOLUTION

- (a) Using Equation 1.1, we have K = 31 + 273 = 304 K.
- (b) Using Equation 1.2, we have

$$^{\circ}F = \frac{9}{5}(31) + 32 = 56 + 32 = 88 \,^{\circ}F.$$

Practice Exercise 1

Using Wolfram Alpha (http://www.wolframalpha.com/) or some other reference, determine which of these elements would be

liquid at 525 K (assume samples are protected from air): (a) bismuth, Bi; (b) platinum, Pt; (c) selenium, Se; (d) calcium, Ca; (e) copper, Cu.

Practice Exercise 2

Ethylene glycol, the major ingredient in antifreeze, freezes at -11.5 °C. What is the freezing point in (a) K, (b) °F?

Derived SI Units

The SI base units are used to formulate *derived units*. A **derived unit** is obtained by multiplication or division of one or more of the base units. We begin with the defining equation for a quantity and, then substitute the appropriate base units. For example, speed is defined as the ratio of distance traveled to elapsed time. Thus, the SI unit for speed—m/s, read "meters per second"—is a derived unit, the SI unit for distance (length), m, divided by the SI unit for time, s. Two common derived units in chemistry are those for volume and density.

Volume

The *volume* of a cube is its length cubed, length³. Thus, the derived SI unit of volume is the SI unit of length, m, raised to the third power. The cubic meter, m³, is the volume of a cube that is 1 m on each edge (\triangleright Figure 1.18). Smaller units, such as cubic centimeters, cm³ (sometimes written cc), are frequently used in chemistry. Another volume unit used in chemistry is the *liter* (L), which equals a cubic decimeter, dm³, and is slightly larger than a quart. (The liter is the first metric unit we have encountered that is *not* an SI unit.) There are 1000 milliliters (mL) in a liter, and 1 mL is the same volume as 1 cm³: 1 mL = 1 cm³. The devices used most frequently in chemistry to measure volume are illustrated in \blacktriangledown Figure 1.19.

Syringes, burettes, and pipettes deliver amounts of liquids with more precision than graduated cylinders. Volumetric flasks are used to contain specific volumes of liquid.

Give It Some Thought

Which of the following quantities represents volume measurement: 15 m^2 ; $2.5 \times 10^2 \text{ m}^3$; 5.77 L/s? How do you know?

Density

mL 100

▲ GO FIGURE

How many 1-L bottles are required to contain 1 m^3 of liquid?

▲ Figure 1.18 Volume relationships. The volume occupied by a cube 1 m on each edge is one cubic meter, $1 \, \text{m}^3$. Each cubic meter contains $1000 \, \text{dm}^3$. One liter is the same volume as one cubic decimeter, $1 \, \text{L} = 1 \, \text{dm}^3$. Each cubic decimeter contains $1000 \, \text{cubic}$ centimeters, $1 \, \text{dm}^3 = 1000 \, \text{cm}^3$. One cubic centimeter equals one milliliter, $1 \, \text{cm}^3 = 1 \, \text{mL}$.

Table 1.6 Densities of Selected Substances at 25 °C

Substance	Density (g/cm³)
Air	0.001
Balsa wood	0.16
Ethanol	0.79
Water	1.00
Ethylene glycol	1.09
Table sugar	1.59
Table salt	2.16
Iron	7.9
Gold	19.32

The densities of solids and liquids are commonly expressed in either grams per cubic centimeter (g/cm^3) or grams per milliliter (g/mL). The densities of some common substances are listed in \P Table 1.6. It is no coincidence that the density of water is $1.00 \, g/mL$; the gram was originally defined as the mass of 1 mL of water at a specific temperature. Because most substances change volume when they are heated or cooled, densities are temperature dependent, and so temperature should be specified when reporting densities. If no temperature is reported, we assume 25 °C, close to normal room temperature.

The terms *density* and *weight* are sometimes confused. A person who says that iron weighs more than air generally means that iron has a higher density than air—1 kg of air has the same mass as 1 kg of iron, but the iron occupies a smaller volume, thereby giving it a higher density. If we combine two liquids that do not mix, the less dense liquid will float on the denser liquid.

SAMPLE EXERCISE 14

EXERCISE 1.4 Determining Density and Using Density to Determine Volume or Mass

- (a) Calculate the density of mercury if 1.00×10^2 g occupies a volume of 7.36 cm³.
- (b) Calculate the volume of 65.0 g of liquid methanol (wood alcohol) if its density is 0.791 g/mL.
- (c) What is the mass in grams of a cube of gold (density $= 19.32 \, g/cm^3$) if the length of the cube is 2.00 cm?

SOLUTION

(a) We are given mass and volume, so Equation 1.3 yields

Density =
$$\frac{\text{mass}}{\text{volume}} = \frac{1.00 \times 10^2 \,\text{g}}{7.36 \,\text{cm}^3} = 13.6 \,\text{g/cm}^3$$

(b) Solving Equation 1.3 for volume and then using the given mass

and density gives Volume =
$$\frac{\text{mass}}{\text{density}} = \frac{65.0 \text{ g}}{0.791 \text{ g/mL}} = 82.2 \text{ mL}$$

(c) We can calculate the mass from the volume of the cube and its density. The volume of a cube is given by its length cubed:

Volume =
$$(2.00 \text{ cm})^3 = (2.00)^3 \text{ cm}^3 = 8.00 \text{ cm}^3$$

Solving Equation 1.3 for mass and substituting the volume and density of the cube, we have

Mass = volume
$$\times$$
 density = $(8.00 \text{ cm}^3)(19.32 \text{ g/cm}^3) = 155 \text{ g}$

Practice Exercise 1

Platinum, Pt, is one of the rarest of the metals. Worldwide annual production is only about 130 tons. (a) Platinum has a density of 21.4 g/cm^3 . If thieves were to steal platinum from a bank using a small truck with a maximum payload of 900 lb, how many 1 L bars of the metal could they make off with? (a) 19 bars, (b) 2 bars, (c) 42 bars, (d) 1 bar, (e) 47 bars.

Practice Exercise 2

(a) Calculate the density of a 374.5-g sample of copper if it has a volume of $41.8~\text{cm}^3$. (b) A student needs 15.0~g of ethanol for an experiment. If the density of ethanol is 0.789~g/mL, how many milliliters of ethanol are needed? (c) What is the mass, in grams, of 25.0~mL of mercury (density = 13.6~g/mL)?

Chemistry Put to Work

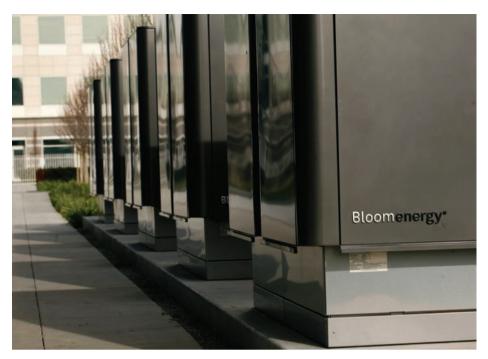

Chemistry in the News

Because chemistry is so central to our lives, reports on matters of chemical significance appear in the news nearly every day. Some reports tell of breakthroughs in the development of new pharmaceuticals, materials, and processes. Others deal with energy, environmental, and public safety issues. As you study chemistry, you will develop the skills to better understand the importance of chemistry in your life. Here are summaries of a few recent stories in which chemistry plays an important role.

Clean energy from fuel cells. In fuel cells, the energy of a chemical reaction is converted directly into electrical energy. Although fuel cells have long been known as potentially valuable sources of electrical energy, their costs have kept them from widespread use. However, recent advances in technology have brought fuel cells to the fore as sources of reliable and clean electrical power in certain critical situations. They are

especially valuable in powering data centers which consume large amounts of electrical power that must be absolutely reliable. For example, failure of electrical power at a major data center for a company such as Amazon, eBay, or Apple could be calamitous for the company and its customers.

eBay recently contracted to build the next phase of its major data center in Utah, utilizing solid–state fuel cells as the source of electrical power. The fuel cells, manufactured by Bloom Energy, a Silicon Valley startup, are large industrial devices about the size of a refrigerator (▶ Figure 1.20). The eBay installation utilizes biogas, which consists of methane and other fuel gases derived from landfills and farms. The fuel is combined with oxygen, and the mixture run through a special solid–state device to produce electricity. Because the electricity is being produced close to the data center, transmission of the electrical power from source to consumption is more efficient. In contrast to electrical backup systems employed in the past, the new power source will be the *primary* source of power, operating

▲ Figure 1.20 Solid-State fuel cells manufactured by Bloom Energy.

24 hours per day, every day of the year. The eBay facility in Utah is the largest nonelectric utility fuel cell installation in the nation. It generates 6 megawatts of power, enough to power about 6000 homes.

Regulation of greenhouse gases. In 2009 the Environmental Protection Agency (EPA) took the position that, under the provisions of the Clean Air Act, it should regulate emissions of "greenhouse" gases. Greenhouse gases are substances that have the potential to alter the global climate because of their ability to trap long-wavelength radiation at Earth's surface. (This subject is covered in detail in Section 18.2.) Greenhouse gases include carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N2O), as well as other substances. The EPA decision was challenged in the courts by several states, industry organizations, and conservative groups. In a major victory for the EPA, the federal court of appeals of the District of Columbia in July 2012 upheld the agency's position. This case is interesting in part because of the grounds on which the EPA policy was challenged, and the way the court responded. The plaintiffs argued that the EPA improperly based its decision on assessments from the Intergovernmental Panel on Climate Change, the U.S. Global Climate Change program, and reports from the National Research Council, rather than on citing the findings of individual research programs in the published literature. The court replied that "it makes no difference that much of the scientific evidence in large part consisted of 'syntheses' of individual studies and research. This is how science works. EPA is not required to re-prove the existence of the atom every time it approaches a scientific question."*

This is an important example of an interaction between science and social policy in our complex, modern society. When other than purely scientific interests are involved, questions about science's reliability and objectivity are bound to arise.

Anesthesia. In the period around the 1840s it became recognized that certain substances, notably ether, chloroform, and nitrous oxide, could induce a state in which the patient had no awareness of bodily pain. You can imagine how joyfully these new discoveries were received by people who had to undergo surgery that would otherwise be unbear-

ably painful. The word *anesthesia* was suggested by Oliver Wendell Holmes, Sr. in 1846 to describe the state in which a person lacks awareness, either total or of a particular part of the body. In time chemists were able to identify certain organic compounds that produced anesthesia without being severely toxic.

More than 40 million patients in North America each year undergo medical procedures that call for anesthesia. The anesthetics used today are most often injected into the blood stream rather than inhaled as a gas. Several organic substances have been identified as effective anesthetics. While modern anesthetics are generally quite safe, they must be administered with care, because they can affect breathing, blood pressure, and heart function. Every drug has a therapeutic index, the ratio of the smallest dose that would be fatal to the smallest dose that gives the desired therapeutic effect. Naturally, one wants the therapeutic index for any drug to be as large as possible. Anesthetics have generally low therapeutic indices, which means that they must be administered carefully and with constant monitoring. The death of the entertainer Mi-

chael Jackson in June 2009 from an overdose of propofol, a widely used anesthetic (▼ Figure 1.21), illustrates how dangerous such drugs can be when not properly administered. Propofol very quickly renders a patient unconscious and affects breathing. Hence its use must be carefully monitored by a person trained in anesthesiology.

Despite a great deal of research, it is still not clear how anesthetics actually work. It is a near-universal characteristic of life that species ranging from tadpoles to humans can be reversibly immobilized. The search for the mechanisms by which this occurs is important, because it may lead us not only to safer anesthetics, but also to deeper understanding of what we mean by *consciousness* itself.

▲ Figure 1.21 Propofol, an anesthetic.

^{*}U.S. Court of Appeals for the District of Columbia , Case No. 09-1322.

GO FIGURE

How would the darts be positioned on the target for the case of "good accuracy, poor precision"?

Good accuracy Good precision

Poor accuracy Good precision

Poor accuracy Poor precision

▲ Figure 1.22 Precision and accuracy.

High precision can be achieved on a scale like this one, which has 0.1 milligram accuracy.

1.5 | Uncertainty in Measurement

Two kinds of numbers are encountered in scientific work: *exact numbers* (those whose values are known exactly) and *inexact numbers* (those whose values have some uncertainty). Most of the exact numbers we will encounter in this book have defined values. For example, there are exactly 12 eggs in a dozen, exactly 1000 g in a kilogram, and exactly 2.54 cm in an inch. The number 1 in any conversion factor, such as 1 m = 100 cm or 1 kg = 2.2046 lb, is an exact number. Exact numbers can also result from counting objects. For example, we can count the exact number of marbles in a jar or the exact number of people in a classroom.

Numbers obtained by measurement are always *inexact*. The equipment used to measure quantities always has inherent limitations (equipment errors), and there are differences in how different people make the same measurement (human errors). Suppose ten students with ten balances are to determine the mass of the same dime. The ten measurements will probably vary slightly for various reasons. The balances might be calibrated slightly differently, and there might be differences in how each student reads the mass from the balance. Remember: *Uncertainties always exist in measured quantities*.

Give It Some Thought

Which of the following is an inexact quantity?

- (a) the number of people in your chemistry class
- (b) the mass of a penny
- (c) the number of grams in a kilogram

Precision and Accuracy

The terms *precision* and *accuracy* are often used in discussing the uncertainties of measured values. **Precision** is a measure of how closely individual measurements agree with one another. **Accuracy** refers to how closely individual measurements agree with the correct, or "true," value. The dart analogy in **◄ Figure 1.22** illustrates the difference between these two concepts.

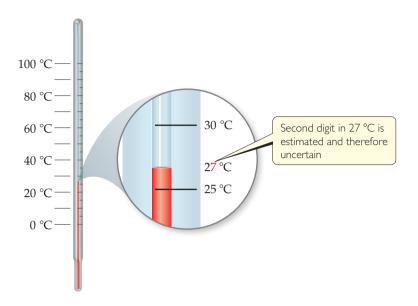

In the laboratory we often perform several "trials" of an experiment and average the results. The precision of the measurements is often expressed in terms of the *standard deviation* (Appendix A.5), which reflects how much the individual measurements differ from the average. We gain confidence in our measurements if we obtain nearly the same value each time—that is, when the standard deviation is small. Figure 1.22 reminds us, however, that precise measurements can be inaccurate. For example, if a very sensitive balance is poorly calibrated, the masses we measure will be consistently either high or low. They will be inaccurate even if they are precise.

Significant Figures

Suppose you determine the mass of a dime on a balance capable of measuring to the nearest 0.0001 g. You could report the mass as 2.2405 \pm 0.0001 g. The \pm notation (read "plus or minus") expresses the magnitude of the uncertainty of your measurement. In much scientific work we drop the \pm notation with the understanding that there is always some uncertainty in the last digit reported for any measured quantity.

▶ Figure 1.23 shows a thermometer with its liquid column between two scale marks. We can read the certain digits from the scale and estimate the uncertain one. Seeing that the liquid is between the 25° and 30 °C marks, we estimate the temperature to be 27 °C, being uncertain of the second digit of our measurement. By *uncertain* we mean that the temperature is reliably 27 °C and not 28° or 26 °C, but we can't say that it is *exactly* 27 °C.

▼ Figure 1.23 Uncertainty and significant figures in a measurement.

All digits of a measured quantity, including the uncertain one, are called **significant figures**. A measured mass reported as 2.2 g has two significant figures, whereas one reported as 2.2405 g has five significant figures. The greater the number of significant figures, the greater the precision implied for the measurement.

SAMPLE EXERCISE 1.5 Relating Significant Figures to the Uncertainty of a Measurement

What difference exists between the measured values 4.0 and 4.00 g?

SOLUTION

The value 4.0 has two significant figures, whereas 4.00 has three. This difference implies that 4.0 has more uncertainty. A mass reported as 4.0 g indicates that the uncertainty is in the first decimal place. Thus, the mass is closer to 4.0 than to 3.9 or 4.1 g. We can represent this uncertainty by writing the mass as 4.0 \pm 0.1 g. A mass reported as 4.00 g indicates that the uncertainty is in the second decimal place. In this case the mass is closer to 4.00 than 3.99 or 4.01 g, and we can represent it as 4.00 \pm 0.01 g. (Without further information, we cannot be sure whether the difference in uncertainties of the two measurements reflects the precision or the accuracy of the measurement.)

Practice Exercise 1

Mo Farah won the 10,000 meter race in the 2012 Olympics with an official time of 27 minutes, 30.42 s. To the correct number of significant figures, what was Farah's average speed in m/sec? (a) 0. 6059 m/s, (b) 1.65042 m/s, (c) 6.059064 m/s, (d) 0.165042 m/s, (e) 6.626192 m/s.

Practice Exercise 2

A sample that has a mass of about 25 g is weighed on a balance that has a precision of ± 0.001 g. How many significant figures should be reported for this measurement?

Give It Some Thought

A digital bathroom scale gives you the following four readings in a row: 155.2, 154.8, 154.9, 154.8 lbs. How would you record your weight?

To determine the number of significant figures in a reported measurement, read the number from left to right, counting the digits starting with the first digit that is not zero. *In any measurement that is properly reported, all nonzero digits are significant.* Because zeros can be used either as part of the measured value or merely to locate the decimal point, they may or may not be significant:

- 1. Zeros between nonzero digits are always significant—1005 kg (four significant figures); 7.03 cm (three significant figures).
- **2.** Zeros *at the beginning* of a number are never significant; they merely indicate the position of the decimal point—0.02 g (one significant figure); 0.0026 cm (two significant figures).

3. Zeros *at the end* of a number are significant if the number contains a decimal point—0.0200 g (three significant figures); 3.0 cm (two significant figures).

A problem arises when a number ends with zeros but contains no decimal point. In such cases, it is normally assumed that the zeros are not significant. Exponential notation (Appendix A.1) can be used to indicate whether end zeros are significant. For example, a mass of 10,300 g can be written to show three, four, or five significant figures depending on how the measurement is obtained:

$1.03 \times 10^4 \mathrm{g}$	(three significant figures)
$1.030\times10^4\mathrm{g}$	(four significant figures)
$1.0300 \times 10^4 \mathrm{g}$	(five significant figures)

In these numbers all the zeros to the right of the decimal point are significant (rules 1 and 3). (The exponential term 10^4 does not add to the number of significant figures.)

SAMPLE EXERCISE 1.6 Assigning Appropriate Significant Figures

The state of Colorado is listed in a road atlas as having a population of 4,301,261 and an area of 104,091 square miles. Do the numbers of significant figures in these two quantities seem reasonable? If not, what seems to be wrong with them?

SOLUTION

The population of Colorado must vary from day to day as people move in or out, are born, or die. Thus, the reported number suggests a much higher degree of *accuracy* than is possible. Secondly, it would not be feasible to actually count every individual resident in the state at any given time. Thus, the reported number suggests far greater *precision* than is possible. A reported number of 4,300,000 would better reflect the actual state of knowledge.

The area of Colorado does not normally vary from time to time, so the question here is whether the accuracy of the measurements is good to six significant figures. It would be possible to achieve such accuracy using satellite technology, provided the legal boundaries are known with sufficient accuracy.

Practice Exercise 1

Which of the following numbers in your personal life are exact numbers?

- (a) Your cell phone number, (b) your weight, (c) your IQ,
- (\boldsymbol{d}) your driver's license number, (\boldsymbol{e}) the distance you walked yesterday.

Practice Exercise 2

The back inside cover of the book tells us that there are 5280 ft in 1 mile. Does this make the mile an exact distance?

SAMPLE EXERCISE 1.7

Determining the Number of Significant Figures in a Measurement

How many significant figures are in each of the following numbers (assume that each number is a measured quantity)? (a) 4.003, (b) 6.023×10^{23} , (c) 5000.

SOLUTION

(a) Four; the zeros are significant figures. (b) Four; the exponential term does not add to the number of significant figures. (c) One; we assume that the zeros are not significant when there is no decimal point shown. If the number has more significant figures, a decimal point should be employed or the number written in exponential notation. Thus, 5000. has four significant figures, whereas 5.00×10^3 has three.

Practice Exercise 1

Sylvia feels as though she may have a fever. Her normal body temperature is $98.7~^\circ F$. She measures her body temperature with a

thermometer placed under her tongue and gets a value of 102.8 °F. How many significant figures are in this measurement?

- (a) Three, the number of degrees to the left of the decimal point;
- (b) four, the number of digits in the measured reading; (c) two, the number of digits in the difference between her current reading and her normal body temperature; (d) three, the number of digits in her normal body temperature; (e) one, the number of digits to the right of the decimal point in the measured value.

Practice Exercise 2

How many significant figures are in each of the following measurements? (a) 3.549 g, (b) 2.3×10^4 cm, (c) 0.00134 m³.

Significant Figures in Calculations

When carrying measured quantities through calculations, the least certain measurement limits the certainty of the calculated quantity and thereby determines the number of significant figures in the final answer. The final answer should be reported with only one uncertain digit. To keep track of significant figures in calculations, we will make frequent use of two rules: one for addition and subtraction, and another for multiplication and division.

1. For addition and subtraction, the result has the same number of decimal places as the measurement with the fewest decimal places. When the result contains more than the correct number of significant figures, it must be rounded off. Consider the following example in which the uncertain digits appear in color:

This number limits	20.42	← two decimal places
the number of significant	1.32 <mark>2</mark>	three decimal places
figures in the result \longrightarrow	83.1	← one decimal place
	104.842	← round off to one decimal place (104.8)

We report the result as 104.8 because 83.1 has only one decimal place.

2. For multiplication and division, the result contains the same number of significant figures as the measurement with the fewest significant figures. When the result contains more than the correct number of significant figures, it must be rounded off. For example, the area of a rectangle whose measured edge lengths are 6.221 and 5.2 cm should be reported with two significant figures, 32 cm², even though a calculator shows the product to have more digits:

Area =
$$(6.221 \text{ cm})(5.2 \text{ cm}) = 32.3492 \text{ cm}^2 \Rightarrow \text{round off to } 32 \text{ cm}^2$$

because 5.2 has two significant figures.

Notice that for addition and subtraction, decimal places are counted in determining how many digits to report in an answer, whereas for multiplication and division, significant figures are counted in determining how many digits to report.

In determining the final answer for a calculated quantity, *exact numbers* are assumed to have an infinite number of significant figures. Thus, when we say, "There are 12 inches in 1 foot," the number 12 is exact, and we need not worry about the number of significant figures in it.

In rounding off numbers, look at the leftmost digit to be removed:

- If the leftmost digit removed is less than 5, the preceding number is left unchanged. Thus, rounding off 7.248 to two significant figures gives 7.2.
- If the leftmost digit removed is 5 or greater, the preceding number is increased by 1. Rounding off 4.735 to three significant figures gives 4.74, and rounding 2.376 to two significant figures gives 2.4.*

Give It Some Thought

A rectangular garden plot is measured to be 25.8 m by 18 m. Which of these dimensions needs to be measured to greater accuracy to provide a more accurate estimate of the area of the plot?

^{*}Your instructor may want you to use a slight variation on the rule when the leftmost digit to be removed is exactly 5, with no following digits or only zeros following. One common practice is to round up to the next higher number if that number will be even and down to the next lower number otherwise. Thus, 4.7350 would be rounded to 4.74, and 4.7450 would also be rounded to 4.74.

SAMPLE EXERCISE 1

EXERCISE 1.8 Determining the Number of Significant Figures in a Calculated Quantity

The width, length, and height of a small box are 15.5, 27.3, and 5.4 cm, respectively. Calculate the volume of the box, using the correct number of significant figures in your answer.

SOLUTION

In reporting the volume, we can show only as many significant figures as given in the dimension with the fewest significant figures, which is that for the height (two significant figures):

Volume = width × length × height
=
$$(15.5 \text{ cm})(27.3 \text{ cm})(5.4 \text{ cm})$$

= $2285.01 \text{ cm}^3 \Rightarrow 2.3 \times 10^3 \text{ cm}^3$

A calculator used for this calculation shows 2285.01, which we must round off to two significant figures. Because the resulting number is 2300, it is best reported in exponential notation, 2.3×10^3 , to clearly indicate two significant figures.

Practice Exercise 1

Ellen recently purchased a new hybrid car and wants to check her gas mileage. At an odometer setting of 651.1 mi, she fills the tank. At 1314.4 mi she requires 16.1 gal to refill the tank. Assuming that the tank is filled to the same level both times, how is the gas mileage best expressed? (a) 40 mi/gal, (b) 41 mi/gal, (c) 41.2 mi/gal, (d) 41.20 mi/gal.

Practice Exercise 2

It takes 10.5 s for a sprinter to run 100.00 m. Calculate her average speed in meters per second and express the result to the correct number of significant figures.

SAMPLE

EXERCISE 1.9 Determining the Number of Significant Figures in a Calculated Quantity

A vessel containing a gas at 25 °C is weighed, emptied, and then reweighed as depicted in

▼ Figure 1.24. From the data provided, calculate the density of the gas at 25 °C.

SOLUTION

To calculate the density, we must know both the mass and the volume of the gas. The mass of the gas is just the difference in the masses of the full and empty container:

$$(837.63 - 836.25) g = 1.38 g$$

In subtracting numbers, we determine the number of significant figures in our result by counting decimal places in each quantity. In this

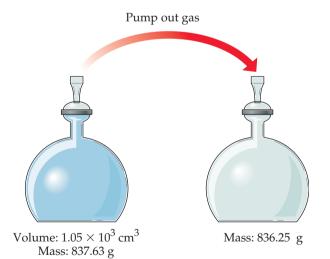

case each quantity has two decimal places. Thus, the mass of the gas, 1.38 g, has two decimal places.

Using the volume given in the question, 1.05 \times $10^3\, cm^3,$ and the definition of density, we have

Density =
$$\frac{\text{mass}}{\text{volume}} = \frac{1.38 \text{ g}}{1.05 \times 10^3 \text{ cm}^3}$$

= $1.31 \times 10^{-3} \text{ g/cm}^3 = 0.00131 \text{ g/cm}^3$

In dividing numbers, we determine the number of significant figures our result should contain by counting the number of significant figures in each quantity. There are three significant figures in our answer, corresponding to the number of significant figures in the two numbers that form the ratio. Notice that in this example, following the rules for determining significant figures gives an answer containing only three significant figures, even though the measured masses contain five significant figures.

▲ Figure 1.24 Uncertainty and significant figures in a measurement.

Practice Exercise 1

Which of the following numbers is correctly rounded to three significant figures, as shown in brackets? (a) 12,556 [12,500], (b) 4.5671×10^{-9} [4.567×10^{-9}], (c) 3.00072 [3.001], (d) 0.006739 [0.00674], (e) 5.4589×10^{5} [5.459×10^{5}].

Practice Exercise 2

If the mass of the container in the sample exercise (Figure 1.24) were measured to three decimal places before and after pumping out the gas, could the density of the gas then be calculated to four significant figures?

When a calculation involves two or more steps and you write answers for intermediate steps, retain at least one nonsignificant digit for the intermediate answers. This procedure ensures that small errors from rounding at each step do not combine to affect the final result. When using a calculator, you may enter the numbers one after another,

rounding only the final answer. Accumulated rounding-off errors may account for small differences among results you obtain and answers given in the text for numerical problems.

1.6 | Dimensional Analysis

Because measured quantities have units associated with them, it is important to keep track of units as well as numerical values when using the quantities in calculations. Throughout the text we use **dimensional analysis** in solving problems. In **dimensional analysis**, units are multiplied together or divided into each other along with the numerical values. Equivalent units cancel each other. Using dimensional analysis helps ensure that solutions to problems yield the proper units. Moreover, it provides a systematic way of solving many numerical problems and of checking solutions for possible errors.

The key to using dimensional analysis is the correct use of *conversion factors* to change one unit into another. A **conversion factor** is a fraction whose numerator and denominator are the same quantity expressed in different units. For example, 2.54 cm and 1 in. are the same length: 2.54 cm = 1 in. This relationship allows us to write two conversion factors:

$$\frac{2.54 \text{ cm}}{1 \text{ in.}}$$
 and $\frac{1 \text{ in.}}{2.54 \text{ cm}}$

We use the first factor to convert inches to centimeters. For example, the length in centimeters of an object that is 8.50 in. long is

Number of centimeters =
$$(8.50 \text{ inc.})$$
 $\frac{2.54 \text{ cm}}{1 \text{ inc.}}$ = 21.6 cm Given unit

The unit inches in the denominator of the conversion factor cancels the unit inches in the given data (8.50 *inches*), so that the centimeters unit in the numerator of the conversion factor becomes the unit of the final answer. Because the numerator and denominator of a conversion factor are equal, multiplying any quantity by a conversion factor is equivalent to multiplying by the number 1 and so does not change the intrinsic value of the quantity. The length 8.50 in. is the same as the length 21.6 cm.

In general, we begin any conversion by examining the units of the given data and the units we desire. We then ask ourselves what conversion factors we have available to take us from the units of the given quantity to those of the desired one. When we multiply a quantity by a conversion factor, the units multiply and divide as follows:

Given unit
$$\times \frac{\text{desired unit}}{\text{given unit}} = \text{desired unit}$$

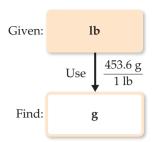

If the desired units are not obtained in a calculation, an error must have been made somewhere. Careful inspection of units often reveals the source of the error.

SAMPLE EXERCISE 1.10 Converting Units

If a woman has a mass of 115 lb, what is her mass in grams? (Use the relationships between units given on the back inside cover of the text.)

SOLUTION

Because we want to change from pounds to grams, we look for a relationship between these units of mass. The conversion factor table found on the back inside cover tells us that 1 lb = 453.6 g.

To cancel pounds and leave grams, we write the conversion factor with grams in the numerator and pounds in the denominator:

Mass in grams =
$$(115 \text{ lb}) \left(\frac{453.6 \text{ g}}{1 \text{ lb}} \right) = 5.22 \times 10^4 \text{ g}$$

The answer can be given to only three significant figures, the number of significant figures in 115 lb. The process we have used is diagrammed in the margin.

Practice Exercise 1

At a particular instant in time the Earth is judged to be 92,955,000 miles from the Sun. What is the distance in kilometers to four significant figures? (See back inside cover for conversion factor). (a) 5763×10^4 km, (b) 1.496×10^8 km, (c) 1.49596×10^8 km, (d) 1.483×10^4 km, (e) 57,759,000 km.

Practice Exercise 2

By using a conversion factor from the back inside cover, determine the length in kilometers of a 500.0-mi automobile race.

Strategies in Chemistry

Estimating Answers

Calculators are wonderful devices; they enable you to get to the wrong answer very quickly. Of course, that's not the destination you want. You can take certain steps to avoid putting that wrong answer into your homework set or on an exam. One is to keep track of the units in a calculation and use the correct conversion factors. Second, you can do a quick mental check to be sure that your answer is reasonable: you can try to make a "ballpark" estimate.

A ballpark estimate involves making a rough calculation using numbers that are rounded off in such a way that the arithmetic can be

done without a calculator. Even though this approach does not give an exact answer, it gives one that is roughly the correct size. By using dimensional analysis and by estimating answers, you can readily check the reasonableness of your calculations.

You can get better at making estimates by practicing in every-day life. How far is it from your dorm room to the chemistry lecture hall? How much do your parents pay for gasoline per year? How many bikes are there on campus? If you respond "I have no idea" to these questions, you're giving up too easily. Try estimating familiar quantities and you'll get better at making estimates in science and in other aspects of your life where a misjudgment can be costly.

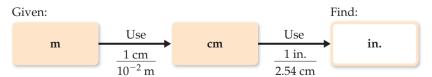

Give It Some Thought

How do we determine how many digits to use in conversion factors, such as the one between pounds and grams in Sample Exercise 1.10?

Using Two or More Conversion Factors

It is often necessary to use several conversion factors in solving a problem. As an example, let's convert the length of an 8.00-m rod to inches. The table on the back inside cover does not give the relationship between meters and inches. It *does*, however, give the relationship between centimeters and inches (1 in. = 2.54 cm). From our knowledge of SI prefixes, we know that 1 cm = 10^{-2} m. Thus, we can convert step by step, first from meters to centimeters and then from centimeters to inches:

Combining the given quantity (8.00 m) and the two conversion factors, we have

Number of inches =
$$(8.00 \text{ m}) \left(\frac{1 \text{ cm}}{10^{-2} \text{ m}} \right) \left(\frac{1 \text{ in.}}{2.54 \text{ cm}} \right) = 315 \text{ in.}$$

The first conversion factor is used to cancel meters and convert the length to centimeters. Thus, meters are written in the denominator and centimeters in the numerator.

The second conversion factor is used to cancel centimeters and convert the length to inches, so it has centimeters in the denominator and inches, the desired unit, in the numerator.

Note that you could have used 100 cm = 1 m as a conversion factor as well in the second parentheses. As long as you keep track of your given units and cancel them properly to obtain the desired units, you are likely to be successful in your calculations.

SAMPLE EXERCISE 1.11 Converting Units Using Two or More Conversion Factors

The average speed of a nitrogen molecule in air at 25 °C is 515 m/s. Convert this speed to miles per hour.

SOLUTION

To go from the given units, m/s, to the desired units, mi/hr, we must convert meters to miles and seconds to hours. From our knowledge of SI prefixes we know that $1 \text{ km} = 10^3 \text{ m}$. From the relationships given on the back inside cover of the book, we find that 1 mi = 1.6093 km.

Thus, we can convert m to km and then convert km to mi. From our knowledge of time we know that 60 s = 1 min and 60 min = 1 hr. Thus, we can convert s to min and then convert min to hr. The overall process is

Applying first the conversions for distance and then those for time, we can set up one long equation in which unwanted units are canceled:

Speed in mi/hr =
$$\left(515\frac{\text{m}}{\text{s}'}\right)\left(\frac{1 \text{ km}}{10^3 \text{ m}'}\right)\left(\frac{1 \text{ mi}}{1.6093 \text{ km}'}\right)\left(\frac{60 \text{ s}'}{1 \text{ min}'}\right)\left(\frac{60 \text{ min}}{1 \text{ hr}}\right)$$

= $1.15 \times 10^3 \text{ mi/hr}$

Our answer has the desired units. We can check our calculation, using the estimating procedure described in the "Strategies in Chemistry" box. The given speed is about 500 m/s. Dividing by 1000 converts m to km, giving 0.5 km/s. Because 1 mi is about 1.6 km, this speed corresponds to 0.5/1.6=0.3 mi/s. Multiplying by 60 gives about $0.3\times60=20$ mi/min. Multiplying again by 60 gives $20\times60=1200$ mi/hr. The approximate solution (about 1200 mi/hr) and the detailed solution (1150 mi/hr) are reasonably close. The answer to the detailed solution has three significant figures, corresponding to the number of significant figures in the given speed in m/s.

Practice Exercise 1

Fabiola, who lives in Mexico City, fills her car with gas, paying 357 pesos for 40.0 L. What is her fuel cost in dollars per gallon, if 1 peso = 0.0759 dollars? (a) \$1.18/gal, (b) \$3.03/gal, (c) \$1.47/gal, (d) \$9.68/gal, (e) \$2.56/gal.

Practice Exercise 2

A car travels 28 mi per gallon of gasoline. What is the mileage in kilometers per liter?

Conversions Involving Volume

The conversion factors previously noted convert from one unit of a given measure to another unit of the same measure, such as from length to length. We also have conversion factors that convert from one measure to a different one. The density of a substance, for example, can be treated as a conversion factor between mass and volume. Suppose we want to know the mass in grams of 2 cubic inches $(2.00 \, \text{in.}^3)$ of gold, which has a density of $19.3 \, \text{g/cm}^3$. The density gives us the conversion factors:

$$\frac{19.3 \text{ g}}{1 \text{ cm}^3}$$
 and $\frac{1 \text{ cm}^3}{19.3 \text{ g}}$

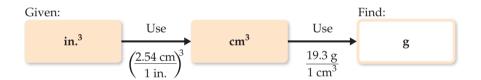

Because we want a mass in grams, we use the first factor, which has mass in grams in the numerator. To use this factor, however, we must first convert cubic inches to cubic centimeters. The relationship between in.³ and cm³ is not given on the back inside cover, but the relationship between inches and centimeters is given: 1 in. = 2.54 cm (exactly). Cubing both sides of this equation gives $(1 \text{ in.})^3 = (2.54 \text{ cm})^3$, from which we write the desired conversion factor:

$$\frac{(2.54 \text{ cm})^3}{(1 \text{ in.})^3} = \frac{(2.54)^3 \text{ cm}^3}{(1)^3 \text{ in.}^3} = \frac{16.39 \text{ cm}^3}{1 \text{ in.}^3}$$

Notice that both the numbers and the units are cubed. Also, because 2.54 is an exact number, we can retain as many digits of $(2.54)^3$ as we need. We have used four, one more than the number of digits in the density (19.3 g/cm^3) . Applying our conversion factors, we can now solve the problem:

Mass in grams =
$$(2.00 \text{ in.}^3) \left(\frac{16.39 \text{ cm}^3}{1 \text{ in.}^3} \right) \left(\frac{19.3 \text{ g}}{1 \text{ cm}^3} \right) = 633 \text{ g}$$

The procedure is diagrammed here. The final answer is reported to three significant figures, the same number of significant figures as in 2.00 in.³ and 19.3 g.

How many liters of water do Earth's oceans contain?

SAMPLE EXERCISE 1.12 Converting Volume Units

Earth's oceans contain approximately 1.36 \times $10^9\,\rm km^3$ of water. Calculate the volume in liters.

SOLUTION

From the back inside cover, we find 1 L = 10^{-3} m³, but there is no relationship listed involving km³. From our knowledge of SI prefixes, however, we know 1 km = 10^{3} m and we can use this relationship between lengths to write the desired conversion factor between volumes:

$$\left(\frac{10^3 \,\mathrm{m}}{1 \,\mathrm{km}}\right)^3 = \frac{10^9 \,\mathrm{m}^3}{1 \,\mathrm{km}^3}$$

Thus, converting from km³ to m³ to L, we have

Volume in liters =
$$(1.36 \times 10^9 \text{ km}^3) \left(\frac{10^9 \text{ m}^3}{1 \text{ km}^3}\right) \left(\frac{1 \text{ L}}{10^{-3} \text{ m}^3}\right) = 1.36 \times 10^{21} \text{ L}$$

Practice Exercise 1

A barrel of oil as measured on the oil market is equal to 1.333 U.S. barrels. A U.S. barrel is equal to 31.5 gal. If oil is on the market at \$94.0 per barrel, what is the price in dollars per gallon? (a) \$2.24/gal, (b) \$3.98/gal, (c) \$2.98/gal, (d) \$1.05/gal, (e) \$8.42/gal.

Practice Exercise 2

The surface area of Earth is 510×10^6 km², and 71% of this is ocean. Using the data from the sample exercise, calculate the average depth of the world's oceans in feet.

Strategies in Chemistry

The Importance of Practice

If you have ever played a musical instrument or participated in athletics, you know that the keys to success are practice and discipline. You cannot learn to play a piano merely by listening to music, and you cannot learn how to play basketball merely by watching games on television. Likewise, you cannot learn chemistry by merely watching your instructor give lectures. Simply reading this book, listening to lectures, or reviewing notes will not usually be sufficient when exam time comes around. Your task is to master chemical concepts and practices to a degree that you can put them to use in solving problems and answering questions. Solving problems correctly takes practice actually, a fair amount of it. You will do well in your chemistry course if you embrace the idea that you need to master the materials presented, and then learn how to apply them in solving problems. Even if you're a brilliant student, this will take time; it's what being a student is all about. Almost no one fully absorbs new material on a first reading, especially when new concepts are being presented. You are sure to more fully master the content of the chapters by reading them through at least twice, even more for passages that present you with difficulties in understanding.

Throughout the book, we have provided sample exercises in which the solutions are shown in detail. For practice exercises, we supply only the answer, at the back of the book. It is important that you use these exercises to test yourself.

The practice exercises in this text and the homework assignments given by your instructor provide the minimal practice that you will need to succeed in your chemistry course. Only by working all the assigned problems will you face the full range of difficulty and coverage that your instructor expects you to master for exams. There is no substitute for a determined and perhaps lengthy effort to work problems on your own. If you are stuck on a problem, however, ask for help from your instructor, a teaching assistant, a tutor, or a fellow student. Spending an inordinate amount of time on a single exercise is rarely effective unless you know that it is particularly challenging and is expected to require extensive thought and effort.

SAMPLE EXERCISE 1.13 Conversions Involving Density

What is the mass in grams of 1.00 gal of water? The density of water is 1.00 g/mL.

SOLUTION

Before we begin solving this exercise, we note the following:

- (1) We are given 1.00 gal of water (the known, or given, quantity) and asked to calculate its mass in grams (the unknown).
- (2) We have the following conversion factors either given, commonly known, or available on the back inside cover of the text:

$$\frac{1.00 \text{ g water}}{1 \text{ mL water}} \quad \frac{1 \text{ L}}{1000 \text{ mL}} \quad \frac{1 \text{ L}}{1.057 \text{ qt}} \quad \frac{1 \text{ gal}}{4 \text{ qt}}$$

The first of these conversion factors must be used as written (with grams in the numerator) to give the desired result, whereas the last conversion factor must be inverted in order to cancel gallons:

$$\begin{split} \text{Mass in grams} &= (1.00 \text{ gaI}) \bigg(\frac{4 \text{ qf}}{1 \text{ gaI}}\bigg) \bigg(\frac{1 \text{ L}}{1.057 \text{ qf}}\bigg) \bigg(\frac{1000 \text{ m/L}}{1 \text{ L}}\bigg) \bigg(\frac{1.000 \text{ g}}{1 \text{ m/L}}\bigg) \\ &= 3.78 \times 10^3 \text{ g water} \end{split}$$

The unit of our final answer is appropriate, and we have taken care of our significant figures. We can further check our calculation by estimating. We can round 1.057 off to 1. Then focusing on the numbers that do not equal 1 gives $4\times1000=4000$ g, in agreement with the detailed calculation.

You should also use common sense to assess the reasonableness of your answer. In this case we know that most people can lift a gallon of milk with one hand, although it would be tiring to carry it around all day. Milk is mostly water and will have a density not too different from that of water. Therefore, we might estimate that a gallon of water has mass that is more than 5 lb but less than 50 lb. The mass we have calculated, 3.78 kg \times 2.2 lb/kg = 8.3 lb, is thus reasonable as an order-of-magnitude estimate.

Practice Exercise 1

Trex is a manufactured substitute for wood compounded from post-consumer plastic and wood. It is frequently used in outdoor decks. Its density is reported as 60 lb/ft^3 . What is the density of Trex in kg/L? (a) 138 kg/L, (b) 0.960 kg/L, (c) 259 kg/L, (d) 15.8 kg/L, (e) 11.5 kg/L.

Practice Exercise 2

The density of the organic compound benzene is 0.879 g/mL. Calculate the mass in grams of 1.00 qt of benzene.

A Trex deck.

Strategies in Chemistry

The Features of This Book

If, like most students, you haven't yet read the part of the Preface to this text entitled TO THE STUDENT, you should do it now. In less than two pages of reading you will encounter valuable advice on how to navigate your way through this book and through the course. We're serious! This is advice you can use.

The TO THE STUDENT section describes how text features such as "What's Ahead," Key Terms, Learning Outcomes, and Key Equations will help you remember what you have learned. We describe there also how to take advantage of the text's Web site, where many types of online study tools are available. If you have registered for MasteringChemistry*, you will have access to many helpful animations, tutorials, and additional problems correlated to specific topics and sections of each chapter. An interactive eBook is also available online.

As previously mentioned, working exercises is very important—in fact, essential. You will find a large variety of exercises at the end of each chapter that are designed to test your problem-solving skills in chemistry. Your instructor will very likely assign some of these end-of-chapter exercises as homework. The first few exercises called

"Visualizing Concepts" are meant to test how well you understand a concept without plugging a lot of numbers into a formula. The other exercises are grouped in pairs, with the answers given at the back of the book to the odd-numbered exercises (those with red exercise numbers). An exercise with a [bracket] around its number is designed to be more challenging. Additional Exercises appear after the regular exercises; the chapter sections that they cover are not identified, and they are not paired. Integrative Exercises, which start appearing from Chapter 3, are problems that require skills learned in previous chapters. Also first appearing in Chapter 3, are Design an Experiment exercises consisting of problem scenarios that challenge you to design experiments to test hypotheses.

Many chemical databases are available, usually on the Web. The *CRC Handbook of Chemistry and Physics* is the standard reference for many types of data and is available in libraries. The *Merck Index* is a standard reference for the properties of many organic compounds, especially ones of biological interest. WebElements (http://www.webelements.com/) is a good Web site for looking up the properties of the elements. Wolfram Alpha (http://www.wolframalpha.com/) can also be a source of useful information on substances, numerical values, and other data.

Chapter Summary and Key Terms

THE STUDY OF CHEMISTRY (SECTION 1.1) Chemistry is the study of the composition, structure, properties, and changes of **matter**. The composition of matter relates to the kinds of **elements** it contains. The structure of matter relates to the ways the **atoms** of these elements are arranged. A **property** is any characteristic that gives a sample of matter its unique identity. A **molecule** is an entity composed of two or more atoms with the atoms attached to one another in a specific way.

CLASSIFICATIONS OF MATTER (SECTION 1.2) Matter exists in three physical states, gas, liquid, and solid, which are known as the states of matter. There are two kinds of pure substances: elements and compounds. Each element has a single kind of atom and is represented by a chemical symbol consisting of one or two letters, with the first letter capitalized. Compounds are composed of two or more elements joined chemically. The law of constant composition, also called the law of definite proportions, states that the elemental composition of a pure compound is always the same. Most matter consists of a mixture of substances. Mixtures have variable compositions and can be either homogeneous or heterogeneous; homogeneous mixtures are called solutions.

PROPERTIES OF MATTER (SECTION 1.3) Each substance has a unique set of physical properties and chemical properties that can be used to identify it. During a physical change, matter does not change its composition. Changes of state are physical changes. In a chemical change (chemical reaction) a substance is transformed into a chemically different substance. Intensive properties are independent of the amount of matter examined and are used to identify substances. Extensive properties relate to the amount of substance present. Differences in physical and chemical properties are used to separate substances.

The **scientific method** is a dynamic process used to answer questions about the physical world. Observations and experiments lead to tentative explanations or **hypotheses**. As a hypothesis is tested and refined, a **theory** may be developed that can predict the results of future observations and experiments. When observations repeatedly lead to

the same consistent results, we speak of a **scientific law**, a general rule that summarizes how nature behaves.

UNITS OF MEASUREMENT (SECTION 1.4) Measurements in chemistry are made using the metric system. Special emphasis is placed on SI units, which are based on the meter, the kilogram, and the second as the basic units of length, mass, and time, respectively. SI units use prefixes to indicate fractions or multiples of base units. The SI temperature scale is the Kelvin scale, although the Celsius scale is frequently used as well. Absolute zero is the lowest temperature attainable. It has the value 0 K. A derived unit is obtained by multiplication or division of SI base units. Derived units are needed for defined quantities such as speed or volume. Density is an important defined quantity that equals mass divided by volume.

UNCERTAINTY IN MEASUREMENT (SECTION 1.5) All measured quantities are inexact to some extent. The **precision** of a measurement indicates how closely different measurements of a quantity agree with one another. The **accuracy** of a measurement indicates how well a measurement agrees with the accepted or "true" value. The **significant figures** in a measured quantity include one estimated digit, the last digit of the measurement. The significant figures indicate the extent of the uncertainty of the measurement. Certain rules must be followed so that a calculation involving measured quantities is reported with the appropriate number of significant figures.

DIMENSIONAL ANALYSIS (SECTION 1.6) In the dimensional analysis approach to problem solving, we keep track of units as we carry measurements through calculations. The units are multiplied together, divided into each other, or canceled like algebraic quantities. Obtaining the proper units for the final result is an important means of checking the method of calculation. When converting units and when carrying out several other types of problems, **conversion factors** can be used. These factors are ratios constructed from valid relations between equivalent quantities.

Learning Outcomes After studying this chapter, you should be able to:

- Distinguish among elements, compounds, and mixtures. (Section 1.2)
- Identify symbols of common elements. (Section 1.2)
- Identify common metric prefixes. (Section 1.4)

- Demonstrate the use of significant figures, scientific notation, and SI units in calculations. (Section 1.5)
- Attach appropriate SI units to defined quantities, and employ dimensional analysis in calculations. (Sections 1.4 and 1.6)

Key Equations

•
$$K = {}^{\circ}C + 273.15$$
 [1.1]

Converting between Celsius (°C) and Kelvin (K) temperature scales

• °C =
$$\frac{5}{9}$$
(°F - 32) or °F = $\frac{9}{5}$ (°C) + 32 [1.2]

Converting between Celsius (°C) and Fahrenheit (°F) temperature scales

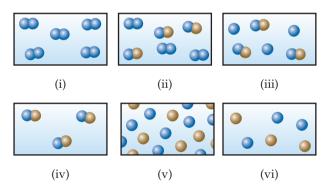

• Density =
$$\frac{\text{mass}}{\text{volume}}$$

Exercises

Visualizing Concepts

1.1 Which of the following figures represents (a) a pure element,(b) a mixture of two elements, (c) a pure compound,(d) a mixture of an element and a compound? (More than one picture might fit each description.) [Section 1.2]

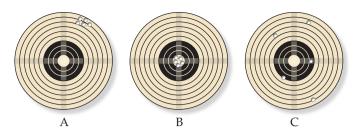

1.2 Does the following diagram represent a chemical or physical change? How do you know? [Section 1.3]

1.3 Describe the separation method(s) involved in brewing a cup of coffee. [Section 1.3]

- **1.4** Identify each of the following as measurements of length, area, volume, mass, density, time, or temperature: **(a)** 25 ps, **(b)** 374.2 mg, **(c)** 77 K, **(d)** 100,000 km², **(e)** 1.06 μ m, **(f)** 16 nm², **(g)** -78 °C, **(h)** 2.56 g/cm³, **(i)** 28 cm³. [Section 1.4]
- 1.5 (a) Three spheres of equal size are composed of aluminum (density = 2.70 g/cm³), silver (density = 10.49 g/cm³), and nickel (density = 8.90 g/cm³). List the spheres from lightest to heaviest. (b) Three cubes of equal mass are composed of gold (density = 19.32 g/cm³), platinum (density = 21.45 g/cm³), and lead (density = 11.35 g/cm³). List the cubes from smallest to largest. [Section 1.4]
- 1.6 The three targets from a rifle range shown on the next page were produced by: (A) the instructor firing a newly acquired target rifle; (B) the instructor firing his personal target rifle; and (C) a student who has fired his target rifle only a few times. (a) Comment on the accuracy and precision for each of these three sets of results. (b) For the A and C results in the future to look like those in B, what needs to happen? [Section 1.5]

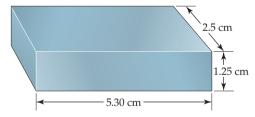

1.7 (a) What is the length of the pencil in the following figure if the ruler reads in centimeters? How many significant figures are there in this measurement? (b) An automobile speedometer with circular scales reading both miles per hour and kilometers per hour is shown. What speed is indicated, in both units? How many significant figures are in the measurements? [Section 1.5]

10000

1.8 (a) How many significant figures should be reported for the volume of the metal bar shown here? (b) If the mass of the bar is 104.72 g, how many significant figures should be reported when its density is determined using the calculated volume? [Section 1.5]

- 1.9 When you convert units, how do you decide which part of the conversion factor is in the numerator and which is in the denominator? [Section 1.6]
- **1.10** Show the steps to convert the speed of sound, 344 meters per second, into miles per hour. [Section 1.6]
- 1.11 Consider the jar of jelly beans in the photo. To get an estimate of the number of beans in the jar you weigh six beans and obtain masses of 3.15, 3.12, 2.98, 3.14, 3.02, and 3.09 g. Then you weigh the jar with all the beans in it, and obtain a mass of 2082 g. The empty jar has a mass of 653 g. Based on these data estimate the number of beans in the jar. Justify the number of significant figures you use in your estimate. [Section 1.5]

1.12 The photo below shows a picture of an agate stone. Jack, who picked up the stone on the Lake Superior shoreline and polished it, insists that agate is a chemical compound. Ellen argues that it cannot be a compound. Discuss the relative merits of their positions. [Section 1.2]

Classification and Properties of Matter (Sections 1.2 and 1.3)

- 1.13 Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: (a) rice pudding, (b) seawater, (c) magnesium, (d) crushed ice.
- 1.14 Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: (a) air, (b) tomato juice, (c) iodine crystals, (d) sand.
- 1.15 Give the chemical symbol or name for the following elements, as appropriate: (a) sulfur, (b) gold, (c) potassium, (d) chlorine, (e) copper, (f) U, (g) Ni, (h) Na, (i) Al, (j) Si.
- 1.16 Give the chemical symbol or name for each of the following elements, as appropriate: (a) carbon, (b) nitrogen,
 (c) titanium, (d) zinc, (e) iron, (f) P, (g) Ca, (h) He,
 (i) Pb, (j) Ag.
- 1.17 A solid white substance A is heated strongly in the absence of air. It decomposes to form a new white substance B and a gas C. The gas has exactly the same properties as the product obtained when carbon is burned in an excess of oxygen. Based on these observations, can we determine whether solids A and B and gas C are elements or compounds? Explain your conclusions for each substance.
- 1.18 You are hiking in the mountains and find a shiny gold nugget. It might be the element gold, or it might be "fool's gold," which is a nickname for iron pyrite, FeS₂. What kinds of experiments could be done to determine if the shiny nugget is really gold?

- 1.19 In the process of attempting to characterize a substance, a chemist makes the following observations: The substance is a silvery white, lustrous metal. It melts at 649 °C and boils at 1105 °C. Its density at 20 °C is 1.738 g/cm³. The substance burns in air, producing an intense white light. It reacts with chlorine to give a brittle white solid. The substance can be pounded into thin sheets or drawn into wires. It is a good conductor of electricity. Which of these characteristics are physical properties, and which are chemical properties?
- **1.20** (a) Read the following description of the element zinc and indicate which are physical properties and which are chemical properties.

Zinc melts at 420 $^{\circ}$ C. When zinc granules are added to dilute sulfuric acid, hydrogen is given off and the metal dissolves. Zinc has a hardness on the Mohs scale of 2.5 and a density of 7.13g/cm^3 at 25 $^{\circ}$ C. It reacts slowly with oxygen gas at elevated temperatures to form zinc oxide, ZnO.

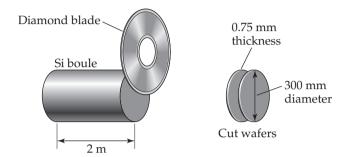

- **(b)** Which properties of zinc can you describe from the photo? Are these physical or chemical properties?
- 1.21 Label each of the following as either a physical process or a chemical process: (a) rusting of a metal can, (b) boiling a cup of water, (c) pulverizing an aspirin, (d) digesting a candy bar, (e) exploding of nitroglyerin.
- 1.22 A match is lit and held under a cold piece of metal. The following observations are made: (a) The match burns.(b) The metal gets warmer. (c) Water condenses on the metal.(d) Soot (carbon) is deposited on the metal. Which of these occurrences are due to physical changes, and which are due to chemical changes?
- **1.23** Suggest a method of separating each of the following mixtures into two components: (a) sugar and sand, (b) oil and vinegar.
- **1.24** Three beakers contain clear, colorless liquids. One beaker contains pure water, another contains salt water, and another contains sugar water. How can you tell which beaker is which? (No tasting allowed!)

Units and Measurement (Section 1.4)

- **1.25** What exponential notation do the following abbreviations represent? (a) d, (b) c, (c) f, (d) μ , (e) M, (f) k, (g) n, (h) m, (i) p.
- **1.26** Use appropriate metric prefixes to write the following measurements without use of exponents: (a) $2.3 \times 10^{-10} \, \text{L}$, (b) $4.7 \times 10^{-6} \, \text{g}$, (c) $1.85 \times 10^{-12} \, \text{m}$, (d) $16.7 \times 10^{6} \, \text{s}$, (e) $15.7 \times 10^{3} \, \text{g}$, (f) $1.34 \times 10^{-3} \, \text{m}$, (g) $1.84 \times 10^{2} \, \text{cm}$.
- 1.27 Make the following conversions: (a) 72 °F to °C, (b) 216.7 °C to °F, (c) 233 °C to K, (d) 315 K to °F, (e) 2500 °F to K, (f) 0 K to °F.

- 1.28 (a) The temperature on a warm summer day is 87 °F. What is the temperature in °C? (b) Many scientific data are reported at 25 °C. What is this temperature in kelvins and in degrees Fahrenheit? (c) Suppose that a recipe calls for an oven temperature of 400 °F. Convert this temperature to degrees Celsius and to kelvins. (d) Liquid nitrogen boils at 77 K. Convert this temperature to degrees Fahrenheit and to degrees Celsius.
- **1.29** (a) A sample of tetrachloroethylene, a liquid used in dry cleaning that is being phased out because of its potential to cause cancer, has a mass of 40.55 g and a volume of 25.0 mL at 25 °C. What is its density at this temperature? Will tetrachloroethylene float on water? (Materials that are less dense than water will float.) (b) Carbon dioxide (CO₂) is a gas at room temperature and pressure. However, carbon dioxide can be put under pressure to become a "supercritical fluid" that is a much safer dry-cleaning agent than tetrachloroethylene. At a certain pressure, the density of supercritical CO₂ is 0.469 g/cm³. What is the mass of a 25.0-mL sample of supercritical CO₂ at this pressure?
- 1.30 (a) A cube of osmium metal 1.500 cm on a side has a mass of 76.31 g at 25 °C. What is its density in g/cm³ at this temperature? (b) The density of titanium metal is 4.51g/cm³ at 25 °C. What mass of titanium displaces 125.0 mL of water at 25 °C? (c) The density of benzene at 15 °C is 0.8787g/mL. Calculate the mass of 0.1500 L of benzene at this temperature.
- 1.31 (a) To identify a liquid substance, a student determined its density. Using a graduated cylinder, she measured out a 45-mL sample of the substance. She then measured the mass of the sample, finding that it weighed 38.5 g. She knew that the substance had to be either isopropyl alcohol (density 0.785 g/mL) or toluene (density 0.866/mL). What are the calculated density and the probable identity of the substance? (b) An experiment requires 45.0 g of ethylene glycol, a liquid whose density is 1.114 g/mL. Rather than weigh the sample on a balance, a chemist chooses to dispense the liquid using a graduated cylinder. What volume of the liquid should he use? (c) Is a graduated cylinder such as that shown in Figure 1.19 likely to afford the accuracy of measurement needed? (d) A cubic piece of metal measures 5.00 cm on each edge. If the metal is nickel, whose density is 8.90 g/cm³, what is the mass of the cube?
- 1.32 (a) After the label fell off a bottle containing a clear liquid believed to be benzene, a chemist measured the density of the liquid to verify its identity. A 25.0-mL portion of the liquid had a mass of 21.95 g. A chemistry handbook lists the density of benzene at 15 °C as 0.8787 g/mL. Is the calculated density in agreement with the tabulated value? (b) An experiment requires 15.0 g of cyclohexane, whose density at 25 °C is 0.7781 g/mL. What volume of cyclohexane should be used? (c) A spherical ball of lead has a diameter of 5.0 cm. What is the mass of the sphere if lead has a density of 11.34 g/cm³? (The volume of a sphere is $(4/3)\pi r^3$, where r is the radius.)
- 1.33 In the year 2011, an estimated amount of 35 billion tons of carbon dioxide (CO₂) was emitted worldwide due to fossil fuel combustion and cement production. Express this mass of CO₂ in grams without exponential notation, using an appropriate metric prefix.

1.34 Silicon for computer chips is grown in large cylinders called "boules" that are 300 mm in diameter and 2 m in length, as shown. The density of silicon is $2.33 \, \mathrm{g/cm^3}$. Silicon wafers for making integrated circuits are sliced from a 2.0 m boule and are typically 0.75 mm thick and 300 mm in diameter. (a) How many wafers can be cut from a single boule? (b) What is the mass of a silicon wafer? (The volume of a cylinder is given by $\pi r^2 h$, where r is the radius and h is its height.)

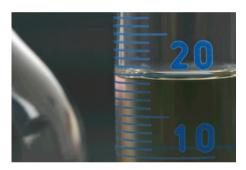

Uncertainty in Measurement (Section 1.5)

- 1.35 Indicate which of the following are exact numbers: (a) the mass of a 3 by 5-inch index card, (b) the number of ounces in a pound, (c) the volume of a cup of Seattle's Best coffee, (d) the number of inches in a mile, (e) the number of microseconds in a week, (f) the number of pages in this book.
- 1.36 Indicate which of the following are exact numbers: (a) the mass of a 32-oz can of coffee, (b) the number of students in your chemistry class, (c) the temperature of the surface of the Sun, (d) the mass of a postage stamp, (e) the number of milliliters in a cubic meter of water, (f) the average height of NBA basketball players.
- 1.37 What is the number of significant figures in each of the following measured quantities? (a) 601 kg, (b) 0.054 s, (c) 6.3050 cm, (d) 0.0105 L, (e) 7.0500×10^{-3} m³, (f) 400 g.
- 1.38 Indicate the number of significant figures in each of the following measured quantities: (a) 3.774 km, (b) 205 m^2 , (c) 1.700 cm, (d) 350.00 K, (e) 307.080 g, (f) $1.3 \times 10^3 \text{ m/s}$.
- **1.39** Round each of the following numbers to four significant figures and express the result in standard exponential notation: **(a)** 102.53070, **(b)** 656.980, **(c)** 0.008543210, **(d)** 0.000257870, **(e)** -0.0357202.
- 1.40 (a) The diameter of Earth at the equator is 7926.381 mi. Round this number to three significant figures and express it in standard exponential notation. (b) The circumference of Earth through the poles is 40,008 km. Round this number to four significant figures and express it in standard exponential notation.
- **1.41** Carry out the following operations and express the answers with the appropriate number of significant figures.
 - (a) 14.3505 + 2.65
 - **(b)** 952.7 140.7389
 - (c) $(3.29 \times 10^4)(0.2501)$
 - (d) 0.0588/0.677
- **1.42** Carry out the following operations and express the answer with the appropriate number of significant figures.

- (a) 320.5 (6104.5/2.3)
- **(b)** $\lceil (285.3 \times 10^5) (1.200 \times 10^3) \rceil \times 2.8954$
- (c) $(0.0045 \times 20,000.0) + (2813 \times 12)$
- (d) $863 \times [1255 (3.45 \times 108)]$
- **1.43** You weigh an object on a balance and read the mass in grams according to the picture. How many significant figures are in this measurement?

1.44 You have a graduated cylinder that contains a liquid (see photograph). Write the volume of the liquid, in milliliters, using the proper number of significant figures.

Dimensional Analysis (Section 1.6)

- 1.45 Using your knowledge of metric units, English units, and the information on the back inside cover, write down the conversion factors needed to convert (a) mm to nm, (b) mg to kg, (c) km to ft, (d) in.3 to cm3.
- **1.46** Using your knowledge of metric units, English units, and the information on the back inside cover, write down the conversion factors needed to convert (a) μ m to mm, (b) ms to ns, (c) mi to km, (d) ft³ to L.
- 1.47 (a) A bumblebee flies with a ground speed of 15.2 m/s. Calculate its speed in km/hr. (b) The lung capacity of the blue whale is 5.0 × 10³ L. Convert this volume into gallons.
 (c) The Statue of Liberty is 151 ft tall. Calculate its height in meters. (d) Bamboo can grow up to 60.0 cm/day. Convert this growth rate into inches per hour.
- 1.48 (a) The speed of light in a vacuum is 2.998 × 10⁸ m/s. Calculate its speed in miles per hour. (b) The Sears Tower in Chicago is 1454 ft tall. Calculate its height in meters. (c) The Vehicle Assembly Building at the Kennedy Space Center in Florida has a volume of 3,666,500 m³. Convert this volume to liters and express the result in standard exponential notation. (d) An individual suffering from a high cholesterol level in her

- blood has 242 mg of cholesterol per 100 mL of blood. If the total blood volume of the individual is 5.2 L, how many grams of total blood cholesterol does the individual's body contain?
- 1.49 The inside dimension of a box that is cubic is 24.8 cm on each edge with an uncertainty of 0.2 cm. What is the volume of the box? What do you estimate to be the uncertainty in the calculated volume?
- 1.50 The distance from Grand Rapids, Michigan, to Detroit is listed in a road atlas as 153 miles. Describe some of the factors that contribute to the uncertainty in this number. To make the number more precise, what would you need to specify and measure?
- 1.51 Perform the following conversions: (a) 5.00 days to s,
 (b) 0.0550 mi to m, (c) \$1.89/gal to dollars per liter,
 (d) 0.510 in./ms to km/hr, (e) 22.50 gal/min to L/s,
 (f) 0.02500 ft³ to cm³.
- **1.52** Carry out the following conversions: (a) 0.105 in. to mm, (b) 0.650 qtto mL, (c) 8.75 μ m/s to km/hr, (d) 1.955 m³ to yd³, (e) \$3.99/lb to dollars per kg, (f) 8.75 lb/ft³ to g/mL.
- 1.53 (a) How many liters of wine can be held in a wine barrel whose capacity is 31 gal? (b) The recommended adult dose of Elixophyllin®, a drug used to treat asthma, is 6 mg/kg of body mass. Calculate the dose in milligrams for a 185-lb person. (c) If an automobile is able to travel 400 km on 47.3 L of gasoline, what is the gas mileage in miles per gallon? (d) When the coffee is brewed according to directions, a pound of coffee beans yields 50 cups of coffee (4 cups = 1 qt). How many kg of coffee are required to produce 200 cups of coffee?

- 1.54 (a) If an electric car is capable of going 225 km on a single charge, how many charges will it need to travel from Seattle, Washington, to San Diego, California, a distance of 1257 mi, assuming that the trip begins with a full charge? (b) If a migrating loon flies at an average speed of 14 m/s, what is its average speed in mi/hr? (c) What is the engine piston displacement in liters of an engine whose displacement is listed as 450 in.³? (d) In March 1989 the *Exxon Valdez* ran aground and spilled 240,000 barrels of crude petroleum off the coast of Alaska. One barrel of petroleum is equal to 42 gal. How many liters of petroleum were spilled?
- 1.55 The density of air at ordinary atmospheric pressure and 25 °C is 1.19 g/L. What is the mass, in kilograms, of the air in a room that measures 14.5 ft \times 16.5 ft \times 8.0 ft?
- **1.56** The concentration of carbon monoxide in an urban apartment is $48 \,\mu g/m^3$. What mass of carbon monoxide in grams is present in a room measuring 10.6 ft \times 14.8 ft \times 20.5 ft?
- 1.57 Gold can be hammered into extremely thin sheets called gold leaf. An architect wants to cover a 100 ft \times 82 ft ceiling with gold leaf that is five–millionths of an inch thick. The density of gold is 19.32 g/cm³, and gold costs \$1654 per troy ounce (1 troy ounce = 31.1034768 g). How much will it cost the architect to buy the necessary gold?
- **1.58** A copper refinery produces a copper ingot weighing 150 lb. If the copper is drawn into wire whose diameter is 7.50 mm, how many feet of copper can be obtained from the ingot? The density of copper is 8.94 g/cm^3 . (Assume that the wire is a cylinder whose volume $V = \pi r^2 h$, where r is its radius and h is its height or length.)

Additional Exercises

- 1.59 (a) Classify each of the following as a pure substance, a solution, or a heterogeneous mixture: a gold coin, a cup of coffee, a wood plank. (b) What ambiguities are there in answering part (a) from the descriptions given?
- 1.60 (a) What is the difference between a hypothesis and a theory?(b) Explain the difference between a theory and a scientific law. Which addresses how matter behaves, and which addresses why it behaves that way?
- **1.61** A sample of ascorbic acid (vitamin C) is synthesized in the laboratory. It contains 1.50 g of carbon and 2.00 g of oxygen. Another sample of ascorbic acid isolated from citrus fruits contains 6.35 g of carbon. How many grams of oxygen does it contain? Which law are you assuming in answering this question?
- 1.62 Ethyl chloride is sold as a liquid (see photo) under pressure for use as a local skin anesthetic. Ethyl chloride boils at 12 °C at atmospheric pressure. When the liquid is sprayed onto the skin, it boils off, cooling and numbing the skin as it vaporizes. (a) What changes of state are involved in this use of ethyl chloride? (b) What is the boiling point of ethyl chloride in degrees Fahrenheit? (c) The bottle shown contains 103.5 mL of ethyl chloride. The density of ethyl chloride at 25 °C is 0.765 g/cm³. What is the mass of ethyl chloride in the bottle?

- 1.63 Two students determine the percentage of lead in a sample as a laboratory exercise. The true percentage is 22.52%. The students' results for three determinations are as follows:
 - (1) 22.52, 22.48, 22.54
 - **(2)** 22.64, 22.58, 22.62

- (a) Calculate the average percentage for each set of data and state which set is the more accurate based on the average. (b) Precision can be judged by examining the average of the deviations from the average value for that data set. (Calculate the average value for each data set; then calculate the average value of the absolute deviations of each measurement from the average.) Which set is more precise?
- 1.64 Is the use of significant figures in each of the following statements appropriate? Why or why not? (a) Apple sold 22,727,000 iPods during the last three months of 2008.
 (b) New York City receives 49.7 inches of rain, on average, per year. (c) In the United States, 0.621% of the population has the surname Brown. (d) You calculate your grade point average to be 3.87562.
- 1.65 What type of quantity (for example, length, volume, density) do the following units indicate? (a) mL, (b) cm², (c) mm³, (d) mg/L, (e) ps, (f) nm, (g) K.
- **1.66** Give the derived SI units for each of the following quantities in base SI units:
 - (a) acceleration = $distance/time^2$
 - (b) force = mass \times acceleration
 - (c) work = force \times distance
 - (d) pressure = force/area
 - (e) power = work/time
 - (f) velocity = distance/time
 - (g) energy = mass \times (velocity)²
- 1.67 The distance from Earth to the Moon is approximately 240,000 mi. (a) What is this distance in meters? (b) The peregrine falcon has been measured as traveling up to 350 km/hr in a dive. If this falcon could fly to the Moon at this speed, how many seconds would it take? (c) The speed of light is 3.00×10^8 m/s. How long does it take for light to travel from Earth to the Moon and back again? (d) Earth travels around the Sun at an average speed of 29.783 km/s. Convert this speed to miles per hour.
- 1.68 Which of the following would you characterize as a pure or nearly pure substance? (a) baking powder; (b) lemon juice; (c) propane gas, used in outdoor gas grills; (d) aluminum foil; (e) ibuprofen; (f) bourbon whiskey; (g) helium gas; (h) clear water pumped from a deep aquifer.
- 1.69 The U.S. quarter has a mass of 5.67 g and is approximately 1.55 mm thick. (a) How many quarters would have to be stacked to reach 575 ft, the height of the Washington Monument? (b) How much would this stack weigh? (c) How much money would this stack contain? (d) The U.S. National Debt Clock showed the outstanding public debt to be \$16,213,166,914,811 on October 28, 2012. How many stacks like the one described would be necessary to pay off this debt?
- 1.70 In the United States, water used for irrigation is measured in acre-feet. An acre-foot of water covers an acre to a depth of exactly 1 ft. An acre is 4840 yd². An acre-foot is enough water to supply two typical households for 1.00 yr. (a) If desalinated water costs \$1950 per acre-foot, how much does desalinated water cost per liter? (b) How much would it cost one household per day if it were the only source of water?
- 1.71 By using estimation techniques, determine which of the following is the heaviest and which is the lightest: a 5-lb bag of potatoes, a 5-kg bag of sugar, or 1 gal of water (density $= 1.0 \, \text{g/mL}$).

- 1.72 Suppose you decide to define your own temperature scale with units of O, using the freezing point (13 °C) and boiling point (360 °C) of oleic acid, the main component of olive oil. If you set the freezing point of oleic acid as 0 °O and the boiling point as 100 °O, what is the freezing point of water on this new scale?
- 1.73 The liquid substances mercury (density = 13.6 g/mL), water (1.00 g/mL), and cyclohexane (0.778 g/mL) do not form a solution when mixed but separate in distinct layers. Sketch how the liquids would position themselves in a test tube.
- **1.74** Two spheres of equal volume are placed on the scales as shown. Which one is more dense?

- 1.75 Water has a density of 0.997 g/cm³ at 25 °C; ice has a density of 0.917 g/cm³ at -10 °C. (a) If a soft-drink bottle whose volume is 1.50 L is completely filled with water and then frozen to -10 °C, what volume does the ice occupy? (b) Can the ice be contained within the bottle?
- 1.76 A 32.65-g sample of a solid is placed in a flask. Toluene, in which the solid is insoluble, is added to the flask so that the total volume of solid and liquid together is 50.00 mL. The solid and toluene together weigh 58.58 g. The density of toluene at the temperature of the experiment is 0.864 g/mL. What is the density of the solid?
- 1.77 A thief plans to steal a gold sphere with a radius of 28.9 cm from a museum. If the gold has a density of 19.3 g/cm³, what is the mass of the sphere in pounds? [The volume of a sphere is $V = (4/3)\pi r^3$.] Is the thief likely to be able to walk off with the gold sphere unassisted?
- 1.78 Automobile batteries contain sulfuric acid, which is commonly referred to as "battery acid." Calculate the number of grams of sulfuric acid in 1.00 gal of battery acid if the solution has a density of 1.28 g/mL and is 38.1% sulfuric acid by mass.
- 1.79 A 40-lb container of peat moss measures $14 \times 20 \times 30$ in. A 40-lb container of topsoil has a volume of 1.9 gal. (a) Calculate the average densities of peat moss and topsoil in units of g/cm^3 . Would it be correct to say that peat moss is "lighter" than topsoil? Explain. (b) How many bags of peat moss are needed to cover an area measuring 15.0 ft \times 20.0 ft to a depth of 3.0 in.?
- **1.80** A package of aluminum foil contains 50 ft² of foil, which weighs approximately 8.0 oz. Aluminum has a density of $2.70 \, \text{g/cm}^3$. What is the approximate thickness of the foil in millimeters?
- 1.81 The total rate at which power used by humans worldwide is approximately 15 TW (terawatts). The solar flux averaged over the sunlit half of Earth is $680 \, \text{W/m}^2$. (assuming no clouds). The area of Earth's disc as seen from the sun is $1.28 \times 10^{14} \, \text{m}^2$. The surface area of Earth is approximately 197,000,000 square miles. How much of Earth's

- surface would we need to cover with solar energy collectors to power the planet for use by all humans? Assume that the solar energy collectors can convert only 10% of the available sunlight into useful power.
- 1.82 In 2005, J. Robin Warren and Barry J. Marshall shared the Nobel Prize in Medicine for discovery of the bacterium *Helicobacter pylori*, and for establishing experimental proof that it plays a major role in gastritis and peptic ulcer disease. The story began when Warren, a pathologist, noticed that bacilli were associated with the tissues taken from patients suffering from ulcers. Look up the history of this case and describe Warren's first hypothesis. What sorts of evidence did it take to create a credible theory based on it?
- 1.83 A 25.0-cm long cylindrical glass tube, sealed at one end, is filled with ethanol. The mass of ethanol needed to fill the tube is found to be 45.23 g. The density of ethanol is 0.789 g/mL. Calculate the inner diameter of the tube in centimeters.
- **1.84** Gold is alloyed (mixed) with other metals to increase its hardness in making jewelry. (a) Consider a piece of gold jewelry that weighs 9.85 g and has a volume of 0.675 cm³. The jewelry contains only gold and silver, which have densities of 19.3 and 10.5 g/cm³, respectively. If the total volume of the jewelry is the sum of the volumes of the gold and silver that it contains, calculate the percentage of gold (by mass) in the jewelry. (b) The relative amount of gold in an alloy is commonly expressed in units of carats. Pure gold is 24 carat, and the percentage of gold in an alloy is given as a percentage of this value. For example, an alloy that is 50% gold is 12 carat. State the purity of the gold jewelry in carats.
- 1.85 Paper chromatography is a simple but reliable method for separating a mixture into its constituent substances. You have a mixture of two vegetable dyes, one red and one blue, that you are trying to separate. You try two different chromatography procedures and achieve the separations shown in the figure. Which procedure worked better? Can you suggest a method to quantify how good or poor the separation was?

- **1.86** Judge the following statements as true or false. If you believe a statement to be false, provide a corrected version.
 - (a) Air and water are both elements.
 - (b) All mixtures contain at least one element and one compound.
 - (c) Compounds can be decomposed into two or more other substances; elements cannot.
 - (d) Elements can exist in any of the three states of matter.
 - (e) When yellow stains in a kitchen sink are treated with bleach water, the disappearance of the stains is due to a physical change.
 - (f) A hypothesis is more weakly supported by experimental evidence than a theory.
 - (g) The number 0.0033 has more significant figures than 0.033.
 - (h) Conversion factors used in converting units always have a numerical value of one.
 - (i) Compounds always contain at least two different elements.
- 1.87 You are assigned the task of separating a desired granular material with a density of 3.62 g/cm³ from an undesired granular material that has a density of 2.04 g/cm³. You want to do this by shaking the mixture in a liquid in which the heavier material will fall to the bottom and the lighter material will float. A solid will float on any liquid that is more dense. Using an Internet-based source or a handbook of chemistry, find the densities of the following substances: carbon tetrachloride, hexane, benzene, and diiodomethane. Which of these liquids will serve your purpose, assuming no chemical interaction between the liquid and the solids?
- 1.88 In 2009, a team from Northwestern University and Western Washington University reported the preparation of a new "spongy" material composed of nickel, molybdenum, and sulfur that excels at removing mercury from water. The density of this new material is 0.20 g/cm³, and its surface area is 1242 m² per gram of material. (a) Calculate the volume of a 10.0-mg sample of this material. (b) Calculate the surface area for a 10.0-mg sample of this material. (c) A 10.0-mL sample of contaminated water had 7.748 mg of mercury in it. After treatment with 10.0 mg of the new spongy material, 0.001 mg of mercury remained in the contaminated water. What percentage of the mercury was removed from the water? (d) What is the final mass of the spongy material after the exposure to mercury?

Atoms, Molecules, and Ions

Look around at the great variety of colors, textures, and other properties in the materials that surround you—the colors in a garden, the texture of the fabric in your clothes, the solubility of sugar in a cup of coffee, or the beauty and complexity of a geode like the one shown to the right. How can we explain the striking and seemingly infinite variety of properties of the materials that make up our world? What makes diamonds transparent and hard? A large crystal of sodium chloride, table salt, looks a bit like a diamond, but is brittle and readily dissolves in water. What accounts for the differences? Why does paper burn, and why does water quench fires? The answers to all such questions lie in the structures of atoms, which determine the physical and chemical properties of matter.

Although the materials in our world vary greatly in their properties, everything is formed from only about 100 elements and, therefore, from only about 100 chemically different kinds of atoms. In a sense, these different atoms are like the 26 letters of the English alphabet that join in different combinations to form the immense number of words in our language. But what rules govern the ways in which atoms combine? How do the properties of a substance relate to the kinds of atoms it contains? Indeed, what is an atom like, and what makes the atoms of one element different from those of another?

In this chapter we introduce the basic structure of atoms and discuss the formation of molecules and ions, thereby providing a foundation for exploring chemistry more deeply in later chapters.

▶ A SECTION THROUGH A GEODE. A geode is a mass of mineral matter (often containing quartz) that accumulates slowly within the shell of a roughly spherical, hollow rock. Eventually, perfectly formed crystals may develop at a geode's center. The colors of a geode depend upon its composition. Here, agate crystallized out as the geode formed.

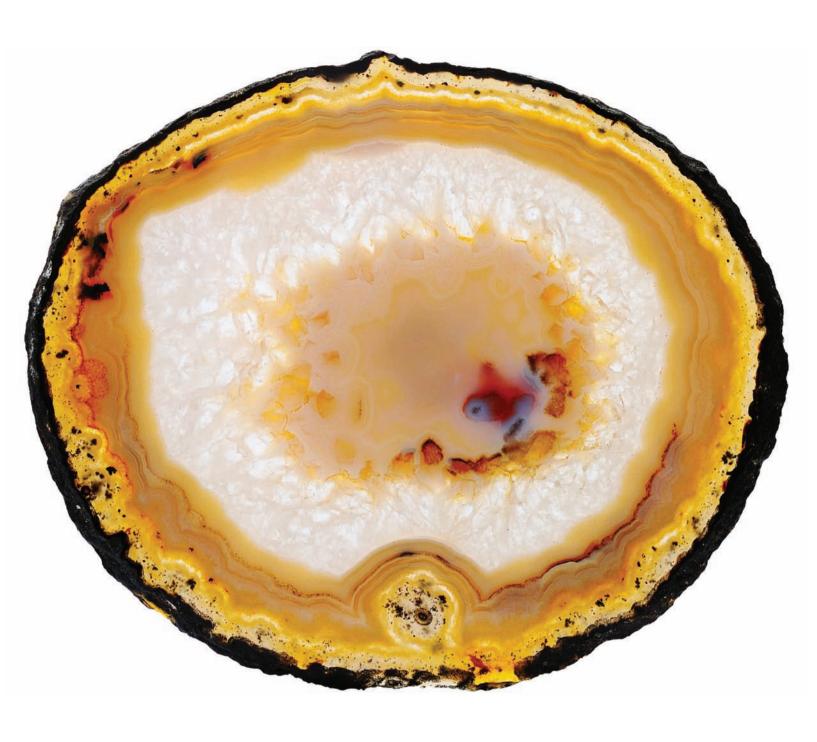

- **2.1 THE ATOMIC THEORY OF MATTER** We begin with a brief history of the notion of *atoms*—the smallest pieces of matter.
- **2.2 THE DISCOVERY OF ATOMIC STRUCTURE** We then look at some key experiments that led to the discovery of *electrons* and to the *nuclear model* of the atom.

2.3 THE MODERN VIEW OF ATOMIC STRUCTURE

We explore the modern theory of atomic structure, including the ideas of *atomic numbers*, *mass numbers*, and *isotopes*.

- 2.4 ATOMIC WEIGHTS We introduce the concept of atomic weights and how they relate to the masses of individual atoms.
- **2.5 THE PERIODIC TABLE** We examine the organization of the *periodic table*, in which elements are put in order of increasing atomic number and grouped by chemical similarity.
- 2.6 MOLECULES AND MOLECULAR COMPOUNDS We discuss the assemblies of atoms called *molecules* and how their compositions are represented by *empirical* and *molecular* formulas.

2.7 IONS AND IONIC COMPOUNDS We learn that atoms can gain or lose electrons to form *ions*. We also look at how to use the periodic table to predict the charges on ions and the empirical formulas of *ionic compounds*.

2.8 NAMING INORGANIC COMPOUNDS We consider the systematic way in which substances are named, called *nomenclature*, and how this nomenclature is applied to inorganic compounds.

2.9 SOME SIMPLE ORGANIC COMPOUNDS We introduce *organic chemistry*, the chemistry of the element carbon.

2.1 | The Atomic Theory of Matter

Philosophers from the earliest times speculated about the nature of the fundamental "stuff" from which the world is made. Democritus (460-370 BCE) and other early Greek philosophers described the material world as made up of tiny indivisible particles that they called atomos, meaning "indivisible" or "uncuttable." Later, however, Plato and Aristotle formulated the notion that there can be no ultimately indivisible particles, and the "atomic" view of matter faded for many centuries during which Aristotelean philosophy dominated Western culture.

The notion of atoms reemerged in Europe during the seventeenth century. As chemists learned to measure the amounts of elements that reacted with one another to form new substances, the ground was laid for an atomic theory that linked the idea of elements with the idea of atoms. That theory came from the work of John Dalton during the period from 1803 to 1807. Dalton's atomic theory was based on four postulates (see ▼ Figure 2.1).

Dalton's theory explains several laws of chemical combination that were known during his time, including the *law of constant composition* (Section 1.2),* based on postulate 4:

In a given compound, the relative numbers and kinds of atoms are constant.

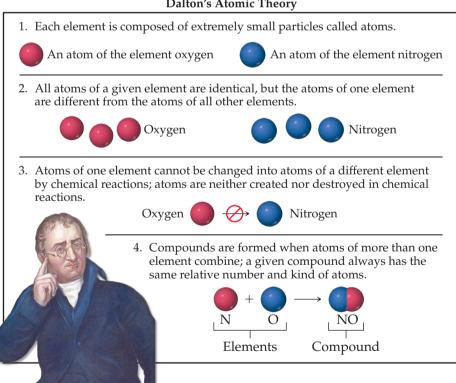

It also explains the **law of conservation of mass**, based on postulate 3:

The total mass of materials present after a chemical reaction is the same as the total mass present before the reaction.

A good theory explains known facts and predicts new ones. Dalton used his theory to deduce the **law of multiple proportions**:

If two elements A and B combine to form more than one compound, the masses of B that can combine with a given mass of A are in the ratio of small whole numbers.

Dalton's Atomic Theory

▲ Figure 2.1 Dalton's atomic theory. John Dalton (1766–1844), the son of a poor English weaver, began teaching at age 12. He spent most of his years in Manchester, where he taught both grammar school and college. His lifelong interest in meteorology led him to study gases, then chemistry, and eventually atomic theory. Despite his humble beginnings, Dalton gained a strong scientific reputation during his lifetime.

^{*}The short chainlike symbol () that precedes the section reference indicates a link to ideas presented earlier in the text.

[†]Dalton, John. "Atomic Theory." 1844.

We can illustrate this law by considering water and hydrogen peroxide, both of which consist of the elements hydrogen and oxygen. In forming water, 8.0 g of oxygen combine with 1.0 g of hydrogen. In forming hydrogen peroxide, 16.0 g of oxygen combine with 1.0 g of hydrogen. Thus, the ratio of the masses of oxygen per gram of hydrogen in the two compounds is 2:1. Using Dalton's atomic theory, we conclude that hydrogen peroxide contains twice as many atoms of oxygen per hydrogen atom than does water.

Give It Some Thought

Compound A contains 1.333 g of oxygen per gram of carbon, whereas compound B contains 2.666 g of oxygen per gram of carbon.

- (a) What chemical law do these data illustrate?
- (b) If compound A has an equal number of oxygen and carbon atoms, what can we conclude about the composition of compound B?

2.2 | The Discovery of Atomic Structure

Dalton based his conclusions about atoms on chemical observations made in the laboratory. By assuming the existence of atoms he was able to account for the laws of constant composition and of multiple proportions. But neither Dalton nor those who followed him during the century after his work was published had any direct evidence for the existence of atoms. Today, however, we can measure the properties of individual atoms and even provide images of them (> Figure 2.2).

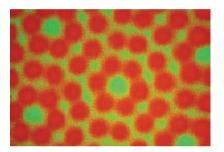

As scientists developed methods for probing the nature of matter, the supposedly indivisible atom began to show signs of a more complex structure, and today we know that the atom is composed of **subatomic particles**. Before we summarize the current model, we briefly consider a few of the landmark discoveries that led to that model. We will see that the atom is composed in part of electrically charged particles, some with a positive charge and some with a negative charge. As we discuss the development of our current model of the atom, keep in mind this fact: *Particles with the same charge repel one another, whereas particles with unlike charges attract one another.*

Cathode Rays and Electrons

During the mid-1800s, scientists began to study electrical discharge through a glass tube pumped almost empty of air (Figure 2.3). When a high voltage was applied to the electrodes in the tube, radiation was produced between the electrodes. This radiation, called **cathode rays**, originated at the negative electrode and traveled to the positive electrode. Although the rays could not be seen, their presence was detected because they cause certain materials to *fluoresce*, or to give off light.

Experiments showed that cathode rays are deflected by electric or magnetic fields in a way consistent with their being a stream of negative electrical charge. The British scientist J. J. Thomson (1856–1940) observed that cathode rays are the same regardless of the identity of the cathode material. In a paper published in 1897, Thomson described cathode rays as streams of negatively charged particles. His paper is generally accepted as the discovery of what became known as the **electron**.

Thomson constructed a cathode-ray tube having a hole in the anode through which a beam of electrons passed. Electrically charged plates and a magnet were positioned perpendicular to the electron beam, and a fluorescent screen was located at one end (Figure 2.4). The electric field deflected the rays in one direction, and the magnetic field deflected them in the opposite direction. Thomson adjusted the strengths of the fields so that the effects balanced each other, allowing the electrons to travel in a straight path to the screen. Knowing the strengths that resulted in the straight path made it possible to calculate a value of 1.76×10^8 coulombs* per gram for the ratio of the electron's electrical charge to its mass.

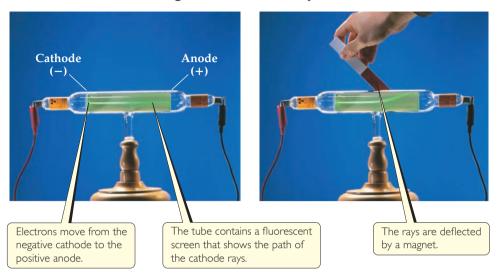

▲ Figure 2.2 An image of the surface of silicon. The image was obtained by a technique called scanning tunneling microscopy. The color was added to the image by computer to help distinguish its features. Each red sphere is a silicon atom.

^{*}The coulomb (C) is the SI unit for electrical charge.

A GO FIGURE

How do we deduce from the figure that the cathode rays travel from cathode to anode?

▲ Figure 2.3 Cathode-ray tube.

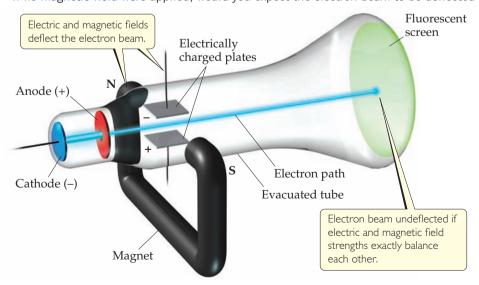

Give It Some Thought

Thomson observed that the cathode rays produced in the cathode-ray tube behaved identically, regardless of the particular metal used as cathode. What is the significance of this observation?

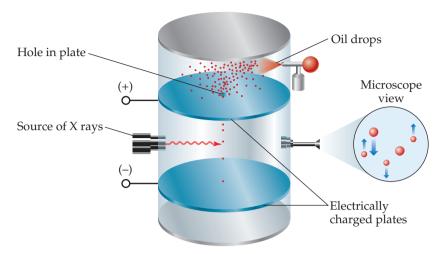

GO FIGURE

If no magnetic field were applied, would you expect the electron beam to be deflected upward or downward by the electric field?

▲ Figure 2.4 Cathode-ray tube with perpendicular magnetic and electric fields. The cathode rays (electrons) originate at the cathode and are accelerated toward the anode, which has a hole in its center. A narrow beam of electrons passes through the hole and travels to the fluorescent screen.

Would the masses of the oil drops be changed significantly by any electrons that accumulate on them?

▲ Figure 2.5 Millikan's oil-drop experiment to measure the charge of the electron. Small drops of oil are allowed to fall between electrically charged plates. The drops pick up extra electrons as a result of irradiation by X-rays and so became negatively charged. Millikan measured how varying the voltage between the plates affected the rate of fall. From these data he calculated the negative charge on the drops. Because the charge on any drop was always some integral multiple of $1.602 \times 10^{-19}\,\text{C}$, Millikan deduced this value to be the charge of a single electron.

Once the charge-to-mass ratio of the electron was known, measuring either quantity allowed scientists to calculate the other. In 1909, Robert Millikan (1868–1953) of the University of Chicago succeeded in measuring the charge of an electron by performing the experiment described in \blacktriangle Figure 2.5. He then calculated the mass of the electron by using his experimental value for the charge, 1.602×10^{-19} C, and Thomson's charge-to-mass ratio, 1.76×10^8 C/g:

Electron mass =
$$\frac{1.602 \times 10^{-19} \, \text{C}}{1.76 \times 10^8 \, \text{C/g}} = 9.10 \times 10^{-28} \, \text{g}$$

This result agrees well with the currently accepted value for the electron mass, 9.10938×10^{-28} g. This mass is about 2000 times smaller than that of hydrogen, the lightest atom.

Radioactivity

In 1896 the French scientist Henri Becquerel (1852–1908) discovered that a compound of uranium spontaneously emits high-energy radiation. This spontaneous emission of radiation is called **radioactivity**. At Becquerel's suggestion, Marie Curie (▶ **Figure 2.6**) and her husband, Pierre, began experiments to identify and isolate the source of radioactivity in the compound. They concluded that it was the uranium atoms.

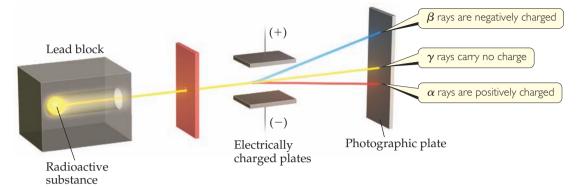

Further study of radioactivity, principally by the British scientist Ernest Rutherford, revealed three types of radiation: alpha (α) , beta (β) , and gamma (γ) . The paths of α and β radiation are bent by an electric field, although in opposite directions; γ radiation is unaffected by the field (Figure 2.7). Rutherford (1871–1937) was a very important figure in this period of atomic science. After working at Cambridge University with J. J. Thomson, he moved to McGill University in Montreal, where he did research on radioactivity that led to his 1908 Nobel Prize in Chemistry. In 1907 he returned to England as a faculty member at Manchester University, where he did his famous α -particle scattering experiments, described below.

Rutherford showed that α and β rays consist of fast-moving particles. In fact, β particles are high-speed electrons and can be considered the radioactive equivalent of cathode rays. They are attracted to a positively charged plate. The α particles have a

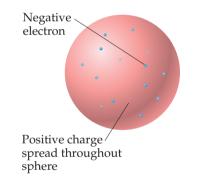

▲ Figure 2.6 Marie Sklodowska Curie (1867–1934). In 1903 Henri Becquerel, Marie Curie, and her husband, Pierre, were jointly awarded the Nobel Prize in Physics for their pioneering work on radioactivity (a term she introduced). In 1911 Marie Curie won a second Nobel Prize, this time in chemistry for her discovery of the elements polonium and radium.

Which of the three kinds of radiation shown consists of electrons? Why are these rays deflected to a greater extent than the others?

▲ Figure 2.7 Behavior of alpha (α) , beta (β) , and gamma (γ) rays in an electric field.

▲ Figure 2.8 J. J. Thomson's plum-pudding model of the atom. Ernest Rutherford and Ernest Marsden proved this model wrong.

positive charge and are attracted to a negative plate. In units of the charge of the electron, β particles have a charge of 1— and α particles a charge of 2+. Each α particle has a mass about 7400 times that of an electron. Gamma radiation is high-energy radiation similar to X rays; it does not consist of particles and carries no charge.

The Nuclear Model of the Atom

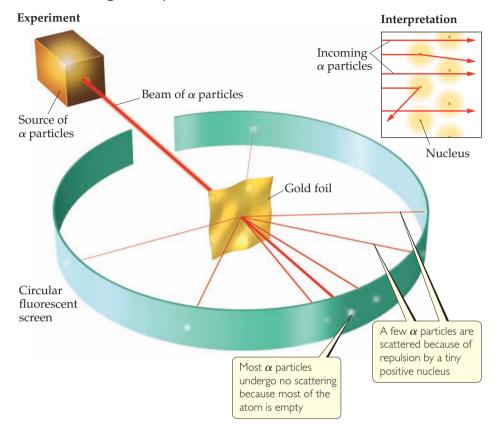

With growing evidence that the atom is composed of smaller particles, scientist gave attention to how the particles fit together. During the early 1900s, Thomson reasoned that because electrons contribute only a very small fraction of an atom's mass they probably are responsible for an equally small fraction of the atom's size. He proposed that the atom consists of a uniform positive sphere of matter in which the mass is evenly distributed and in which the electrons are embedded like raisins in a pudding or seeds in a watermelon (**Figure 2.8**). This *plum-pudding model*, named after a traditional English dessert, was very short-lived.

In 1910, Rutherford was studying the angles at which α particles were deflected, or *scattered*, as they passed through a thin sheet of gold foil (\triangleright Figure 2.9). He discovered that almost all the particles passed directly through the foil without deflection, with a few particles deflected about 1°, consistent with Thomson's plum-pudding model. For the sake of completeness, Rutherford suggested that Ernest Marsden, an undergraduate student working in the laboratory, look for scattering at large angles. To everyone's surprise, a small amount of scattering was observed at large angles, with some particles scattered back in the direction from which they had come. The explanation for these results was not immediately obvious, but they were clearly inconsistent with Thomson's plum-pudding model.

Rutherford explained the results by postulating the **nuclear model** of the atom, in which most of the mass of each gold atom and all of its positive charge reside in a very small, extremely dense region that he called the **nucleus**. He postulated further that most of the volume of an atom is empty space in which electrons move around the nucleus. In the α -scattering experiment, most of the particles passed through the foil unscattered because they did not encounter the minute nucleus of any gold atom. Occasionally, however, an α particle came close to a gold nucleus. In such encounters, the repulsion between the highly positive charge of the gold nucleus and the positive charge of the α particle was strong enough to deflect the particle, as shown in Figure 2.9.

Subsequent experiments led to the discovery of positive particles (**protons**) and neutral particles (**neutrons**) in the nucleus. Protons were discovered in 1919 by Rutherford and neutrons in 1932 by British scientist James Chadwick (1891–1972). Thus, the atom is composed of electrons, protons, and neutrons.

What is the charge on the particles that form the beam?

▲ Figure 2.9 Rutherford's α -Sacttering experiment. When α particles pass through a gold foil, most pass through undeflected but some are scattered, a few at very large angles. According to the plum-pudding model of the atom, the particles should experience only very minor deflections. The nuclear model of the atom explains why a few α particles are deflected at large angles. Although the nuclear atom has been depicted here as a yellow sphere, it is important to realize that most of the space around the nucleus contains only the low–mass electrons.

Give It Some Thought

What happens to most of the α particles that strike the gold foil in Rutherford's experiment? Why do they behave that way?

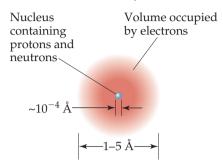

2.3 | The Modern View of Atomic Structure

Since Rutherford's time, as physicists have learned more and more about atomic nuclei, the list of particles that make up nuclei has grown and continues to increase. As chemists, however, we can take a simple view of the atom because only three subatomic particles—the proton, neutron, and electron—have a bearing on chemical behavior.

As noted earlier, the charge of an electron is -1.602×10^{-19} C. The charge of a proton is opposite in sign but equal in magnitude to that of an electron: $+1.602 \times 10^{-19}$ C. The quantity 1.602×10^{-19} C is called the **electronic charge**. For convenience, the charges of atomic and subatomic particles are usually expressed as multiples of this charge rather than in coulombs. Thus, the charge of an electron is 1- and that of a proton is 1+. Neutrons are electrically neutral (which is how they received their name). Every atom has an equal number of electrons and protons, so atoms have no net electrical charge.

What is the approximate diameter of the nucleus in units of pm?

▲ Figure 2.10 The structure of the atom. A cloud of rapidly moving electrons occupies

most of the volume of the atom. The nucleus occupies a tiny region at the center of the atom and is composed of the protons and neutrons. The nucleus contains virtually all the mass of the atom.

Protons and neutrons reside in the tiny nucleus of the atom. The vast majority of an atom's volume is the space in which the electrons reside (◀ Figure 2.10). Most atoms have diameters between 1×10^{-10} m (100 pm) and 5×10^{-10} m (500 pm). A convenient non-SI unit of length used for atomic dimensions is the angstrom (Å), where $1 \text{ Å} = 1 \times 10^{-10} \text{ m}$. Thus, atoms have diameters of approximately 1 - 5 Å. The diameter of a chlorine atom, for example, is 200 pm, or 2.0 Å.

Electrons are attracted to the protons in the nucleus by the electrostatic force that exists between particles of opposite electrical charge. In later chapters we will see that the strength of the attractive forces between electrons and nuclei can be used to explain many of the differences among different elements.

Give It Some Thought

- (a) If an atom has 15 protons, how many electrons does it have?
- **(b)** Where do the protons reside in an atom?

Atoms have extremely small masses. The mass of the heaviest known atom, for example, is approximately 4×10^{-22} g. Because it would be cumbersome to express such small masses in grams, we use the atomic mass unit (amu),* where 1 amu = 1.66054×10^{-24} g. A proton has a mass of 1.0073 amu, a neutron 1.0087 amu, and an electron 5.486 \times 10⁻⁴ amu (∇ Table 2.1). Because it takes 1836 electrons to equal the mass of one proton or one neutron, the nucleus contains most of the mass of an atom.

Table 2.1 Comparison of the Proton, Neutron, and Electron

Particle	Charge	Mass (amu)
Proton	Positive (1+)	1.0073
Neutron	None (neutral)	1.0087
Electron	Negative (1-)	5.486×10^{-4}

SAMPLE **EXERCISE 2.1** Atomic Size

The diameter of a U.S. dime is 17.9 mm, and the diameter of a silver atom is 2.88 Å. How many silver atoms could be arranged side by side across the diameter of a dime?

SOLUTION

The unknown is the number of silver (Ag) atoms. Using the relationship 1 Ag atom = 2.88 Åas a conversion factor relating number of atoms and distance, we start with the diameter of the dime, first converting this distance into angstroms and then using the diameter of the Ag atom to convert distance to number of Ag atoms:

Ag atoms =
$$(17.9 \text{ mm}) \left(\frac{10^{-3} \text{ m}}{1 \text{ mm}} \right) \left(\frac{1 \text{ Å}}{10^{-10} \text{ m}} \right) \left(\frac{1 \text{ Ag atom}}{2.88 \text{ Å}} \right) = 6.22 \times 10^7 \text{ Ag atoms}$$

That is, 62.2 million silver atoms could sit side by side across a dime!

Practice Exercise 1

Which of the following factors determines the size of an atom?

(a) The volume of the nucleus; (b) the volume of space occupied by the electrons of the atom; (c) the volume of a single electron, multiplied by the number of electrons in the atom; (d) The total nuclear charge; (e) The total mass of the electrons surrounding the nucleus.

Practice Exercise 2

The diameter of a carbon atom is 1.54 Å. (a) Express this diameter in picometers. (b) How many carbon atoms could be aligned side by side across the width of a pencil line that is 0.20 mm wide?

^{*}The SI abbreviation for the atomic mass unit is u. We will use the more common abbreviation amu.

The diameter of an atomic nucleus is approximately 10^{-4} Å, only a small fraction of the diameter of the atom as a whole. You can appreciate the relative sizes of the atom and its nucleus by imagining that if the hydrogen atom were as large as a football stadium, the nucleus would be the size of a small marble. Because the tiny nucleus carries most of the mass of the atom in such a small volume, it has an incredibly high density—on the order of 10^{13} – 10^{14} g/cm³. A matchbox full of material of such density would weigh over 2.5 billion tons!

A Closer Look

Basic Forces

Four basic forces are known in nature: (1) gravitational, (2) electromagnetic, (3) strong nuclear, and (4) weak nuclear. *Gravitational forces* are attractive forces that act between all objects in proportion to their masses. Gravitational forces between atoms or between subatomic particles are so small that they are of no chemical significance.

Electromagnetic forces are attractive or repulsive forces that act between either electrically charged or magnetic objects. Electric forces are important in understanding the chemical behavior of atoms. The magnitude of the electric force between two charged particles is given by Coulomb's law: $F = kQ_1Q_2/d^2$, where Q_1 and Q_2 are the magnitudes of the charges on the two particles, d is the distance between their centers, and k is a constant determined by the units for Q and d.

A negative value for the force indicates attraction, whereas a positive value indicates repulsion. Electric forces are of primary importance in determining the chemical properties of elements.

All nuclei except those of hydrogen atoms contain two or more protons. Because like charges repel, electrical repulsion would cause the protons to fly apart if the *strong nuclear force* did not keep them together. This force acts between subatomic particles, as in the nucleus. At this distance, the attractive strong nuclear force is stronger than the positive–positive repulsive electric force and holds the nucleus together.

The *weak nuclear force* is weaker than the electric force but stronger than the gravitational force. We are aware of its existence only because it shows itself in certain types of radioactivity.

Related Exercise: 2.112

Figure 2.10 incorporates the features we have just discussed. Electrons play the major role in chemical reactions. The significance of representing the region containing electrons as an indistinct cloud will become clear in later chapters when we consider the energies and spatial arrangements of the electrons. For now we have all the information we need to discuss many topics that form the basis of everyday uses of chemistry.

Atomic Numbers, Mass Numbers, and Isotopes

What makes an atom of one element different from an atom of another element? The atoms of each element have a *characteristic number of protons*. The number of protons in an atom of any particular element is called that element's **atomic number**. Because an atom has no net electrical charge, the number of electrons it contains must equal the number of protons. All atoms of carbon, for example, have six protons and six electrons, whereas all atoms of oxygen have eight protons and eight electrons. Thus, carbon has atomic number 6, and oxygen has atomic number 8. The atomic number of each element is listed with the name and symbol of the element on the front inside cover of the text.

Atoms of a given element can differ in the number of neutrons they contain and, consequently, in mass. For example, while most atoms of carbon have six neutrons, some have more and some have less. The symbol ${}^{12}_{6}$ C (read "carbon twelve," carbon-12) represents the carbon atom containing six protons and six neutrons, whereas carbon atoms that contain six protons and eight neutrons have mass number 14, are represented as ${}^{14}_{6}$ C or 14 C, and are referred to as carbon-14.

The atomic number is indicated by the subscript; the superscript, called the **mass number**, is the number of protons plus neutrons in the atom:

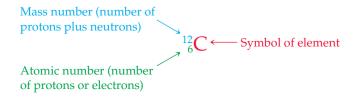

Table 2.2 Some Isotopes of Carbon ⁶	Table 2.2	Some	Isotopes	of	Carbona
--	-----------	------	----------	----	---------

Symbol	Number of Protons	Number of Electrons	Number of Neutrons
¹¹ C	6	6	5
¹² C	6	6	6
¹³ C	6	6	7
¹⁴ C	6	6	8

^aAlmost 99% of the carbon found in nature is ¹²C.

Because all atoms of a given element have the same atomic number, the subscript is redundant and is often omitted. Thus, the symbol for carbon-12 can be represented simply as ¹²C.

Atoms with identical atomic numbers but different mass numbers (that is, same number of protons but different numbers of neutrons) are called isotopes of one another. Several isotopes of carbon are listed in A Table 2.2. We will generally use the notation with superscripts only when referring to a particular isotope of an element. It is important to keep in mind that the isotopes of any given element are all alike chemically. A carbon dioxide molecule that contains a ¹³C atom behaves for all practical purposes identically to one that contains a ¹²C atom.

SAMPLE EXERCISE 2.2

Determining the Number of Subatomic Particles in Atoms

How many protons, neutrons, and electrons are in an atom of (a) ¹⁹⁷Au, (b) strontium-90?

SOLUTION

(a) The superscript 197 is the mass number (protons + neutrons). According to the list of elements given on the front inside cover, gold has atomic number 79. Consequently, an atom of ¹⁹⁷Au has 79 protons, 79 electrons, and 197 - 79 = 118 neutrons. (b) The atomic number of strontium is 38. Thus, all atoms of this element have 38 protons and 38 electrons. The strontium-90 isotope has 90 - 38 =52 neutrons.

Practice Exercise 1

Which of these atoms has the largest number of neutrons in the nucleus? (a) 148 Eu, (b) 157 Dy, (c) 149 Nd, (d) 162 Ho, (e) 159 Gd.

Practice Exercise 2

How many protons, neutrons, and electrons are in an atom of (**a**) ¹³⁸Ba, (**b**) phosphorus-31?

SAMPLE

EXERCISE 2.3 Writing Symbols for Atoms

Magnesium has three isotopes with mass numbers 24, 25, and 26. (a) Write the complete chemical symbol (superscript and subscript) for each. (b) How many neutrons are in an atom of each isotope?

SOLUTION

(a) Magnesium has atomic number 12, so all atoms of magnesium contain 12 protons and 12 electrons. The three isotopes are therefore represented by ${}^{24}_{12}$ Mg, ${}^{25}_{12}$ Mg, and ${}^{26}_{12}$ Mg. (b) The number of neutrons in each isotope is the mass number minus the number of protons. The numbers of neutrons in an atom of each isotope are therefore 12, 13, and 14, respectively.

Practice Exercise 1

Which of the following is an incorrect representation for a neutral atom: (a) ${}_{3}^{6}$ Li, (b) ${}_{6}^{13}$ C, (c) ${}_{30}^{63}$ Cu,(d) ${}_{15}^{30}$ P,(e) ${}_{47}^{108}$ Ag ?

Practice Exercise 2

Give the complete chemical symbol for the atom that contains 82 protons, 82 electrons, and 126 neutrons.

2.4 | Atomic Weights

Atoms are small pieces of matter, so they have mass. In this section we discuss the mass scale used for atoms and introduce the concept of atomic weights.

The Atomic Mass Scale

Scientists of the nineteenth century were aware that atoms of different elements have different masses. They found, for example, that each 100.0 g of water contains 11.1 g of hydrogen and 88.9 g of oxygen. Thus, water contains 88.9/11.1 = 8 times as much oxygen, by mass, as hydrogen. Once scientists understood that water contains two hydrogen atoms for each oxygen atom, they concluded that an oxygen atom must have $2 \times 8 = 16$ times as much mass as a hydrogen atom. Hydrogen, the lightest atom, was arbitrarily assigned a relative mass of 1 (no units). Atomic masses of other elements were at first determined relative to this value. Thus, oxygen was assigned an atomic mass of 16.

Today we can determine the masses of individual atoms with a high degree of accuracy. For example, we know that the 1H atom has a mass of 1.6735 \times 10 $^{-24}$ g and the ^{16}O atom has a mass of 2.6560 \times 10 $^{-23}$ g. As we noted in Section 2.3, it is convenient to use the **atomic mass unit** when dealing with these extremely small masses:

$$1 \text{ amu} = 1.66054 \times 10^{-24} \text{ g} \text{ and } 1 \text{ g} = 6.02214 \times 10^{23} \text{ amu}$$

The atomic mass unit is presently defined by assigning a mass of exactly 12 amu to a chemically unbound atom of the 12 C isotope of carbon. In these units, an 1 H atom has a mass of 1.0078 amu and an 16 O atom has a mass of 15.9949 amu.

Atomic Weight

Most elements occur in nature as mixtures of isotopes. We can determine the *average atomic mass* of an element, usually called the element's **atomic weight**, by summing (indicated by the Greek sigma, Σ) over the masses of its isotopes multiplied by their relative abundances:

Atomic weight =
$$\sum$$
 [(isotope mass) × (fractional isotope abundance)] over all isotopes of the element [2.1]

Naturally occurring carbon, for example, is composed of 98.93% 12 C and 1.07% 13 C. The masses of these isotopes are 12 amu (exactly) and 13.00335 amu, respectively, making the atomic weight of carbon

$$(0.9893)(12 \text{ amu}) + (0.0107)(13.00335 \text{ amu}) = 12.01 \text{ amu}$$

The atomic weights of the elements are listed in both the periodic table and the table of elements front inside cover of this text.

Give It Some Thought

A particular atom of chromium has a mass of 52.94 amu, whereas the atomic weight of chromium is given as 51.99 amu. Explain the difference in the two masses.

SAMPLE EXERCISE 2.4

Calculating the Atomic Weight of an Element from Isotopic Abundances

Naturally occurring chlorine is 75.78% ³⁵Cl (atomic mass 34.969 amu) and 24.22% ³⁷Cl (atomic mass 36.966 amu). Calculate the atomic weight of chlorine.

SOLUTION

We can calculate the atomic weight by multiplying the abundance of each isotope by its atomic mass and summing these products. Because 75.78% = 0.7578 and 24.22% = 0.2422, we have

Atomic weight =
$$(0.7578)(34.969 \text{ amu}) + (0.2422)(36.966 \text{ amu})$$

= $26.50 \text{ amu} + 8.953 \text{ amu}$
= 35.45 amu

This answer makes sense: The atomic weight, which is actually the average atomic mass, is between the masses of the two isotopes and is closer to the value of ³⁵Cl, the more abundant isotope.

Practice Exercise 1

The atomic weight of copper, Cu, is listed as 63.546. Which of the following statements are untrue?

- (a) Not all the atoms of copper have the same number of electrons.
- (b) All the copper atoms have 29 protons in the nucleus.
- (c) The dominant isotopes of Cu must be ⁶³Cu and ⁶⁴Cu.
- (d) Copper is a mixture of at least two isotopes.
- (e) The number of electrons in the copper atoms is independent of atomic mass.

Practice Exercise 2

Three isotopes of silicon occur in nature: 28 Si (92.23%), atomic mass 27.97693 amu; 29 Si (4.68%), atomic mass 28.97649 amu; and 30 Si (3.09%), atomic mass 29.97377 amu. Calculate the atomic weight of silicon.

A Closer Look

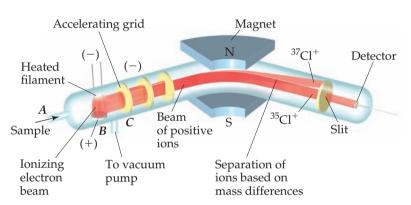

The Mass Spectrometer

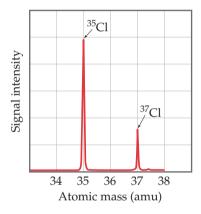

The most accurate means for determining atomic weights is provided by the **mass spectrometer** (∇ Figure 2.11). A gaseous sample is introduced at A and bombarded by a stream of high-energy electrons at B. Collisions between the electrons and the atoms or molecules of the gas produce positively charged particles, called *ions*, that are then accelerated toward a negatively charged grid (C). After the ions pass through the grid, they encounter two slits that allow only a narrow beam of ions to pass. This beam then passes between the poles of a magnet, which deflects the ions into a curved path. For ions with the same charge, the extent of deflection depends on mass—the more massive the ion, the less the deflection. The ions are thereby separated according to their masses. By changing the strength of the magnetic field or the accelerating voltage on the grid, ions of various masses can be selected to enter the detector.

A graph of the intensity of the detector signal versus ion atomic mass is called a *mass spectrum* (▼ Figure 2.12). Analysis of a mass spectrum gives both the masses of the ions reaching the detector and their relative abundances, which are obtained from the signal intensities. Knowing the atomic mass and the abundance of each isotope allows us to calculate the atomic weight of an element, as shown in Sample Exercise 2.4.

Mass spectrometers are used extensively today to identify chemical compounds and analyze mixtures of substances. Any molecule that loses electrons can fall apart, forming an array of positively charged fragments. The mass spectrometer measures the masses of these fragments, producing a chemical "fingerprint" of the molecule and providing clues about how the atoms were connected in the original molecule. Thus, a chemist might use this technique to determine the molecular structure of a newly synthesized compound or to identify a pollutant in the environment.

2.5 | The Periodic Table

As the list of known elements expanded during the early 1800s, attempts were made to find patterns in chemical behavior. These efforts culminated in the development of the periodic table in 1869. We will have much to say about the periodic table in later chapters, but it is so important and useful that you should become acquainted with it now. You will quickly learn that the periodic table is the most significant tool that chemists use for organizing and remembering chemical facts.

Many elements show strong similarities to one another. The elements lithium (Li), sodium (Na), and potassium (K) are all soft, very reactive metals, for example. The elements helium (He), neon (Ne), and argon (Ar) are all very nonreactive gases. If the elements are arranged in order of increasing atomic number, their chemical and physical properties show a repeating, or *periodic*, pattern. For example, each of the soft, reactive metals—lithium, sodium, and potassium—comes immediately after one of the nonreactive gases—helium, neon, and argon, respectively—as shown in **>** Figure 2.13.

If F is a reactive nonmetal, which other element or elements shown here do you expect to also be a reactive nonmetal?

▲ Figure 2.13 Arranging elements by atomic number reveals a periodic pattern of properties. This pattern is the basis of the periodic table.

The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns, is known as the periodic table (**Figure 2.14**). The table shows the atomic number and atomic symbol for each element, and the atomic weight is often given as well, as in this typical entry for potassium:

You may notice slight variations in periodic tables from one book to another or between those in the lecture hall and in the text. These are simply matters of style, or they might concern the particular information included. There are no fundamental differences.

The horizontal rows of the periodic table are called **periods**. The first period consists of only two elements, hydrogen (H) and helium (He). The second and

▲ Figure 2.14 Periodic table of elements.

third periods consist of eight elements each. The fourth and fifth periods contain 18 elements. The sixth period has 32 elements, but for it to fit on a page, 14 of these elements (atomic numbers 57–70) appear at the bottom of the table. The seventh period is incomplete, but it also has 14 of its members placed in a row at the bottom of the table.

The vertical columns are **groups**. The way in which the groups are labeled is somewhat arbitrary. Three labeling schemes are in common use, two of which are shown in Figure 2.14. The top set of labels, which have A and B designations, is widely used in North America. Roman numerals, rather than Arabic ones, are often employed in this scheme. Group 7A, for example, is often labeled VIIA. Europeans use a similar convention that numbers the columns from 1A through 8A and then from 1B through 8B, thereby giving the label 7B (or VIIB) instead of 7A to the group headed by fluorine (F). In an effort to eliminate this confusion, the International Union of Pure and Applied Chemistry (IUPAC) has proposed a convention that numbers the groups from 1 through 18 with no A or B designations, as shown in Figure 2.14. We will use the traditional North American convention with Arabic numerals and the letters A and B.

Elements in a group often exhibit similarities in physical and chemical properties. For example, the "coinage metals"—copper (Cu), silver (Ag), and gold (Au)—belong to group 1B. These elements are less reactive than most metals, which is why they have been traditionally used throughout the world to make coins. Many other groups in the periodic table also have names, listed in **Table 2.3**.

We will learn in Chapters 6 and 7 that elements in a group have similar properties because they have the same arrangement of electrons at the periphery of their atoms. However, we need not wait until then to make good use of the periodic table; after all,

A Closer Look

What Are Coins Made Of?

Copper, silver, and gold were traditionally employed to make coins, but modern coins are typically made from other metals. To be useful for coinage, a metal, or combination of metals (called an *alloy*), must be corrosion resistant. It must also be hard enough to withstand rough usage and yet be of a consistency that permits machines to accurately stamp the coins. Some metals that might otherwise make fine coins—for example, manganese (Mn)—are ruled out because they make the coins too hard to stamp. A third criterion is that the value of the metal in the coin should not be as great as the face value of the coin. For example, if pennies were made today

A photo of a silver dollar from the president series.

from pure copper, the metal would be worth more than a penny, thus inviting smelters to melt down the coins for the value of the metal. Pennies today are largely made of zinc with a copper cladding.

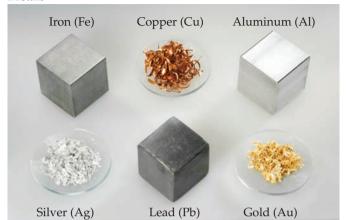

One of the traditional alloys for making coins is a mixture of copper and nickel. Today only the U.S. nickel is made from this alloy, called cupronickel, which consists of 75% copper and 25% nickel. The modern U.S. dollar coin, often referred to as the silver dollar, doesn't contain any silver. It consists of copper (88.5%), zinc (6.0%), manganese (3.5%), and nickel (2.0%). In 2007 the U.S. Congress created a new series of \$1 coins honoring former U.S. presidents. The coins have not been popular, and supplies stockpiled. The U.S. Treasury secretary suspended further production of the coins in December 2011.

Phosphorus (P)

A GO FIGURE

▲ Figure 2.15 Examples of metals and nonmetals.

chemists who knew nothing about electrons developed the table! We can use the table, as they intended, to correlate behaviors of elements and to help us remember many facts.

The color code of Figure 2.14 shows that, except for hydrogen, all the elements on the left and in the middle of the table are **metallic elements**, or **metals**. All the metallic elements share characteristic properties, such as luster and high electrical and heat conductivity, and all of them except mercury (Hg) are solid at room temperature. The metals are separated from the nonmetallic elements, or nonmetals, by a stepped line that runs from boron (B) to a tatine (At). (Note that hydrogen, although on the left side of the table, is a nonmetal.) At room temperature some of the nonmetals are gaseous, some are solid, and one is liquid. Nonmetals generally differ from metals in appearance (A Figure 2.15) and in other physical properties. Many of the elements that lie along the line that separates metals from nonmetals have properties that fall between those of metals and nonmetals. These elements are often referred to as metalloids.

Give It Some Thought

Chlorine is a halogen (Table 2.3). Locate this element in the periodic table.

- (a) What is its symbol?
- (b) In which period and in which group is the element located?
- (c) What is its atomic number?
- (d) Is it a metal or nonmetal?

SAMPLE EXERCISE 2.5

Using the Periodic Table

Which two of these elements would you expect to show the greatest similarity in chemical and physical properties: B, Ca, F, He, Mg, P?

SOLUTION

Elements in the same group of the periodic table are most likely to exhibit similar properties. We therefore expect Ca and Mg to be most alike because they are in the same group (2A, the alkaline earth metals).

Practice Exercise 1

A biochemist who is studying the properties of certain sulfur (S)-containing compounds in the body wonders whether trace amounts of another nonmetallic element might have similar behavior. To which element should she turn her attention? (a) O, (b) As, (c) Se, (d) Cr, (e) P.

Practice Exercise 2

Locate Na (sodium) and Br (bromine) in the periodic table. Give the atomic number of each and classify each as metal, metalloid, or nonmetal.

Hydrogen, H2

Oxygen, O2

Water, H2O

Hydrogen peroxide, H₂O₂

Carbon monoxide, CO

Carbon dioxide, CO₂

Methane, CH₄

Ethylene, C₂H₄

▲ Figure 2.16 Molecular models. Notice how the chemical formulas of these simple molecules correspond to their compositions.

2.6 | Molecules and Molecular Compounds

Even though the atom is the smallest representative sample of an element, only the noble-gas elements are normally found in nature as isolated atoms. Most matter is composed of molecules or ions. We examine molecules here and ions in Section 2.7.

Molecules and Chemical Formulas

Several elements are found in nature in molecular form—two or more of the same type of atom bound together. For example, most of the oxygen in air consists of molecules that contain two oxygen atoms. As we saw in Section 1.2, we represent this molecular oxygen by the **chemical formula** O₂ (read "oh two"). The subscript tells us that two oxygen atoms are present in each molecule. A molecule made up of two atoms is called a diatomic molecule.

Oxygen also exists in another molecular form known as ozone. Molecules of ozone consist of three oxygen atoms, making the chemical formula O₃. Even though "normal" oxygen (O_3) and ozone (O_3) are both composed only of oxygen atoms, they exhibit very different chemical and physical properties. For example, O₂ is essential for life, but O₃ is toxic; O₂ is odorless, whereas O₃ has a sharp, pungent smell.

The elements that normally occur as diatomic molecules are hydrogen, oxygen, nitrogen, and the halogens (H₂, O₂, N₂, F₂, Cl₂, Br₂, and I₂). Except for hydrogen, these diatomic elements are clustered on the right side of the periodic table.

Compounds composed of molecules contain more than one type of atom and are called molecular compounds. A molecule of the compound methane, for example, consists of one carbon atom and four hydrogen atoms and is therefore represented by the chemical formula CH₄. Lack of a subscript on the C indicates one atom of C per methane molecule. Several common molecules of both elements and compounds are shown in **◄** Figure 2.16. Notice how the composition of each substance is given by its chemical formula. Notice also that these substances are composed only of nonmetallic elements. Most molecular substances we will encounter contain only nonmetals.

Molecular and Empirical Formulas

Chemical formulas that indicate the actual numbers of atoms in a molecule are called molecular formulas. (The formulas in Figure 2.16 are molecular formulas.) Chemical formulas that give only the relative number of atoms of each type in a molecule are called **empirical formulas**. The subscripts in an empirical formula are always the smallest possible whole-number ratios. The molecular formula for hydrogen peroxide is H₂O₂, for example, whereas its empirical formula is HO. The molecular formula for ethylene is C_2H_4 , and its empirical formula is CH_2 . For many substances, the molecular formula and the empirical formula are identical, as in the case of water, H₂O.

Give It Some Thought

Consider the following four formulas: SO₂, B₂H₆, CH, C₄H₂O₂. Which of these formulas could be (a) only an empirical formula, (b) only a molecular formula, (c) either a molecular or an empirical formula?

Whenever we know the molecular formula of a compound, we can determine its empirical formula. The converse is not true, however. If we know the empirical formula of a substance, we cannot determine its molecular formula unless we have more information. So why do chemists bother with empirical formulas? As we will see in Chapter 3, certain common methods of analyzing substances lead to the empirical formula only. Once the empirical formula is known, additional experiments can give the information needed to convert the empirical formula to the molecular one. In addition, there are substances that do not exist as isolated molecules. For these substances, we must rely on empirical formulas.

SAMPLE EXERCISE 2.6 Relating Empirical and Molecular Formulas

Write the empirical formulas for (a) glucose, a substance also known as either blood sugar or dextrose—molecular formula $C_6H_{12}O_6$; (b) nitrous oxide, a substance used as an anesthetic and commonly called laughing gas—molecular formula N_2O .

SOLUTION

- (a) The subscripts of an empirical formula are the smallest wholenumber ratios. The smallest ratios are obtained by dividing each subscript by the largest common factor, in this case 6. The resultant empirical formula for glucose is CH₂O.
- (b) Because the subscripts in N_2O are already the lowest integral numbers, the empirical formula for nitrous oxide is the same as its molecular formula, N_2O .

Practice Exercise 1

Tetracarbon dioxide is an unstable oxide of carbon with the following molecular structure:

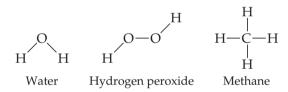

What are the molecular and empirical formulas of this substance? (a) C_2O_2 , CO_2 , (b) C_4O , CO, (c) CO_2 , CO_2 , (d) C_4O_2 , C_2O , (e) C_2O , CO_2 .

Practice Exercise 2

Give the empirical formula for *decaborane*, whose molecular formula is $B_{10}H_{14}$

Picturing Molecules

The molecular formula of a substance summarizes the composition of the substance but does not show how the atoms are joined in the molecule. A **structural formula** shows which atoms are attached to which, as in the following examples:

The atoms are represented by their chemical symbols, and lines are used to represent the bonds that hold the atoms together.

A structural formula usually does not depict the actual geometry of the molecule, that is, the actual angles at which atoms are joined. A structural formula can be written as a *perspective drawing* (Figure 2.17), however, to portray the three-dimensional shape.

Scientists also rely on various models to help visualize molecules. **Ball-and-stick models** show atoms as spheres and bonds as sticks. This type of model has the advantage of accurately representing the angles at which the atoms are attached to one another in a molecule (Figure 2.17). Sometimes the chemical symbols of the elements are superimposed on the balls, but often the atoms are identified simply by color.

A **space-filling model** depicts what a molecule would look like if the atoms were scaled up in size (Figure 2.17). These models show the relative sizes of the atoms, but the angles between atoms, which help define their molecular geometry, are often more difficult to see than in ball-and-stick models. As in ball-and-stick models, the identities of the atoms are indicated by color, but they may also be labeled with the element's symbol.

Give It Some Thought

The structural formula for ethane is

- (a) What is the molecular formula for ethane?
- (b) What is its empirical formula?
- (c) Which kind of molecular model would most clearly show the angles between atoms?

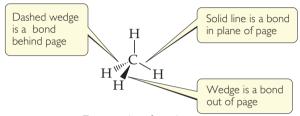

Which model, the ball-and-stick or the space-filling, more effectively shows the angles between bonds around a central atom?

2.7 | Ions and Ionic Compounds

The nucleus of an atom is unchanged by chemical processes, but some atoms can readily gain or lose electrons. If electrons are removed from or added to an atom, a charged particle called an **ion** is formed. An ion with a positive charge is a **cation** (pronounced CAT-ion); a negatively charged ion is an **anion** (AN-ion).

To see how ions form, consider the sodium atom, which has 11 protons and 11 electrons. This atom easily loses one electron. The resulting cation has 11 protons and 10 electrons, which means it has a net charge of 1+.

The net charge on an ion is represented by a superscript. The superscripts +, 2+, and 3+, for instance, mean a net charge resulting from the *loss* of one, two, and three electrons, respectively. The superscripts -, 2-, and 3- represent net charges resulting from the *gain* of one, two, and three electrons, respectively. Chlorine, with 17 protons and 17 electrons, for example, can gain an electron in chemical reactions, producing the $C\Gamma$ ion:

In general, metal atoms tend to lose electrons to form cations and non-metal atoms tend to gain electrons to form anions. Thus, ionic compounds tend to be composed of metals bonded with nonmetals, as in NaCl.

SAMPLE EXERCISE 2.7 Writing Chemical Symbols for Ions

Give the chemical symbol, including superscript indicating mass number, for (a) the ion with 22 protons, 26 neutrons, and 19 electrons; and (b) the ion of sulfur that has 16 neutrons and 18 electrons.

SOLUTION

- (a) The number of protons is the atomic number of the element. A periodic table or list of elements tells us that the element with atomic number 22 is titanium (Ti). The mass number (protons plus neutrons) of this isotope of titanium is 22 + 26 = 48. Because the ion has three more protons than electrons, it has a net charge of 3+ and is designated $^{48}\text{Ti}^{3+}$.
- (b) The periodic table tells us that sulfur (S) has an atomic number of 16. Thus, each atom or ion of sulfur contains 16 protons. We are told that the ion also has 16 neutrons, meaning the mass number is 16 + 16 = 32. Because the ion has 16 protons and 18 electrons, its net charge is 2— and the ion symbol is ³²S²⁻.

In general, we will focus on the net charges of ions and ignore their mass numbers unless the circumstances dictate that we specify a certain isotope.

Practice Exercise 1

In which of the following species is the number of protons less than the number of electrons? (a) Ti^{2+} , (b) P^{3-} , (c) Mn, (d) Se_4^{2-} , (e) Ce^{4+} .

Practice Exercise 2

How many protons, neutrons, and electrons does the ⁷⁹Se²⁻ ion possess?

In addition to simple ions such as Na⁺ and Cl $^-$, there are **polyatomic ions**, such as NH₄⁺ (ammonium ion) and SO₄²⁻ (sulfate ion), which consist of atoms joined as in a molecule, but carrying a net positive or negative charge. Polyatomic ions will be discussed in Section 2.8.

It is important to realize that the chemical properties of ions are very different from the chemical properties of the atoms from which the ions are derived. The addition or removal of one or more electrons produces a charged species with behavior very different from that of its associated atom or group of atoms.

Predicting Ionic Charges

As noted in Table 2.3, the elements of group 8A are called the noble–gas elements. The noble gases are chemically nonreactive elements that form very few compounds. Many atoms gain or lose electrons to end up with the same number of electrons as the noble gas closest to them in the periodic table. We might deduce that atoms tend to acquire the electron arrangements of the noble gases because these electron arrangements are very stable. Nearby elements can obtain these same stable arrangements by losing or gaining electrons. For example, the loss of one electron from an atom of sodium leaves it with the same number of electrons as in a neon atom (10). Similarly, when chlorine gains an electron, it ends up with 18, the same number of electrons as in argon. This simple observation will be helpful for now to account for the formation of ions. A deeper explanation awaits us in Chapter 8, where we discuss chemical bonding.

SAMPLE EXERCISE 2.8 Predicting Ionic Charge

Predict the charge expected for the most stable ion of barium and the most stable ion of oxygen.

SOLUTION

We will assume that barium and oxygen form ions that have the same number of electrons as the nearest noble-gas atom. From the periodic table, we see that barium has atomic number 56. The nearest noble gas is xenon, atomic number 54. Barium can attain a stable arrangement of 54 electrons by losing two electrons, forming the Ba^{2+} cation.

Oxygen has atomic number 8. The nearest noble gas is neon, atomic number 10. Oxygen can attain this stable electron arrangement by gaining two electrons, forming the O^{2-} anion.

Practice Exercise 1

Although it is helpful to know that many ions have the electron arrangement of a noble gas, many elements, especially among the metals, form ions that do not have a noble–gas electron arrangement. Use the periodic table, Figure 2.14, to determine which of the following ions has a noble–gas electron arrangement, and which do not. For those that do, indicate the noble–gas arrangement they match: (a) Ti^{4+} , (b) Mn^{2+} , (c) Pb^{2+} , (d) Te^{2-} , (e) Zn^{2+} .

Practice Exercise 2

Predict the charge expected for the most stable ion of (a) aluminum and (b) fluorine.

The periodic table is very useful for remembering ionic charges, especially those of elements on the left and right sides of the table. As **Figure 2.18** shows, the charges of these ions relate in a simple way to their positions in the table: The group 1A elements (alkali metals) form 1+ ions, the group 2A elements (alkaline earths) form 2+ ions, the group 7A elements (halogens) form 1- ions, and the group 6A elements form 2- ions. (As noted in Practice Exercise 1 of Sample Exercise 2.8, many of the other groups do not lend themselves to such simple rules.)

The most common ions for silver, zinc, and scandium are Ag^+ , Zn^{2+} , and Sc^{3+} . Locate the boxes in which you would place these ions in this table. Which of these ions has the same number of electrons as a noble-gas element?

1A	_														7A	8A
H^+	2A										3A	4A	5A	6A	H-	N
Li+													N ³⁻	O ²⁻	F ⁻	B
Na ⁺	Mg ²⁺	Transition metals								A1 ³⁺			S ²⁻	Cl-	Ĕ	
K ⁺	Ca ²⁺													Se ² –	Br ⁻	Ģ
Rb ⁺	Sr ²⁺													Te ^{2–}	I-	A S E
Cs ⁺	Ba ²⁺															E S

▲ Figure 2.18 Predictable charges of some common ions. Notice that the red stepped line that divides metals from nonmetals also separates cations from anions. Hydrogen forms both 1+ and 1- ions.

Ionic Compounds

A great deal of chemical activity involves the transfer of electrons from one substance to another. ▼ Figure 2.19 shows that when elemental sodium is allowed to react with elemental chlorine, an electron transfers from a sodium atom to a chlorine atom, forming a Na⁺ ion and a Cl[−] ion. Because objects of opposite charges attract, the Na⁺ and the Cl[−] ions bind together to form the compound sodium chloride (NaCl). Sodium chloride, which we know better as common table salt, is an example of an **ionic compound**, a compound made up of cations and anions.

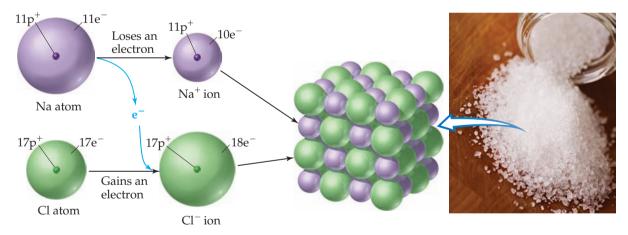

Figure 2.19 Formation of an ionic compound. The transfer of an electron from a Na atom to a Cl atom leads to the formation of a Na⁺ ion and a Cl[−] ion. These ions are arranged in a lattice in solid sodium chloride, NaCl.

We can often tell whether a compound is ionic (consisting of ions) or molecular (consisting of molecules) from its composition. In general, cations are metal ions and anions are nonmetal ions. Consequently, *ionic compounds are generally combinations of metals and nonmetals*, as in NaCl. In contrast, *molecular compounds are generally composed of nonmetals only*, as in H₂O.

SAMPLE EXERCISE 2.9 Identifying Ionic and Molecular Compounds

Which of these compounds would you expect to be ionic: N2O, Na2O, CaCl2, SF4?

SOLUTION

We predict that Na_2O and $CaCl_2$ are ionic compounds because they are composed of a metal combined with a nonmetal. We predict (correctly) that N_2O and SF_4 are molecular compounds because they are composed entirely of nonmetals.

Practice Exercise 1

Which of these compounds are molecular: CBr₄, FeS, P₄O₆, PbF₂?

Practice Exercise 2

Give a reason why each of the following statements is a safe prediction:

- (a) Every compound of Rb with a nonmetal is ionic in character.
- (b) Every compound of nitrogen with a halogen element is a molecular compound.
- (c) The compound MgKr₂ does not exist.
- (d) Na and K are very similar in the compounds they form with nonmetals.
- (e) If contained in an ionic compound, calcium (Ca) will be in the form of the doubly charged ion, Ca^{2+} .

The ions in ionic compounds are arranged in three-dimensional structures, as Figure 2.19 shows for NaCl. Because there is no discrete "molecule" of NaCl, we are able to write only an empirical formula for this substance. This is true for most other ionic compounds.

We can write the empirical formula for an ionic compound if we know the charges of the ions. Because chemical compounds are always electrically neutral, the ions in an ionic compound always occur in such a ratio that the total positive charge equals the total negative charge. Thus, there is one Na⁺ to one Cl⁻ in NaCl, one Ba²⁺ to two Cl⁻ in BaCl₂, and so forth.

As you consider these and other examples, you will see that if the charges on the cation and anion are equal, the subscript on each ion is 1. If the charges are not equal, the charge on one ion (without its sign) will become the subscript on the other ion. For example, the ionic compound formed from Mg (which forms $\mathrm{Mg^{2+}}$ ions) and N (which forms $\mathrm{N^{3-}}$ ions) is $\mathrm{Mg_3N_2}$:

$$Mg^{\textcircled{0}^+}$$
 $N_{\cancel{0}^-}$ \longrightarrow Mg_3N_2

Give It Some Thought

Can you tell from the formula of a substance whether it is ionic or molecular in nature? Why or why not?

Chemistry and Life

Elements Required by Living Organisms

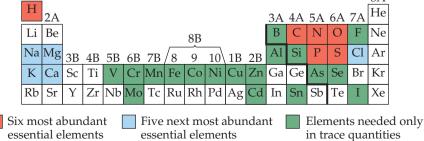

The elements essential to life are highlighted in color in ▼ Figure 2.20. More than 97% of the mass of most organisms is made up of just six of these elements—oxygen, carbon, hydrogen, nitrogen, phosphorus, and sulfur. Water is the most common compound in living organisms, accounting for at least 70% of the mass of most cells. In the solid components of cells, carbon is the most prevalent element by mass. Carbon atoms are found in a vast variety of organic molecules,

bonded either to other carbon atoms or to atoms of other elements. All proteins, for example, contain the carbon-based group

which occurs repeatedly in the molecules. (R is either an H atom or a combination of atoms, such as CH₃.)

In addition, 23 other elements have been found in various living organisms. Five are ions required by all organisms: Ca^{2+} , $C\Gamma$, Mg^{2+} , K^+ , and Na^+ . Calcium ions, for example, are necessary for the formation of bone and transmission of nervous system signals. Many other elements are needed in only very small quantities and consequently are called *trace* elements. For example, trace quantities of copper are required in the diet of humans to aid in the synthesis of hemoglobin.

Related Exercise: 2.102

▲ Figure 2.20 Elements essential to life.

SAMPLE EXERCISE 2 10 II

EXERCISE 2.10 Using Ionic Charge to Write Empirical Formulas for Ionic Compounds

Write the empirical formula of the compound formed by (a) Al^{3+} and Cl^{-} ions, (b) Al^{3+} and O^{2-} ions, (c) Mg^{2+} and NO_{3-} ions.

SOLUTION

- (a) Three Cl⁻ ions are required to balance the charge of one Al³⁺ ion, making the empirical formula AlCl₃.
- (b) Two Al³⁺ ions are required to balance the charge of three O²⁻ ions. A 2:3 ratio is needed to balance the total positive charge of 6+ and the total negative charge of 6-. The empirical formula is Al₂O₃.
- (c) Two NO_3^- ions are needed to balance the charge of one Mg^{2+} , yielding $Mg(NO_3)_2$. Note that the formula for the polyatomic ion, NO_3^- , must be enclosed in parentheses so that it is clear that the subscript 2 applies to all the atoms of that ion.

Practice Exercise 1

For the following ionic compounds formed with S²⁻, what is the empirical formula for the positive ion involved? (a) MnS, (b) Fe₂S₃, (c) MoS₂, (d) K₂S, (e) Ag₂S.

Practice Exercise 2

Write the empirical formula for the compound formed by (a) Na⁺ and PO_4^{3-} , (b) Zn^{2+} and SO_4^{2-} , (c) Fe^{3+} and CO_3^{2-} .

2.8 | Naming Inorganic Compounds

The names and chemical formulas of compounds are essential vocabulary in chemistry. The system used in naming substances is called **chemical nomenclature**, from the Latin words *nomen* (name) and *calare* (to call).

There are more than 50 million known chemical substances. Naming them all would be a hopelessly complicated task if each had a name independent of all others. Many important substances that have been known for a long time, such as water (H_2O) and ammonia (NH_3) , do have traditional names (called *common names*). For most substances, however, we rely on a set of rules that leads to an informative and unique name for each substance, one that conveys the composition of the substance.

The rules for chemical nomenclature are based on the division of substances into categories. The major division is between organic and inorganic compounds. *Organic compounds* contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements. All others are *inorganic compounds*. Early chemists associated organic compounds with plants and animals and inorganic compounds with the nonliving portion of our world. Although this distinction is no longer pertinent, the classification between organic and inorganic compounds continues to be useful. In this section we consider the basic rules for naming three categories of inorganic compounds: ionic compounds, molecular compounds, and acids.

Names and Formulas of Ionic Compounds

Recall from Section 2.7 that ionic compounds usually consist of metal ions combined with nonmetal ions. The metals form the cations, and the nonmetals form the anions.

1. Cations

a. *Cations formed from metal atoms have the same name as the metal:*

Na ⁺ sodium ion	Zn ²⁺ zinc ion	Al^{3+}	aluminum ion
----------------------------	---------------------------	-----------	--------------

b. If a metal can form cations with different charges, the positive charge is indicated by a Roman numeral in parentheses following the name of the metal:

Fe ²⁺	iron(II) ion	Cu ⁺	copper(I) ion
Fe ³⁺	iron(III) ion	Cu ²⁺	copper(II) ion

Ions of the same element that have different charges have different properties, such as different colors (◀ Figure 2.21).

GO FIGURE

Is the difference in properties we see between the two substances in Figure 2.21 a difference in physical or chemical properties?

▲ Figure 2.21 Different ions of the same element have different properties. Both substances shown are compounds of iron. The substance on the left is Fe_3O_4 , which contains Fe^{2+} and Fe^{3+} ions. The substance on the right is Fe_2O_3 , which contains Fe^{3+} ions.

Most metals that form cations with different charges are *transition metals*, elements that occur in the middle of the periodic table, from group 3B to group 2B (as indicated on the periodic table on the front inside cover of this book). The metals that form only one cation (only one possible charge) are those of group 1A and group 2A, as well as Al^{3+} (group 3A) and two transition-metal ions: Ag^+ (group 1B) and Zn^{2+} (group 2B). Charges are not expressed when naming these ions. However, if there is any doubt in your mind whether a metal forms more than one cation, use a Roman numeral to indicate the charge. It is never wrong to do so, even though it may be unnecessary.

An older method still widely used for distinguishing between differently charged ions of a metal uses the endings -ous and -ic added to the root of the element's Latin name:

Fe ²⁺	ferrous ion	Cu ⁺	cuprous ion
Fe ³⁺	ferric ion	Cu ²⁺	cupric ion

Although we will only rarely use these older names in this text, you might encounter them elsewhere.

c. Cations formed from nonmetal atoms have names that end in -ium:

NH ₄ ⁺ ammon <mark>ium</mark> ion	H ₃ O ⁺ hydronium ion
---	---

These two ions are the only ions of this kind that we will encounter frequently in the text.

The names and formulas of some common cations are shown in ▼ Table 2.4 and on the back inside cover of the text. The ions on the left side in Table 2.4 are

Table 2.4	Common (Common Cations ^a									
Charge	Formula	Name	Formula	Name							
1+	H ⁺	hydrogen ion	$\mathrm{NH_4}^+$	ammonium ion							
	Li ⁺	lithium ion	Cu ⁺	copper(I) or cuprous ion							
	Na ⁺	sodium ion									
	K ⁺	potassium ion									
	Cs ⁺	cesium ion									
	Ag^+	silver ion									
2+	Mg ²⁺	magnesium ion	Co ²⁺	cobalt(II) or cobaltous ion							
	Ca ²⁺	calcium ion	Cu ²⁺	copper(II) or cupric ion							
	Sr ²⁺	strontium ion	Fe ²⁺	iron(II) or ferrous ion							
	Ba ²⁺	barium ion	Mn ²⁺	manganese(II) or manganous ion							
	Zn ²⁺	zinc ion	Hg_2^{2+}	mercury(I) or mercurous ion							
	Cd^{2+}	cadmium ion	Hg ²⁺	mercury(II) or mercuric ion							
			Ni ²⁺	nickel(II) or nickelous ion							
			Pb ²⁺	lead(II) or plumbous ion							
			Sn ²⁺	tin(II) or stannous ion							
3+	Al ³⁺	aluminum ion	Cr ³⁺	chromium(III) or chromic ion							
			Fe ³⁺	iron(III) or ferric ion							

^aThe ions we use most often in this course are in boldface. Learn them first.

the monatomic ions that do not have more than one possible charge. Those on the right side are either polyatomic cations or cations with more than one possible charge. The ${\rm Hg_2}^{2^+}$ ion is unusual because, even though it is a metal ion, it is not monatomic. It is called the mercury(I) ion because it can be thought of as two ${\rm Hg}^+$ ions bound together. The cations that you will encounter most frequently in this text are shown in boldface. You should learn these cations first.

Give It Some Thought

- (a) Why is CrO named using a Roman numeral, chromium(II) oxide, whereas CaO named without a Roman numeral, calcium oxide?
- (b) What does the -ium ending on the name ammonium tell you about the composition of the ion?

2. Anions

a. The names of monatomic anions are formed by replacing the ending of the name of the element with -ide:

A few polyatomic anions also have names ending in -ide:

b. Polyatomic anions containing oxygen have names ending in either -ate or -ite and are called **oxyanions**. The -ate is used for the most common or representative oxyanion of an element, and -ite is used for an oxyanion that has the same charge but one O atom fewer:

NO_3^-	nitr <mark>ate</mark> ion	$SO_4^{\ 2-}$	sulfate ion
NO_2^-	nitr <mark>ite</mark> ion	50_3^{2-}	sulfite ion

Prefixes are used when the series of oxyanions of an element extends to four members, as with the halogens. The prefix *per*-indicates one more O atom than the oxyanion ending in *-ate*; *hypo-* indicates one O atom fewer than the oxyanion ending in *-ite*:

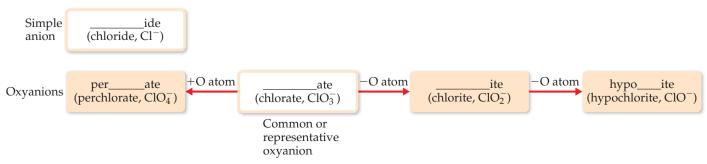

ClO ₄	perchlorate ion (one more O atom than chlorate)
ClO ₃	chlorate ion
ClO ₂	chlorite ion (one O atom fewer than chlorate)
ClO ⁻	hypochlorite ion (one O atom fewer than chlorite)

These rules are summarized in **▼** Figure 2.22.

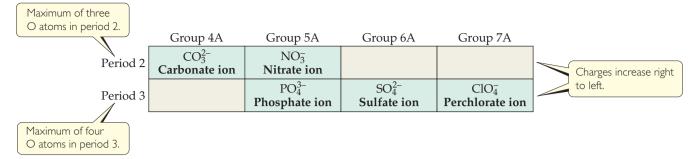

GO FIGURE

Name the anion obtained by removing one oxygen atom from the perbromate ion, BrO₄-.

▲ Figure 2.22 Procedure for naming anions. The first part of the element's name, such as "chlor" for chlorine or "sulf" for sulfur, goes in the blank.

▲ Figure 2.23 Common oxyanions. The composition and charges of common oxyanions are related to their location in the periodic table.

What information is conveyed by the endings -ide, -ate, and -ite in the name of an anion?

▲ Figure 2.23 can help you remember the charge and number of oxygen atoms in the various oxyanions. Notice that C and N, both period 2 elements, have only three O atoms each, whereas the period 3 elements P, S, and Cl have four O atoms each. Beginning at the lower right in Figure 2.23, note that ionic charge increases from right to left, from 1− for ClO_4^- to 3− for PO_4^{3-} . In the second period the charges also increase from right to left, from 1− for NO_3^- to 2− for CO_3^{2-} . Notice also that although each of the anions in Figure 2.23 ends in -ate, the ClO_4^- ion also has a per- prefix.

Give It Some Thought

Predict the formulas for the borate ion and silicate ion, assuming they contain a single B and Si atom, respectively, and follow the trends shown in Figure 2.23.

SAMPLE EXERCISE 2.11 Determining the Formula of an Oxyanion from Its Name

Based on the formula for the sulfate ion, predict the formula for (a) the selenate ion and (b) the selenite ion. (Sulfur and selenium are both in group 6A and form analogous oxyanions.)

SOLUTION

- (a) The sulfate ion is ${\rm SO_4}^{2-}$. The analogous selenate ion is therefore ${\rm SeO_4}^{2-}$.
- (b) The ending *-ite* indicates an oxyanion with the same charge but one O atom fewer than the corresponding oxyanion that ends in *-ate*. Thus, the formula for the selenite ion is SeO₃²⁻.

Practice Exercise 1

Which of the following oxyanions is incorrectly named? (a) ClO_2^- , chlorate; (b) IO_4^- , periodate; (c) SO_3^{2-} , sulfite; (d) IO_3^- , iodate; (e) SeO_4^{2-} , selenate.

Practice Exercise 2

The formula for the bromate ion is analogous to that for the chlorate ion. Write the formula for the hypobromite and bromite ions.

c. Anions derived by adding H^+ to an oxyanion are named by adding as a prefix the word hydrogen or dihydrogen, as appropriate:

CO ₃ ²⁻	carbonate ion	PO ₄ ³⁻	phosphate ion
HCO_3^-	hydrogen carbonate ion	$\mathrm{H_2PO_4}^-$	dihydrogen phosphate ion

Notice that each H^+ added reduces the negative charge of the parent anion by one. An older method for naming some of these ions uses the prefix bi-. Thus, the $\mathrm{HCO_3}^-$ ion is commonly called the bicarbonate ion, and $\mathrm{HSO_4}^-$ is sometimes called the bisulfate ion.

The names and formulas of the common anions are listed in Table 2.5 and on the back inside cover of the text. Those anions whose names end in -ide are listed

Table 2.5	Common Anions ^a			
Charge	Formula	Name	Formula	Name
1-	H_	hydride ion	CH ₃ COO ⁻ (or C ₂ H ₃ O ₂ ⁻)	acetate ion
	F ⁻	fluoride ion	ClO ₃	chlorate ion
	Cl ⁻	chloride ion	ClO ₄ -	perchlorate ion
	Br ⁻	bromide ion	NO ₃	nitrate ion
	I-	iodide ion	$\mathrm{MnO_4}^-$	permanganate ion
	CN ⁻	cyanide ion		
	OH-	hydroxide ion		
2-	O ²⁻	oxide ion	CO ₃ ²⁻	carbonate ion
	$O_2^{\ 2-}$	peroxide ion	CrO ₄ ²⁻	chromate ion
	S ²⁻	sulfide ion	Cr ₂ O ₇ ²⁻	dichromate ion
			SO ₄ ²⁻	sulfate ion
3-	N ³⁻	nitride ion	PO ₄ ³⁻	phosphate ion

^aThe ions we use most often are in boldface. Learn them first.

on the left portion of Table 2.5, and those whose names end in *-ate* are listed on the right. The most common of these ions are shown in boldface. You should learn names and formulas of these anions first. The formulas of the ions whose names end with *-ite* can be derived from those ending in *-ate* by removing an O atom. Notice the location of the monatomic ions in the periodic table. Those of group 7A always have a 1- charge (F^- , CI^- , Br^- , and I^-), and those of group 6A have a 2- charge (O^{2-} and S^{2-}).

3. Ionic Compounds

Names of ionic compounds consist of the cation name followed by the anion name:

CaCl ₂	calcium chloride
$Al(NO_3)_3$	aluminum nitrate
$Cu(ClO_4)_2$	copper(II) perchlorate (or cupric perchlorate)

In the chemical formulas for aluminum nitrate and copper(II) perchlorate, parentheses followed by the appropriate subscript are used because the compounds contain two or more polyatomic ions.

SAMPLE EXERCISE 2.12 Determining the Names of Ionic Compounds from Their Formulas

Name the ionic compounds (a) K_2SO_4 , (b) $Ba(OH)_2$, (c) $FeCl_3$.

SOLUTION

In naming ionic compounds, it is important to recognize polyatomic ions and to determine the charge of cations with variable charge.

- (a) The cation is K^+ , the potassium ion, and the anion is $SO_4^{\ 2^-}$, the sulfate ion, making the name potassium sulfate. (If you thought the compound contained S^{2^-} and O^{2^-} ions, you failed to recognize the polyatomic sulfate ion.)
- (b) The cation is Ba²⁺, the barium ion, and the anion is OH⁻, the hydroxide ion: barium hydroxide.
- (c) You must determine the charge of Fe in this compound because an iron atom can form more than one cation. Because the compound contains three chloride ions, Cl⁻, the cation must be Fe³⁺, the

iron(III), or ferric, ion. Thus, the compound is iron(III) chloride or ferric chloride.

Practice Exercise 1

Which of the following ionic compounds is incorrectly named? (a) $Zn(NO_3)_2$, zinc nitrate; (b) $TeCl_4$, tellurium(IV) chloride; (c) Fe_2O_3 , diiron oxide; (d) BaO, barium oxide; (e) $Mn_3(PO_4)_2$, manganese (II) phosphate.

Practice Exercise 2

Name the ionic compounds (a) NH_4Br , (b) Cr_2O_3 , (c) $Co(NO_3)_2$.

Calcium bicarbonate is also called calcium hydrogen carbonate. (a) Write the formula for this compound, (b) predict the formulas for potassium bisulfate and lithium dihydrogen phosphate.

Names and Formulas of Acids

Acids are an important class of hydrogen-containing compounds, and they are named in a special way. For our present purposes, an *acid* is a substance whose molecules yield hydrogen ions (H^+) when dissolved in water. When we encounter the chemical formula for an acid at this stage of the course, it will be written with H as the first element, as in HCl and H_2SO_4 .

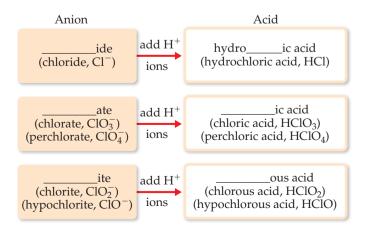

An acid is composed of an anion connected to enough H^+ ions to neutralize, or balance, the anion's charge. Thus, the SO_4^{2-} ion requires two H^+ ions, forming H_2SO_4 . The name of an acid is related to the name of its anion, as summarized in Figure 2.24.

1. Acids containing anions whose names end in -ide are named by changing the -ide ending to -ic, adding the prefix hydro- to this anion name, and then following with the word acid:

Anion	Corresponding Acid	
Cl ⁻ (chloride)	HCl (hydrochloric acid)	
S ²⁻ (sulfide)	H ₂ S (hydrosulfuric acid)	

2. Acids containing anions whose names end in -ate or -ite are named by changing -ate to -ic and -ite to -ous and then adding the word acid. Prefixes in the anion name are retained in the name of the acid:

Anion		Corresponding Acid	
ClO ₄	(perchlorate)	HClO ₄	(perchloric acid)
ClO_3^-	(chlorate)	$HClO_3$	(chloric acid)
ClO ₂	(chlorite)	HClO ₂	(chlorous acid)
ClO ⁻	(hypochlorite)	HClO	(hypochlorous acid)

▲ Figure 2.24 How anion names and acid names relate. The prefixes *per-* and *hypo-* are retained in going from the anion to the acid.

Name the acid obtained by adding H⁺ to the iodate ion, IO₃⁻.

SAMPLE EXERCISE 2.13 Relating the Names and Formulas of Acids

Name the acids (a) HCN, (b) HNO₃, (c) H_2SO_4 , (d) H_2SO_3 .

SOLUTION

- (a) The anion from which this acid is derived is CN⁻, the cyanide ion. Because this ion has an -ide ending, the acid is given a hydro- prefix and an -ic ending: hydrocyanic acid. Only water solutions of HCN are referred to as hydrocyanic acid. The pure compound, which is a gas under normal conditions, is called hydrogen cyanide. Both hydrocyanic acid and hydrogen cyanide are extremely toxic.
- (b) Because NO₃⁻ is the nitrate ion, HNO₃ is called nitric acid (the -ate ending of the anion is replaced with an -ic ending in naming the acid).
- (c) Because SO_4^{2-} is the sulfate ion, H_2SO_4 is called sulfuric acid.

(d) Because SO_3^{2-} is the sulfite ion, H_2SO_3 is sulfurous acid (the *-ite* ending of the anion is replaced with an *-ous* ending).

Practice Exercise 1

Which of the following acids are incorrectly named? For those that are, provide a correct name or formula. (a) hydrocyanic acid, HCN; (b) nitrous acid, HNO₃; (c) perbromic acid, HBrO₄; (d) iodic acid, HI; (e) selenic acid, HSeO₄.

Practice Exercise 2

Give the chemical formulas for (a) hydrobromic acid, (b) carbonic acid.

Names and Formulas of Binary Molecular Compounds

The procedures used for naming *binary* (two-element) molecular compounds are similar to those used for naming ionic compounds:

- 1. The name of the element farther to the left in the periodic table (closest to the metals) is usually written first. An exception occurs when the compound contains oxygen and chlorine, bromine, or iodine (any halogen except fluorine), in which case oxygen is written last.
- **2.** If both elements are in the same group, the one closer to the bottom of the table is named first.
- 3. The name of the second element is given an -ide ending.
- **4.** *Greek prefixes* (**◀ Table 2.6**) indicate the number of atoms of each element. (Exception: The prefix *mono* is never used with the first element.) When the prefix ends in *a* or *o* and the name of the second element begins with a vowel, the *a* or *o* of the prefix is often dropped.

The following examples illustrate these rules:

Cl ₂ O	dichlorine monoxide	NF ₃	nitrogen <mark>tri</mark> fluoride
N_2O_4	dinitrogen tetroxide	$P_{4}S_{10}$	tetraphosphorus decasulfide

Rule 4 is necessary because we cannot predict formulas for most molecular substances the way we can for ionic compounds. Molecular compounds that contain hydrogen and one other element are an important exception, however. These compounds can be treated as if they were neutral substances containing H^+ ions and anions. Thus, you can predict that the substance named hydrogen chloride has the formula HCl, containing one H^+ to balance the charge of one $C\Gamma^-$. (The name *hydrogen chloride* is used only for the pure compound; water solutions of HCl are called hydrochloric acid. The distinction, which is important, will be explained in Section 4.1.) Similarly, the formula for hydrogen sulfide is H_2S because two H^+ ions are needed to balance the charge on S^{2-} .

Table 2.6 Prefixes Used in Naming Binary Compounds Formed between Nonmetals

Prefix	Meaning
Mono-	1
Di-	2
Tri-	3
Tetra-	4
Penta-	5
Неха-	6
Hepta-	7
Octa-	8
Nona-	9
Deca-	10

Is SOCI₂ a binary compound?

SAMPLE

EXERCISE 2.14 Relating the Names and Formulas of Binary Molecular Compounds

Name the compounds (a) SO₂, (b) PCl₅, (c) Cl₂O₃.

SOLUTION

The compounds consist entirely of nonmetals, so they are molecular rather than ionic. Using the prefixes in Table 2.6, we have (a) sulfur dioxide, (b) phosphorus pentachloride, (c) dichlorine trioxide.

Practice Exercise 1

Give the name for each of the following binary compounds of carbon: (a) CS₂, (b) CO, (c) C_3O_2 , (d) CBr_4 , (e) CF.

Practice Exercise 2

Give the chemical formulas for (a) silicon tetrabromide, (b) disulfur dichloride, (c) diphosphorus hexaoxide.

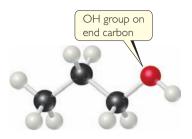

2.9 | Some Simple Organic Compounds

The study of compounds of carbon is called **organic chemistry**, and as noted earlier, compounds that contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements, are called organic compounds. Organic compounds are a very important part of chemistry, far outnumbering all other types of chemical substances. We will examine organic compounds in a systematic way in Chapter 24, but you will encounter many examples of them throughout the text. Here we present a brief introduction to some of the simplest organic compounds and the ways in which they are named.

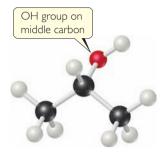

Alkanes

Compounds that contain only carbon and hydrogen are called hydrocarbons. In the simplest class of hydrocarbons, alkanes, each carbon is bonded to four other atoms. The three smallest alkanes are methane (CH_4) , ethane (C_3H_6) , and propane (C_3H_8) . The structural formulas of these three alkanes are as follows:

Although hydrocarbons are binary molecular compounds, they are not named like the binary inorganic compounds discussed in Section 2.8. Instead, each alkane has a name that ends in -ane. The alkane with four carbons is called butane. For alkanes with five or more carbons, the names are derived from prefixes like those in Table 2.6. An alkane with eight carbon atoms, for example, is octane (C_8H_{18}) , where the octa- prefix for eight is combined with the *-ane* ending for an alkane.

1-Propanol

2-Propanol

▲ Figure 2.25 The two forms (isomers) of propanol.

Some Derivatives of Alkanes

Other classes of organic compounds are obtained when one or more hydrogen atoms in an alkane are replaced with *functional groups*, which are specific groups of atoms. An **alcohol**, for example, is obtained by replacing an H atom of an alkane with an —OH group. The name of the alcohol is derived from that of the alkane by adding an *-ol* ending:

Alcohols have properties that are very different from those of the alkanes from which the alcohols are obtained. For example, methane, ethane, and propane are all colorless gases under normal conditions, whereas methanol, ethanol, and propanol are colorless liquids. We will discuss the reasons for these differences in Chapter 11.

The prefix "1" in the name 1-propanol indicates that the replacement of H with OH has occurred at one of the "outer" carbon atoms rather than the "middle" carbon atom. A different compound, called either 2-propanol or isopropyl alcohol, is obtained when the OH functional group is attached to the middle carbon atom (Figure 2.25).

Compounds with the same molecular formula but different arrangements of atoms are called **isomers**. There are many different kinds of isomers, as we will discover later in this book. What we have here with 1-propanol and 2-propanol are *structural isomers*, compounds having the same molecular formula but different structural formulas.

As already noted, many different functional groups can replace one or more of the hydrogens on an alkane; for example, one or more of the halogens, or a special grouping of carbon and oxygen atoms, such as the carboxylic acid group, —COOH. Here are a few examples of functional groups you will be encountering in the chapters that lie ahead (the functional group is outlined in blue):

Give It Some Thought

Draw the structural formulas of the two isomers of butane, C₄H₁₀.

Much of the richness of organic chemistry is possible because organic compounds can form long chains of carbon–carbon bonds. The series of alkanes that begins with methane, ethane, and propane and the series of alcohols that begins with methanol, ethanol, and propanol can both be extended for as long as we desire, in principle. The properties of alkanes and alcohols change as the chains get longer. Octanes, which are

alkanes with eight carbon atoms, are liquids under normal conditions. If the alkane series is extended to tens of thousands of carbon atoms, we obtain *polyethylene*, a solid substance that is used to make thousands of plastic products, such as plastic bags, food containers, and laboratory equipment.

SAMPLE EXERCISE 2.15

EXERCISE 2.15 Writing Structural and Molecular Formulas for Hydrocarbons

Assuming the carbon atoms in *pentane* are in a linear chain, write (a) the structural formula and (b) the molecular formula for this alkane.

SOLUTION

(a) Alkanes contain only carbon and hydrogen, and each carbon is attached to four other atoms. The name pentane contains the prefix penta- for five (Table 2.6), and we are told that the carbons are in a linear chain. If we then add enough hydrogen atoms to make four bonds to each carbon, we obtain the structural formula

This form of pentane is often called *n*-pentane, where the *n*- stands for "normal" because all five carbon atoms are in one line in the structural formula.

(b) Once the structural formula is written, we determine the molecular formula by counting the atoms present. Thus, n-pentane has the molecular formula C_5H_{12} .

Practice Exercise 1

(a) What is the molecular formula of hexane, the alkane with six carbons? (b) What are the name and molecular formula of an alcohol derived from hexane?

Practice Exercise 2

These two compounds have "butane" in their name. Are they isomers?

Strategies in Chemistry

How to Take a Test

At about this time in your study of chemistry, you are likely to face your first hour-long examination. The best way to prepare is to study, do homework diligently, and get help from the instructor on any material that is unclear or confusing. (See the advice for learning and studying chemistry presented in the preface of the book.) We present here some general guidelines for taking tests.

Depending on the nature of your course, the exam could consist of a variety of different types of questions.

1. Multiple-choice questions In large-enrollment courses, the most common kind of test question is the multiple-choice question. Many of the practice exercise problems in this book are written in this format to give you practice at this style of question. When faced with this type of problem the first thing to realize is that the instructor has written the question so that at first glance all the answers appear to be correct. Thus, you should not jump to the conclusion that because one of the choices looks correct, it must be correct.

If a multiple-choice question involves a calculation, do the calculation, check your work, and *only then* compare your answer with the choices. Keep in mind, though, that your instructor has anticipated the most common errors you might make in solving a given problem and has probably listed the incorrect answers resulting from those errors. Always double-check your reasoning and use dimensional analysis to arrive at the correct numeric answer and the correct units.

In multiple-choice questions that do not involve calculations, if you are not sure of the correct choice, eliminate all the choices

- you know for sure to be incorrect. The reasoning you use in eliminating incorrect choices may offer insight into which of the remaining choices is correct.
- 2. Calculations in which you must show your work In questions of this kind, you may receive partial credit even if you do not arrive at the correct answer, depending on whether the instructor can follow your line of reasoning. It is important, therefore, to be neat and organized in your calculations. Pay particular attention to what information is given and to what your unknown is. Think about how you can get from the given information to your unknown.

You may want to write a few words or a diagram on the test paper to indicate your approach. Then write out your calculations as neatly as you can. Show the units for every number you write down, and use dimensional analysis as much as you can, showing how units cancel.

3. Questions requiring drawings Questions of this kind will come later in the course, but it is useful to talk about them here. (You should review this box before each exam to remind yourself of good exam-taking practices.) Be sure to label your drawing as completely as possible.

Finally, if you find that you simply do not understand how to arrive at a reasoned response to a question, do not linger over the question. Put a check next to it and go on to the next one. If time permits, you can come back to the unanswered questions, but lingering over a question when nothing is coming to mind is wasting time you may need to finish the exam.

Chapter Summary and Key Terms

THE ATOMIC THEORY OF MATTER; THE DISCOVERY OF ATOMIC STRUCTURE (SECTIONS 2.1 AND 2.2) Atoms are the basic building blocks of matter. They are the smallest units of an element that can combine with other elements. Atoms are composed of even smaller particles, called **subatomic particles**. Some of these subatomic particles are charged and follow the usual behavior of charged particles: Particles with the same charge repel one another, whereas particles with unlike charges are attracted to one another.

We considered some of the important experiments that led to the discovery and characterization of subatomic particles. Thomson's experiments on the behavior of **cathode rays** in magnetic and electric fields led to the discovery of the electron and allowed its charge-tomass ratio to be measured. Millikan's oil-drop experiment determined the charge of the electron. Becquerel's discovery of **radioactivity**, the spontaneous emission of radiation by atoms, gave further evidence that the atom has a substructure. Rutherford's studies of how thin metal foils scatter α particles led to the **nuclear model** of the atom, showing that the atom has a dense, positively charged **nucleus**.

THE MODERN VIEW OF ATOMIC STRUCTURE (SECTION 2.3)

Atoms have a nucleus that contains protons and neutrons; electrons move in the space around the nucleus. The magnitude of the charge of the electron, 1.602×10^{-19} C, is called the electronic charge. The charges of particles are usually represented as multiples of this charge—an electron has a 1– charge, and a proton has a 1+ charge. The masses of atoms are usually expressed in terms of atomic mass units (1 amu = 1.66054×10^{-24} g). The dimensions of atoms are often expressed in units of angstroms (1 Å = 10^{-10} m).

Elements can be classified by **atomic number**, the number of protons in the nucleus of an atom. All atoms of a given element have the same atomic number. The **mass number** of an atom is the sum of the numbers of protons and neutrons. Atoms of the same element that differ in mass number are known as **isotopes**.

ATOMIC WEIGHTS (SECTION 2.4) The atomic mass scale is defined by assigning a mass of exactly 12 amu to a ¹²C atom. The **atomic weight** (average atomic mass) of an element can be calculated from the relative abundances and masses of that element's isotopes. The **mass spectrometer** provides the most direct and accurate means of experimentally measuring atomic (and molecular) weights.

THE PERIODIC TABLE (SECTION 2.5) The **periodic table** is an arrangement of the elements in order of increasing atomic number. Elements with similar properties are placed in vertical columns. The elements in a column are known as a **group**. The elements in a horizontal row are known as a **period**. The **metallic elements (metals)**, which comprise the majority of the elements, dominate the left side and the middle of the table; the **nonmetallic elements (nonmetals)** are located on the upper right side. Many of the elements that lie along the line that separates metals from nonmetals are **metalloids**.

MOLECULES AND MOLECULAR COMPOUNDS (SECTION 2.6)

Atoms can combine to form molecules. Compounds composed of molecules (molecular compounds) usually contain only nonmetallic elements. A molecule that contains two atoms is called a diatomic molecule. The composition of a substance is given by its chemical formula. A molecular substance can be represented by its empirical formula, which gives the relative numbers of atoms of each kind. It is usually represented by its molecular formula, however, which gives the actual numbers of each type of atom in a molecule. Structural formulas show the order in which the atoms in a molecule are connected. Ball-and-stick models and space-filling models are often used to represent molecules.

IONS AND IONIC COMPOUNDS (SECTION 2.7) Atoms can either gain or lose electrons, forming charged particles called ions. Metals tend to lose electrons, becoming positively charged ions (cations). Nonmetals tend to gain electrons, forming negatively charged ions (anions). Because ionic compounds are electrically neutral, containing both cations and anions, they usually contain both metallic and nonmetallic elements. Atoms that are joined together, as in a molecule, but carry a net charge are called polyatomic ions. The chemical formulas used for ionic compounds are empirical formulas, which can be written readily if the charges of the ions are known. The total positive charge of the cations in an ionic compound equals the total negative charge of the anions.

NAMING INORGANIC COMPOUNDS (SECTION 2.8) The set of rules for naming chemical compounds is called **chemical nomenclature.** We studied the systematic rules used for naming three classes of inorganic substances: ionic compounds, acids, and binary molecular compounds. In naming an ionic compound, the cation is named first and then the anion. Cations formed from metal atoms have the same name as the metal. If the metal can form cations of differing charges, the charge is given using Roman numerals. Monatomic anions have names ending in *-ide*. Polyatomic anions containing oxygen and another element (**oxyanions**) have names ending in *-ate* or *-ite*.

SOME SIMPLE ORGANIC COMPOUNDS (SECTION 2.9) Organic chemistry is the study of compounds that contain carbon. The simplest class of organic molecules is the **hydrocarbons**, which contain only carbon and hydrogen. Hydrocarbons in which each carbon atom is attached to four other atoms are called **alkanes**. Alkanes have names that end in *-ane*, such as methane and ethane. Other organic compounds are formed when an H atom of a hydrocarbon is replaced with a functional group. An **alcohol**, for example, is a compound in which an H atom of a hydrocarbon is replaced by an OH functional group. Alcohols have names that end in *-ol*, such as methanol and ethanol. Compounds with the same molecular formula but different bonding arrangements of their constituent atoms are called **isomers**.

Learning Outcomes After studying this chapter, you should be able to:

- List the basic postulates of Dalton's atomic theory. (Section 2.1)
- Describe the key experiments that led to the discovery of electrons and to the nuclear model of the atom. (Section 2.2)
- Describe the structure of the atom in terms of protons, neutrons, and electrons. (Section 2.3)
- Describe the electrical charge and relative masses of protons, neutrons, and electrons. (Section 2.3)
- Use chemical symbols together with atomic number and mass number to express the subatomic composition of isotopes. (Section 2.3)

- Calculate the atomic weight of an element from the masses of individual atoms and a knowledge of natural abundances. (Section 2.4)
- Describe how elements are organized in the periodic table by atomic number and by similarities in chemical behavior, giving rise to periods and groups. (Section 2.5)
- Identify the locations of metals and nonmetals in the periodic table. (Section 2.5)
- Distinguish between molecular substances and ionic substances in terms of their composition. (Sections 2.6 and 2.7)
- Distinguish between empirical formulas and molecular formulas. (Section 2.6)
- Describe how molecular formulas and structural formulas are used to represent the compositions of molecules. (Section 2.6)

- Explain how ions are formed by the gain or loss of electrons and be able to use the periodic table to predict the charges of common ions. (Section 2.7)
- Write the empirical formulas of ionic compounds, given the charges of their component ions. (Section 2.7)
- Write the name of an ionic compound given its chemical formula or write the chemical formula given its name. (Section 2.8)
- Name or write chemical formulas for binary inorganic compounds and for acids. (Section 2.8)
- Identify organic compounds and name simple alkanes and alcohols.
 (Section 2.9)

Key Equations

Atomic weight = \sum [(isotope mass) × (fractional isotope abundance)] over all isotopes of the element [2.1]

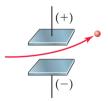

Calculating atomic weight as a fractionally weighted average of isotopic masses.

Exercises

Visualizing Concepts

These exercises are intended to probe your understanding of key concepts rather than your ability to utilize formulas and perform calculations. Exercises with red numbers have answers in the back of the book.

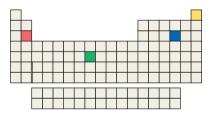

2.1 A charged particle is caused to move between two electrically charged plates, as shown here.

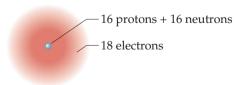

- (a) Why does the path of the charged particle bend? (b) What is the sign of the electrical charge on the particle? (c) As the charge on the plates is increased, would you expect the bending to increase, decrease, or stay the same? (d) As the mass of the particle is increased while the speed of the particles remains the same, would you expect the bending to increase, decrease, or stay the same? [Section 2.2]
- 2.2 The following diagram is a representation of 20 atoms of a fictitious element, which we will call nevadium (Nv). The red spheres are ²⁹³Nv, and the blue spheres are ²⁹⁵Nv. (a) Assuming that this sample is a statistically representative sample of the element, calculate the percent abundance of each element. (b) If the mass of ²⁹³Nv is 293.15 amu and that of ²⁹⁵Nv is 295.15 amu, what is the atomic weight of Nv? [Section 2.4]

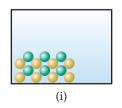

2.3 Four of the boxes in the following periodic table are colored. Which of these are metals and which are nonmetals? Which one is an alkaline earth metal? Which one is a noble gas? [Section 2.5]

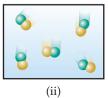

2.4 Does the following drawing represent a neutral atom or an ion? Write its complete chemical symbol including mass number, atomic number, and net charge (if any). [Sections 2.3 and 2.7]

2.5 Which of the following diagrams most likely represents an ionic compound, and which represents a molecular one? Explain your choice. [Sections 2.6 and 2.7]

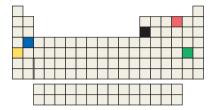

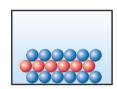

2.6 Write the chemical formula for the following compound. Is the compound ionic or molecular? Name the compound. [Sections 2.6 and 2.8]

2.7 Five of the boxes in the following periodic table are colored. Predict the charge on the ion associated with each of these elements. [Section 2.7]

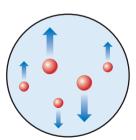

2.8 The following diagram represents an ionic compound in which the red spheres represent cations and blue spheres represent anions. Which of the following formulas is consistent with the drawing? KBr, K₂SO₄, Ca(NO₃)₂, Fe₂(SO₄)₃. Name the compound. [Sections 2.7 and 2.8]

2.9 Are these two compounds isomers? Explain. [Section 2.9]

2.10 In the Millikan oil-drop experiment (see Figure 2.5) the tiny oil drops are observed through the viewing lens as rising, stationary, or falling, as shown here. (a) What causes their rate of fall to vary from their rate in the absence of an electric field? (b) Why do some drops move upward? [Section 2.2]

The following exercises are divided into sections that deal with specific topics in the chapter. The exercises are grouped in pairs, with the answers given in the back of the book to the odd-numbered exercises, as indicated by the red exercise numbers. Those exercises whose numbers appear in brackets are more challenging than the nonbracketed exercises.

The Atomic Theory of Matter and the Discovery of Atomic Structure (Sections 2.1 and 2.2)

- 2.11 How does Dalton's atomic theory account for the fact that when 1.000 g of water is decomposed into its elements, 0.111 g of hydrogen and 0.889 g of oxygen are obtained regardless of the source of the water?
- 2.12 Hydrogen sulfide is composed of two elements: hydrogen and sulfur. In an experiment, 6.500 g of hydrogen sulfide is fully decomposed into its elements. (a) If 0.384 g of hydrogen is obtained in this experiment, how many grams of sulfur must be obtained? (b) What fundamental law does this experiment demonstrate? (c) How is this law explained by Dalton's atomic theory?
- 2.13 A chemist finds that 30.82 g of nitrogen will react with 17.60, 35.20, 70.40, or 88.00 g of oxygen to form four different compounds. (a) Calculate the mass of oxygen per gram of nitrogen in each compound. (b) How do the numbers in part (a) support Dalton's atomic theory?
- 2.14 In a series of experiments, a chemist prepared three different compounds that contain only iodine and fluorine and determined the mass of each element in each compound:

Compound	Mass of Iodine (g)	Mass of Fluorine (g)
1	4.75	3.56
2	7.64	3.43
3	9.41	9.86

- (a) Calculate the mass of fluorine per gram of iodine in each compound. (b) How do the numbers in part (a) support the atomic theory?
- **2.15** Summarize the evidence used by J. J. Thomson to argue that cathode rays consist of negatively charged particles.
- 2.16 An unknown particle is caused to move between two electrically charged plates, as illustrated in Figure 2.8. Its path is deflected by a smaller magnitude in the opposite direction from that of a beta particle. What can you conclude about the charge and mass of this unknown particle?
- **2.17** How did Rutherford interpret the following observations made during his α -particle scattering experiments? (a) Most α particles were not appreciably deflected as they passed through the gold foil. (b) A few α particles were deflected at very large angles. (c) What differences would you expect if beryllium foil were used instead of gold foil in the α -particle scattering experiment?
- 2.18 Millikan determined the charge on the electron by studying the static charges on oil drops falling in an electric field (Figure 2.5). A student carried out this experiment using several oil drops for her measurements and calculated the charges on the drops. She obtained the following data:

Droplet	Calculated Charge (C)
A	1.60×10^{-19}
В	3.15×10^{-19}
С	4.81×10^{-19}
D	6.31×10^{-19}

(a) What is the significance of the fact that the droplets carried different charges? (b) What conclusion can the student draw from these data regarding the charge of the electron?(c) What value (and to how many significant figures) should she report for the electronic charge?

The Modern View of Atomic Structure; Atomic Weights (Sections 2.3 and 2.4)

- 2.19 The radius of an atom of gold (Au) is about 1.35 Å. (a) Express this distance in nanometers (nm) and in picometers (pm).
 (b) How many gold atoms would have to be lined up to span 1.0 mm? (c) If the atom is assumed to be a sphere, what is the volume in cm³ of a single Au atom?
- **2.20** An atom of rhodium (Rh) has a diameter of about 2.7×10^{-8} cm. (a) What is the radius of a rhodium atom in angstroms (Å) and in meters (m)? (b) How many Rh atoms would have to be placed side by side to span a distance of $6.0 \,\mu\text{m}$? (c) If you assume that the Rh atom is a sphere, what is the volume in m³ of a single atom?
- 2.21 Answer the following questions without referring to Table 2.1:(a) What are the main subatomic particles that make up the atom? (b) What is the relative charge (in multiples of the electronic charge) of each of the particles? (c) Which of the particles is the most massive? (d) Which is the least massive?
- 2.22 Determine whether each of the following statements is true or false. If false, correct the statement to make it true: (a) The nucleus has most of the mass and comprises most of the volume of an atom. (b) Every atom of a given element has the same number of protons. (c) The number of electrons in an atom equals the number of neutrons in the atom. (d) The protons in the nucleus of the helium atom are held together by a force called the strong nuclear force.
- **2.23** Which of the following pairs of atoms are isotopes of one another? (a) 11 B, 11 C; (b) 55 Mn, 54 Mn; (c) 50 Sn, 120 Sn
- **2.24** What are the differences in the compositions of the following pairs of atomic nuclei? (a) $^{210}_{83}$ Bi, $^{210}_{82}$ Pb; (b) $^{14}_{7}$ N, $^{15}_{7}$ N; (c) $^{10}_{10}$ Ne, $^{40}_{18}$ Ar
- **2.25** (a) Define atomic number and mass number. (b) Which of these can vary without changing the identity of the element?
- **2.26** (a) Which two of the following are isotopes of the same element: ${}_{16}^{31}$ X, ${}_{15}^{31}$ X, ${}_{16}^{32}$ X? (b) What is the identity of the element whose isotopes you have selected?
- 2.27 How many protons, neutrons, and electrons are in the following atoms? (a) 40 Ar, (b) 65 Zn, (c) 70 Ga, (d) 80 Br, (e) 184 W, (f) 243 Am.
- 2.28 Each of the following isotopes is used in medicine. Indicate the number of protons and neutrons in each isotope:
 (a) phosphorus-32, (b) chromium-51, (c) cobalt-60, (d) technetium-99, (e) iodine-131, (f) thallium-201.
- **2.29** Fill in the gaps in the following table, assuming each column represents a neutral atom.

Symbol	⁷⁹ Br				
Protons		25			82
Neutrons		30	64		
Electrons			48	86	
Mass no.				222	207

2.30 Fill in the gaps in the following table, assuming each column represents a neutral atom.

Symbol	¹¹² Cd				
Protons		38			92
Neutrons		58	49		
Electrons			38	36	
Mass no.				81	235

- 2.31 Write the correct symbol, with both superscript and subscript, for each of the following. Use the list of elements in the front inside cover as needed: (a) the isotope of platinum that contains 118 neutrons, (b) the isotope of krypton with mass number 84, (c) the isotope of arsenic with mass number 75, (d) the isotope of magnesium that has an equal number of protons and neutrons.
- 2.32 One way in which Earth's evolution as a planet can be understood is by measuring the amounts of certain isotopes in rocks. One quantity recently measured is the ratio of ¹²⁹Xe to ¹³⁰Xe in some minerals. In what way do these two isotopes differ from one another? In what respects are they the same?
- **2.33** (a) What isotope is used as the standard in establishing the atomic mass scale? (b) The atomic weight of boron is reported as 10.81, yet no atom of boron has the mass of 10.81 amu. Explain.
- 2.34 (a) What is the mass in amu of a carbon-12 atom? (b) Why is the atomic weight of carbon reported as 12.011 in the table of elements and the periodic table in the front inside cover of this text?
- **2.35** Only two isotopes of copper occur naturally, ⁶³Cu (atomic mass = 62.9296 amu; abundance 69.17%) and ⁶⁵Cu (atomic mass = 64.9278 amu; abundance 30.83%). Calculate the atomic weight (average atomic mass) of copper.
- **2.36** Rubidium has two naturally occurring isotopes, rubidium-85 (atomic mass = 84.9118 amu; abundance = 72.15%) and rubidium-87 (atomic mass = 86.9092 amu; abundance = 27.85%). Calculate the atomic weight of rubidium.
- 2.37 (a) Thomson's cathode–ray tube (Figure 2.4) and the mass spectrometer (Figure 2.11) both involve the use of electric or magnetic fields to deflect charged particles. What are the charged particles involved in each of these experiments? (b) What are the labels on the axes of a mass spectrum? (c) To measure the mass spectrum of an atom, the atom must first lose one or more electrons. Which would you expect to be deflected more by the same setting of the electric and magnetic fields, a Cl⁺ or a Cl²⁺ ion?
- **2.38** (a) The mass spectrometer in Figure 2.11 has a magnet as one of its components. What is the purpose of the magnet? (b) The atomic weight of Cl is 35.5 amu. However, the mass spectrum of Cl (Figure 2.12) does not show a peak at this mass. Explain. (c) A mass spectrum of phosphorus (P) atoms shows only a single peak at a mass of 31. What can you conclude from this observation?
- 2.39 Naturally occurring magnesium has the following isotopic abundances:

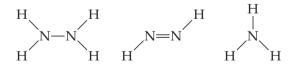

Isotope	Abundance (%)	Atomic mass (amu)
24 Mg	78.99	23.98504
25 Mg	10.00	24.98584
²⁶ Mg	11.01	25.98259

(a) What is the average atomic mass of Mg? (b) Sketch the mass spectrum of Mg.

2.40 Mass spectrometry is more often applied to molecules than to atoms. We will see in Chapter 3 that the *molecular weight* of a molecule is the sum of the atomic weights of the atoms in the molecule. The mass spectrum of H₂ is taken under conditions that prevent decomposition into H atoms. The two naturally occurring isotopes of hydrogen are ¹H (atomic mass = 1.00783 amu; abundance 99.9885%) and ²H (atomic mass = 2.01410 amu; abundance 0.0115%). (a) How many peaks will the mass spectrum have? (b) Give the relative atomic masses of each of these peaks. (c) Which peak will be the largest, and which the smallest?

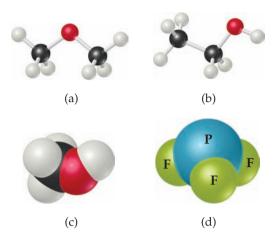

The Periodic Table, Molecules and Molecular Compounds, and Ions and Ionic Compounds (Sections 2.5 and 2.7)

- 2.41 For each of the following elements, write its chemical symbol, locate it in the periodic table, give its atomic number, and indicate whether it is a metal, metalloid, or nonmetal:(a) chromium, (b) helium, (c) phosphorus, (d) zinc, (e) magnesium, (f) bromine, (g) arsenic.
- 2.42 Locate each of the following elements in the periodic table; give its name and atomic number, and indicate whether it is a metal, metalloid, or nonmetal: (a) Li, (b) Sc, (c) Ge, (d) Yb, (e) Mn, (f) Sb, (g) Xe.
- 2.43 For each of the following elements, write its chemical symbol, determine the name of the group to which it belongs (Table 2.3), and indicate whether it is a metal, metalloid, or nonmetal: (a) potassium, (b) iodine, (c) magnesium, (d) argon, (e) sulfur.
- 2.44 The elements of group 4A show an interesting change in properties moving down the group. Give the name and chemical symbol of each element in the group and label it as a nonmetal, metalloid, or metal.
- 2.45 What can we tell about a compound when we know the empirical formula? What additional information is conveyed by the molecular formula? By the structural formula? Explain in each case.
- **2.46** Two compounds have the same empirical formula. One substance is a gas, whereas the other is a viscous liquid. How is it possible for two substances with the same empirical formula to have markedly different properties?
- 2.47 What are the molecular and empirical formulas for each of the following compounds?

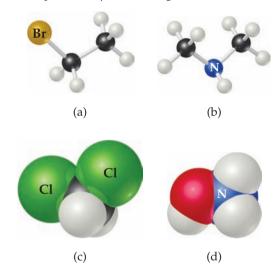

- **2.48** Two substances have the same molecular and empirical formulas. Does this mean that they must be the same compound?
- **2.49** Write the empirical formula corresponding to each of the following molecular formulas: (a) Al_2Br_6 , (b) C_8H_{10} , (c) $C_4H_8O_2$, (d) P_4O_{10} , (e) $C_6H_4Cl_2$, (f) $B_3N_3H_6$.
- 2.50 Determine the molecular and empirical formulas of the following: (a) the organic solvent benzene, which has six carbon atoms and six hydrogen atoms; (b) the compound silicon tetrachloride, which has a silicon atom and four chlorine atoms and is used in the manufacture of computer chips; (c) the reactive substance diborane, which has two boron atoms and six hydrogen atoms; (d) the sugar called glucose, which has six carbon atoms, twelve hydrogen atoms, and six oxygen atoms.
- **2.51** How many hydrogen atoms are in each of the following: (a) C_2H_5OH , (b) $Ca(C_2H_5COO)_2$, (c) $(NH_4)_3PO_4$?

- 2.52 How many of the indicated atoms are represented by each chemical formula: (a) carbon atoms in C₄H₈COOCH₃, (b) oxygen atoms in Ca(ClO₃)₂, (c) hydrogen atoms in (NH₄)₂HPO₄?
- **2.53** Write the molecular and structural formulas for the compounds represented by the following molecular models:

2.54 Write the molecular and structural formulas for the compounds represented by the following models:

2.55 Fill in the gaps in the following table:

Symbol	⁵⁹ Co ³⁺			
Protons		34	76	80
Neutrons		46	116	120
Electrons		36		78
Net charge			2+	

2.56 Fill in the gaps in the following table:

Symbol	$^{31}P^{3-}$			
Protons		34	50	
Neutrons		45	69	118
Electrons			46	76
Net charge		2-		3+

2.57 Each of the following elements is capable of forming an ion in chemical reactions. By referring to the periodic table, predict the charge of the most stable ion of each: (a) Mg, (b) Al, (c) K, (d) S, (e) F.

- **2.58** Using the periodic table, predict the charges of the ions of the following elements: (a) Ga, (b) Sr, (c) As, (d) Br, (e) Se.
- **2.59** Using the periodic table to guide you, predict the chemical formula and name of the compound formed by the following elements: (a) Ga and F, (b) Li and H, (c) Al and I, (d) K and S.
- 2.60 The most common charge associated with scandium in its compounds is 3+. Indicate the chemical formulas you would expect for compounds formed between scandium and (a) iodine, (b) sulfur, (c) nitrogen.
- **2.61** Predict the chemical formula for the ionic compound formed by (a) Ca^{2+} and Br^{-} , (b) K^{+} and CO_{3}^{2-} , (c) Al^{3+} and $CH_{3}COO^{-}$, (d) NH_{4}^{+} and SO_{4}^{2-} , (e) Mg^{2+} and PO_{4}^{3-} .
- **2.62** Predict the chemical formulas of the compounds formed by the following pairs of ions: (a) Cr³⁺ and Br⁻, (b) Fe³⁺ and O²⁻, (c) Hg₂²⁺ and CO₃²⁻, (d) Ca²⁺ and ClO₃⁻, (e) NH₄⁺ and PO₄³⁻.
- 2.63 Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

Ion	K ⁺	NH ₄ ⁺	Mg ²⁺	Fe ³⁺
Cl ⁻	KCl			
OH^-				
CO_3^{2-}				
$PO_4^{\ 3-}$				

2.64 Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

Ion	Na ⁺	Ca ²⁺	Fe ²⁺	Al ³⁺
O^{2-}	Na ₂ O			
NO_3^-				
SO_4^{2-}				
AsO ₄ ³⁻				

- **2.65** Predict whether each of the following compounds is molecular or ionic: (a) B₂H₆, (b) CH₃OH, (c) LiNO₃, (d) Sc₂O₃, (e) CsBr, (f) NOCl, (g) NF₃, (h) Ag₂SO₄.
- 2.66 Which of the following are ionic, and which are molecular?
 (a) PF₅, (b) NaI, (c) SCl₂, (d) Ca(NO₃)₂, (e) FeCl₃, (f) LaP,
 (g) CoCO₃, (h) N₂O₄.

Naming Inorganic Compounds; Some Simple Organic Compounds (Sections 2.8 and 2.9)

- **2.67** Give the chemical formula for (a) chlorite ion, (b) chloride ion, (c) chlorate ion, (d) perchlorate ion, (e) hypoite ion.
- **2.68** Selenium, an element required nutritionally in trace quantities, forms compounds analogous to sulfur. Name the following ions: (a) SeO_4^{2-} , (b) Se^{2-} , (c) HSe^- , (d) $HSeO_3^-$.
- **2.69** Give the names and charges of the cation and anion in each of the following compounds: (a) CaO, (b) Na₂SO₄, (c) KClO₄, (d) Fe(NO₃)₂, (e) Cr(OH)₃.
- 2.70 Give the names and charges of the cation and anion in each of the following compounds: (a) CuS, (b) Ag₂SO₄, (c) Al(ClO₃)₃, (d) Co(OH)₂, (e) PbCO₃.
- **2.71** Name the following ionic compounds: (a) Li₂O, (b) FeCl₃, (c) NaClO, (d) CaSO₃, (e) Cu(OH)₂, (f) Fe(NO₃)₂, (g) Ca(CH₃COO)₂, (h) Cr₂(CO₃)₃, (i) K₂CrO₄, (j) (NH₄)₂SO₄.

- 2.72 Name the following ionic compounds: (a) KCN, (b) NaBrO₂,
 (c) Sr(OH)₂, (d) CoTe, (e) Fe₂(CO₃)₃, (f) Cr(NO₃)₃,
 (g) (NH₄)₂SO₃, (h) NaH₂PO₄, (i) KMnO₄, (j) Ag₂Cr₂O₇.
- **2.73** Write the chemical formulas for the following compounds: (a) aluminum hydroxide, (b) potassium sulfate, (c) copper(I) oxide, (d) zinc nitrate, (e) mercury(II) bromide, (f) iron(III) carbonate, (g) sodium hypobromite.
- **2.74** Give the chemical formula for each of the following ionic compounds: (a) sodium phosphate, (b) zinc nitrate, (c) barium bromate, (d) iron(II) perchlorate, (e) cobalt(II) hydrogen carbonate, (f) chromium(III) acetate, (g) potassium dichromate.
- **2.75** Give the name or chemical formula, as appropriate, for each of the following acids: (a) HBrO₃, (b) HBr, (c) H₃PO₄, (d) hypochlorous acid, (e) iodic acid, (f) sulfurous acid.
- **2.76** Provide the name or chemical formula, as appropriate, for each of the following acids: (a) hydroiodic acid, (b) chloric acid, (c) nitrous acid, (d) H₂CO₃, (e) HClO₄, (f) CH₃COOH.
- 2.77 Give the name or chemical formula, as appropriate, for each of the following binary molecular substances: (a) SF₆, (b) IF₅, (c) XeO₃, (d) dinitrogen tetroxide, (e) hydrogen cyanide, (f) tetraphosphorus hexasulfide.
- 2.78 The oxides of nitrogen are very important components in urban air pollution. Name each of the following compounds:(a) N₂O, (b) NO, (c) NO₂, (d) N₂O₅, (e) N₂O₄.
- 2.79 Write the chemical formula for each substance mentioned in the following word descriptions (use the front inside cover to find the symbols for the elements you do not know). (a) Zinc carbonate can be heated to form zinc oxide and carbon dioxide. (b) On treatment with hydrofluoric acid, silicon dioxide forms silicon tetrafluoride and water. (c) Sulfur dioxide reacts with water to form sulfurous acid. (d) The substance phosphorus trihydride, commonly called phosphine, is a toxic gas. (e) Perchloric acid reacts with cadmium to form cadmium(II) perchlorate. (f) Vanadium(III) bromide is a colored solid.
- 2.80 Assume that you encounter the following sentences in your reading. What is the chemical formula for each substance mentioned? (a) Sodium hydrogen carbonate is used as a deodorant.
 (b) Calcium hypochlorite is used in some bleaching solutions.
 (c) Hydrogen cyanide is a very poisonous gas. (d) Magnesium hydroxide is used as a cathartic. (e) Tin(II) fluoride has been used as a fluoride additive in toothpastes. (f) When cadmium sulfide is treated with sulfuric acid, fumes of hydrogen sulfide are given off.
- **2.81** (a) What is a hydrocarbon? (b) Pentane is the alkane with a chain of five carbon atoms. Write a structural formula for this compound and determine its molecular and empirical formulas.
- **2.82** (a) What is meant by the term *isomer*? (b) Among the four alkanes, ethane, propane, butane, and pentane, which is capable of existing in isomeric forms?
- **2.83** (a) What is a functional group? (b) What functional group characterizes an alcohol? (c) Write a structural formula for 1-pentanol, the alcohol derived from pentane by making a substitution on one of the carbon atoms.
- **2.84** (a) What do ethane and ethanol have in common? (b) How does 1-propanol differ from propane?
- **2.85** Chloropropane is derived from propane by substituting Cl for H on one of the carbon atoms. (a) Draw the structural formulas for the two isomers of chloropropane. (b) Suggest names for these two compounds.
- **2.86** Draw the structural formulas for three isomers of pentane, C_5H_{12} .

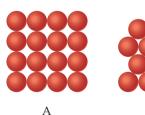

Additional Exercises

These exercises are not divided by category, although they are roughly in the order of the topics in the chapter. They are not paired.

2.87 Suppose a scientist repeats the Millikan oil-drop experiment but reports the charges on the drops using an unusual (and imaginary) unit called the *warmomb* (wa). The scientist obtains the following data for four of the drops:

Droplet	Calculated Charge (wa)
A	3.84×10^{-8}
В	4.80×10^{-8}
С	2.88×10^{-8}
D	8.64×10^{-8}

- (a) If all the droplets were the same size, which would fall most slowly through the apparatus?
 (b) From these data, what is the best choice for the charge of the electron in warmombs?
 (c) Based on your answer to part (b), how many electrons are there on each of the droplets?
 (d) What is the conversion factor between warmombs and coulombs?
- 2.88 The natural abundance of ³He is 0.000137%. (a) How many protons, neutrons, and electrons are in an atom of ³He? (b) Based on the sum of the masses of their subatomic particles, which is expected to be more massive, an atom of ³He or an atom of ³H (which is also called *tritium*)? (c) Based on your answer to part (b), what would need to be the precision of a mass spectrometer that is able to differentiate between peaks that are due to ³He⁺ and ³H⁺?
- 2.89 A cube of gold that is 1.00 cm on a side has a mass of 19.3 g. A single gold atom has a mass of 197.0 amu. (a) How many gold atoms are in the cube? (b) From the information given, estimate the diameter in Å of a single gold atom. (c) What assumptions did you make in arriving at your answer for part (b)?
- 2.90 The diameter of a rubidium atom is 4.95 Å. We will consider two different ways of placing the atoms on a surface. In arrangement A, all the atoms are lined up with one another to form a square grid. Arrangement B is called a *close-packed* arrangement because the atoms sit in the "depressions" formed by the previous row of atoms:

(a) Using arrangement A, how many Rb atoms could be placed on a square surface that is 1.0 cm on a side? (b) How many Rb atoms could be placed on a square surface that is 1.0 cm on a side, using arrangement B? (c) By what factor has the number of atoms on the surface increased in going to arrangement B from arrangement A? If extended to three dimensions, which arrangement would lead to a greater density for Rb metal?

В

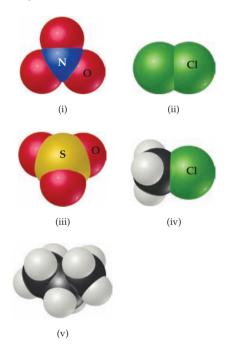

2.91 (a) Assuming the dimensions of the nucleus and atom shown in Figure 2.11, what fraction of the *volume* of the atom is taken up by the nucleus? (b) Using the mass of the proton from Table 2.1 and assuming its diameter is 1.0×10^{-15} m, calculate the density of a proton in g/cm³.

- **2.92** Identify the element represented by each of the following symbols and give the number of protons and neutrons in each: (a) $_{33}^{74}$ X, (b) $_{53}^{127}$ X, (c) $_{63}^{152}$ X, (d) $_{83}^{209}$ X.
- 2.93 The nucleus of ⁶Li is a powerful absorber of neutrons. It exists in the naturally occurring metal to the extent of 7.5%. In the era of nuclear deterrence, large quantities of lithium were processed to remove ⁶Li for use in hydrogen bomb production. The lithium metal remaining after removal of ⁶Li was sold on the market. (a) What are the compositions of the nuclei of ⁶Li and ⁷Li? (b) The atomic masses of ⁶Li and ⁷Li are 6.015122 and 7.016004 amu, respectively. A sample of lithium depleted in the lighter isotope was found on analysis to contain 1.442% ⁶Li. What is the average atomic weight of this sample of the metal?
- 2.94 The element oxygen has three naturally occurring isotopes, with 8, 9, and 10 neutrons in the nucleus, respectively.(a) Write the full chemical symbols for these three isotopes.(b) Describe the similarities and differences between the three kinds of atoms of oxygen.
- 2.95 The element lead (Pb) consists of four naturally occurring isotopes with atomic masses 203.97302, 205.97444, 206.97587, and 207.97663 amu. The relative abundances of these four isotopes are 1.4, 24.1, 22.1, and 52.4% respectively. From these data, calculate the atomic weight of lead.
- **2.96** Gallium (Ga) consists of two naturally occurring isotopes with masses of 68.926 and 70.925 amu. (a) How many protons and neutrons are in the nucleus of each isotope? Write the complete atomic symbol for each, showing the atomic number and mass number. (b) The average atomic mass of Ga is 69.72 amu. Calculate the abundance of each isotope.
- 2.97 Using a suitable reference such as the CRC Handbook of Chemistry and Physics or http://www.webelements.com, look up the following information for nickel: (a) the number of known isotopes, (b) the atomic masses (in amu), (c) the natural abundances of the five most abundant isotopes.
- **2.98** There are two different isotopes of bromine atoms. Under normal conditions, elemental bromine consists of Br_2 molecules, and the mass of a Br_2 molecule is the sum of the masses of the two atoms in the molecule. The mass spectrum of Br_2 consists of three peaks:

Mass (amu)	Relative Size
157.836	0.2569
159.834	0.4999
161.832	0.2431

- (a) What is the origin of each peak (of what isotopes does each consist)? (b) What is the mass of each isotope? (c) Determine the average molecular mass of a Br_2 molecule. (d) Determine the average atomic mass of a bromine atom. (e) Calculate the abundances of the two isotopes.
- 2.99 It is common in mass spectrometry to assume that the mass of a cation is the same as that of its parent atom. (a) Using data in Table 2.1, determine the number of significant figures that must be reported before the difference in masses of ¹H and ¹H⁺ is significant. (b) What percentage of the mass of an ¹H atom does the electron represent?
- **2.100** From the following list of elements—Ar, H, Ga, Al, Ca, Br, Ge, K, O—pick the one that best fits each description. Use each element only once: (a) an alkali metal, (b) an alkaline

- earth metal, (c) a noble gas, (d) a halogen, (e) a metalloid, (f) a nonmetal listed in group 1A, (g) a metal that forms a 3+ ion, (h) a nonmetal that forms a 2- ion, (i) an element that resembles aluminum.
- 2.101 The first atoms of seaborgium (Sg) were identified in 1974. The longest-lived isotope of Sg has a mass number of 266.
 (a) How many protons, electrons, and neutrons are in an ²⁶⁶Sg atom? (b) Atoms of Sg are very unstable, and it is therefore difficult to study this element's properties. Based on the position of Sg in the periodic table, what element should it most closely resemble in its chemical properties?
- **2.102** The explosion of an atomic bomb releases many radioactive isotopes, including strontium-90. Considering the location of strontium in the periodic table, suggest a reason for the fact that this isotope is particularly dangerous for human health.
- **2.103** From the molecular structures shown here, identify the one that corresponds to each of the following species: (a) chlorine gas; (b) propane; (c) nitrate ion; (d) sulfur trioxide; (e) methyl chloride, CH₃Cl.

- 2.104 Name each of the following oxides. Assuming that the compounds are ionic, what charge is associated with the metallic element in each case? (a) NiO, (b) MnO_2 , (c) Cr_2O_3 , (d) MoO_3 .
- **2.105** Fill in the blanks in the following table:

Cation	Anion	Formula	Name
			Lithium oxide
Fe^{2+}	PO ₄ ³⁻		
		$Al_2(SO_4)_3$	

Cation	Anion	Formula	Name
			Copper(II) nitrate
Cr ³⁺	I_		
		MnClO ₂	
			Ammonium carbonate
			Zinc perchlorate

2.106 Cyclopropane is an interesting hydrocarbon. Instead of having three carbons in a row, the three carbons form a ring, as shown in this perspective drawing (see Figure 2.17 for a prior example of this kind of drawing):

Cyclopropane was at one time used as an anesthetic, but its use was discontinued, in part because it is highly inflammable.

- (a) What is the empirical formula of cyclopropane? How does it differ from that of propane? (b) The three carbon atoms are necessarily in a plane. What do the different wedges mean? (c) What change would you make to the structure shown to illustrate chlorocyclopropane? Are there isomers of chlorocyclopropane?
- 2.107 Elements in the same group of the periodic table often form oxyanions with the same general formula. The anions are also named in a similar fashion. Based on these observations, suggest a chemical formula or name, as appropriate, for each of the following ions:

 (a) BrO₄⁻
 (b) SeO₃²⁻
 (c) arsenate ion
 (d) hydrogen tellurate ion
- 2.108 Carbonic acid occurs in carbonated beverages. When allowed to react with lithium hydroxide, it produces lithium carbonate. Lithium carbonate is used to treat depression and bipolar disorder. Write chemical formulas for carbonic acid, lithium hydroxide, and lithium carbonate.
- 2.109 Give the chemical names of each of the following familiar compounds: (a) NaCl (table salt), (b) NaHCO₃ (baking soda),
 (c) NaOCl (in many bleaches), (d) NaOH (caustic soda),
 (e) (NH₄)₂CO₃ (smelling salts), (f) CaSO₄ (plaster of Paris).
- 2.110 Many familiar substances have common, unsystematic names. For each of the following, give the correct systematic name:
 (a) saltpeter, KNO₃; (b) soda ash, Na₂CO₃; (c) lime, CaO;
 (d) muriatic acid, HCl; (e) Epsom salts, MgSO₄; (f) milk of magnesia, Mg(OH)₂.
- 2.111 Because many ions and compounds have very similar names, there is great potential for confusing them. Write the correct chemical formulas to distinguish between (a) calcium sulfide and calcium hydrogen sulfide, (b) hydrobromic acid and bromic acid, (c) aluminum nitride and aluminum nitrite, (d) iron(II) oxide and iron(III) oxide, (e) ammonia and ammonium ion, (f) potassium sulfite and potassium bisulfite, (g) mercurous chloride and mercuric chloride, (h) chloric acid and perchloric acid.
- **2.112** In what part of the atom does the strong nuclear force operate?

Chemical Reactions and Reaction Stoichiometry

Have you ever poured vinegar into a vessel containing baking soda? If so, you know the result is an immediate and effervescent cascade of bubbles. The bubbles contain carbon dioxide gas that is produced by the chemical reaction between sodium bicarbonate in the baking soda and acetic acid in the vinegar.

The bubbles released when baking soda reacts with an acid play an important role in baking, where the release of gaseous CO_2 causes the dough in your biscuits or the batter in your pancakes to rise. An alternative way to produce CO_2 in cooking is to use yeasts that rely on chemical reactions to convert sugar into CO_2 , ethanol, and other organic compounds. These types of chemical reactions have been used for thousands of years in the baking of breads as well as in the production of alcoholic beverages like beer and wine. Chemical reactions that produce CO_2 are not limited to cooking, though—they occur in places as diverse as the cells in your body and the engine of your car.

In this chapter we explore some important aspects of chemical reactions. Our focus will be both on the use of chemical formulas to represent reactions and on the quantitative information we can obtain about the amounts of substances involved in those reactions. **Stoichiometry** (pronounced stoy-key-OM-uh-tree) is the area of study that examines the quantities of substances consumed and produced in chemical reactions. Stoichiometry (Greek *stoicheion*, "element," and *metron*, "measure") provides an essential set of tools widely used in chemistry, including such diverse applications as measuring ozone concentrations in the atmosphere and assessing different processes for converting coal into gaseous fuels.

▶ THE TEXTURE AND FLAVORS of bread and beer are dependent on chemical reactions that occur when yeasts ferment sugars to produce carbon dioxide and ethanol.

- **3.1 CHEMICAL EQUATIONS** We begin by considering how we can use chemical formulas to write equations representing chemical reactions.
- **3.2 SIMPLE PATTERNS OF CHEMICAL REACTIVITY** We then examine some simple chemical reactions: *combination reactions*, *decomposition reactions*, and *combustion reactions*.
- 3.3 FORMULA WEIGHTS We see how to obtain quantitative information from chemical formulas by using *formula weights*.
- **3.4** AVOGADRO'S NUMBER AND THE MOLE We use chemical formulas to relate the masses of substances to the numbers of atoms, molecules, or ions contained in the substances, a relationship that leads to the crucially important concept of the *mole*, defined as 6.022×10^{23} objects (atoms, molecules, ions, and so on).
- **3.5 EMPIRICAL FORMULAS FROM ANALYSES** We apply the mole concept to determine chemical formulas from the masses of each element in a given quantity of a compound.

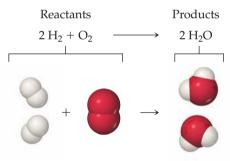

3.6 QUANTITATIVE INFORMATION FROM BALANCED EQUATIONS We use the quantitative information inherent in chemical formulas and equations together with the mole concept to predict the amounts of substances consumed or produced in chemical reactions.

3.7 LIMITING REACTANTS We recognize that one reactant may be used up before others in a chemical reaction. This is the *limiting reactant*. When this happens the reaction stops, leaving some excess of the other starting materials.

▲ Figure 3.1 Antoine Lavoisier (1734–1794). The science career of Lavoisier, who conducted many important studies on combustion reactions, was cut short by the French Revolution. Guillotined in 1794 during the Reign of Terror, he is generally considered the father of modern chemistry because he conducted carefully controlled experiments and used quantitative measurements.

▲ Figure 3.2 A balanced chemical equation.

Stoichiometry is built on an understanding of atomic masses (Section 2.4), chemical formulas, and the **law of conservation of mass**. (Section 2.1) The French nobleman and scientist Antoine Lavoisier (Figure 3.1) discovered this important chemical law during the late 1700s. Lavoisier stated the law in this eloquent way: "We may lay it down as an incontestable axiom that, in all the operations of art and nature, nothing is created; an equal quantity of matter exists both before and after the experiment. Upon this principle, the whole art of performing chemical experiments depends."* With the advent of Dalton's atomic theory, chemists came to understand the basis for this law: *Atoms are neither created nor destroyed during a chemical reaction*. The changes that occur during any reaction merely rearrange the atoms. The same collection of atoms is present both before and after the reaction.

3.1 | Chemical Equations

We represent chemical reactions by **chemical equations**. When the gas hydrogen (H_2) burns, for example, it reacts with oxygen (O_2) in the air to form water (H_2O) . We write the chemical equation for this reaction as

$$2 H_2 + O_2 \longrightarrow 2 H_2O$$
 [3.1]

We read the + sign as "reacts with" and the arrow as "produces." The chemical formulas to the left of the arrow represent the starting substances, called **reactants**. The chemical formulas to the right of the arrow represent substances produced in the reaction, called **products**. The numbers in front of the formulas, called coefficients, indicate the relative numbers of molecules of each kind involved in the reaction. (As in algebraic equations, *the coefficient 1 is usually not written*.)

Because atoms are neither created nor destroyed in any reaction, a chemical equation must have an equal number of atoms of each element on each side of the arrow. When this condition is met, the equation is *balanced*. On the right side of Equation 3.1, for example, there are two molecules of H_2O , each composed of two atoms of hydrogen and one atom of oxygen (\P Figure 3.2). Thus, $2 H_2O$ (read "two molecules of water") contains $2 \times 2 = 4 H$ atoms and $2 \times 1 = 2 O$ atoms. Notice that *the number of atoms is obtained by multiplying each subscript in a chemical formula by the coefficient for the formula*. Because there are four H atoms and two O atoms on each side of the equation, the equation is balanced.

Give It Some Thought

How many atoms of Mg, O, and H are represented by the notation 3 Mg(OH)₂?

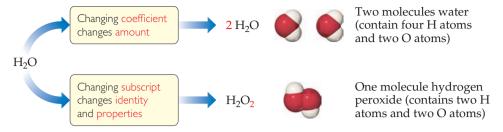

Balancing Equations

To construct a balanced chemical equation we start by writing the formulas for the reactants on the left–hand side of the arrow and the products on the right–hand side. Next we balance the equation by determining the coefficients that provide equal numbers of each type of atom on both sides of the equation. For most purposes, a balanced equation should contain the smallest possible whole-number coefficients.

In balancing an equation, you need to understand the difference between coefficients and subscripts. As \blacktriangleright Figure 3.3 illustrates, changing a subscript in a formula—from H_2O to H_2O_2 , for example—changes the identity of the substance. The substance H_2O_2 , hydrogen peroxide, is quite different from the substance H_2O , water. *Never change subscripts when balancing an equation*. In contrast, placing a coefficient in front of a formula changes only the *amount* of the substance and not its *identity*. Thus, 2 H_2O means two molecules of water, 3 H_2O means three molecules of water, and so forth.

To illustrate the process of balancing an equation, consider the reaction that occurs when methane (CH_4) , the principal component of natural gas, burns in air to produce

^{*}Lavoisier, Antoine. "Elements of Chemistry." 1790.

▲ Figure 3.3 The difference between changing subscripts and changing coefficients in chemical equations.

carbon dioxide gas (CO_2) and water vapor (H_2O) (∇ Figure 3.4). Both products contain oxygen atoms that come from O_2 in the air. Thus, O_2 is a reactant, and the unbalanced equation is

$$CH_4 + O_2 \longrightarrow CO_2 + H_2O$$
 (unbalanced) [3.2]

It is usually best to balance first those elements that occur in the fewest chemical formulas in the equation. In our example, C appears in only one reactant (CH_4) and one product (CO_2) . The same is true for H (CH_4) and (CO_2) . Notice, however, that O appears in one reactant (O_2) and two products (CO_2) and (CO_2) and (CO_2) and (CO_2) and (CO_2) and (CO_2) are molecule of (CO_2) and (CO_2) are molecule of (CO_2) and (CO_2) are molecule of (CO_2) and (CO_2) are substances *must* be the same in the balanced equation. Therefore, we start by choosing the coefficient 1 (unwritten) for both (CO_2) and (CO_2) .

Next we focus on H. On the left side of the equation we have CH_4 , which has four H atoms, whereas on the right side of the equation we have H_2O , containing two H atoms. To balance the H atoms in the equation we place the coefficient 2 in front of H_2O . Now there are four H atoms on each side of the equation:

$$CH_4 + O_2 \longrightarrow CO_2 + 2 H_2O$$
 (unbalanced) [3.3]

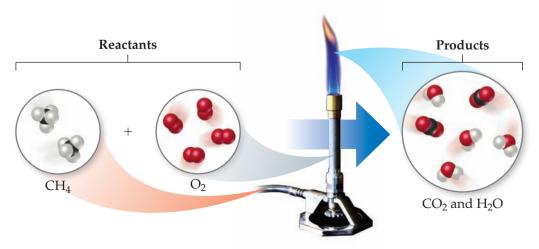

While the equation is now balanced with respect to hydrogen and carbon, it is not yet balanced for oxygen. Adding the coefficient 2 in front of O_2 balances the equation by giving four O atoms on each side (2 × 2 left, 2 + 2 × 1 right):

$$CH_4 + 2 O_2 \longrightarrow CO_2 + 2 H_2O$$
 (balanced) [3.4]

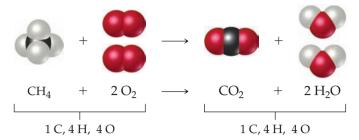

The molecular view of the balanced equation is shown in Figure 3.5.

▲ GO FIGURE

In the molecular level views shown in the figure how many C, H, and O atoms are present on the reactant side? Are the same number of each type of atom present on the product side?

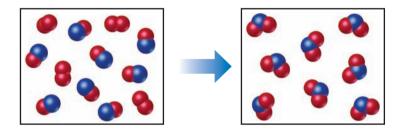

▲ Figure 3.4 Methane reacts with oxygen in a Bunsen burner.

▲ Figure 3.5 Balanced chemical equation for the combustion of CH₄.

SAMPLE EXERCISE 3.1 Interpreting and Balancing Chemical Equations

The following diagram represents a chemical reaction in which the red spheres are oxygen atoms and the blue spheres are nitrogen atoms. (a) Write the chemical formulas for the reactants and products. (b) Write a balanced equation for the reaction. (c) Is the diagram consistent with the law of conservation of mass?

SOLUTION

- (a) The left box, which represents reactants, contains two kinds of molecules, those composed of two oxygen atoms (O₂) and those composed of one nitrogen atom and one oxygen atom (NO). The right box, which represents products, contains only one kind of molecule, which is composed of one nitrogen atom and two oxygen atoms (NO₂).
- (b) The unbalanced chemical equation is

$$O_2 + NO \longrightarrow NO_2$$
 (unbalanced)

An inventory of atoms on each side of the equation shows that there are one N and three O on the left side of the arrow and one N and two O on the right. To balance O we must increase the number of O atoms on the right while keeping the coefficients for NO and NO_2 equal. Sometimes a trial-and-error approach is required; we need to go back and forth several times from one side of an equation to the other, changing coefficients first on one side of the equation and then the other until it is balanced. In our present case, let's start by increasing the number of O atoms on the right side of the equation by placing the coefficient 2 in front of NO_2 :

$$O_2 + NO \longrightarrow 2 NO_2$$
 (unbalanced)

Now the equation gives two N atoms and four O atoms on the right, so we go back to the left side. Placing the coefficient 2 in front of NO balances both N and O:

$$\underbrace{O_2 + 2 \, NO}_{2 \, N, \, 4 \, O} \longrightarrow \underbrace{2 \, NO_2}_{2 \, N, \, 4 \, O} \text{(balanced)}$$

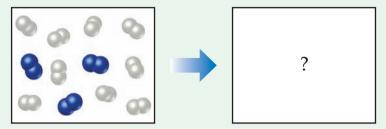

(c) The reactants box contains four O₂ and eight NO. Thus, the molecular ratio is one O₂ for each two NO, as required by the balanced equation. The products box contains eight NO₂, which means the number of NO₂ product molecules equals the number of NO reactant molecules, as the balanced equation requires.

There are eight N atoms in the eight NO molecules in the reactants box. There are also $4 \times 2 = 8$ O atoms in the O₂ molecules and 8 O atoms in the NO molecules,

giving a total of 16 O atoms. In the products box, we find eight NO_2 molecules, which contain eight N atoms and $8\times 2=16$ O atoms. Because there are equal numbers of N and O atoms in the two boxes, the drawing is consistent with the law of conservation of mass.

Practice Exercise 1

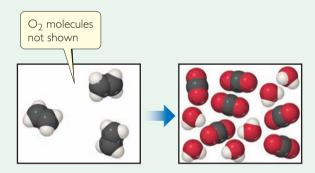

In the following diagram, the white spheres represent hydrogen atoms and the blue spheres represent nitrogen atoms.

The two reactants combine to form a single product, ammonia, NH₃, which is not shown. Write a balanced chemical equation for the reaction. Based on the equation and the contents of the left (reactants) box, find how many NH₃ molecules should be shown in the right (products) box. (a) 2, (b) 3, (c) 4, (d) 6, (e) 9.

Practice Exercise 2

In the following diagram, the white spheres represent hydrogen atoms, the black spheres carbon atoms, and the red spheres oxygen atoms.

In this reaction, there are two reactants, ethylene, C_2H_4 , which is shown, and oxygen, O_2 , which is not shown, and two products, CO_2 and H_2O , both of which are shown. (a) Write a balanced chemical equation for the reaction. (b) Determine the number of O_2 molecules that should be shown in the left (reactants) box.

Indicating the States of Reactants and Products

Symbols indicating the physical state of each reactant and product are often shown in chemical equations. We use the symbols (g), (l), (s), and (aq) for substances that are gases, liquids, solids, and dissolved in aqueous (water) solution, respectively. Thus, Equation 3.4 can be written

$$CH_4(g) + 2 O_2(g) \longrightarrow CO_2(g) + 2 H_2O(g)$$
 [3.5]

Sometimes symbols that represent the conditions under which the reaction proceeds appear above or below the reaction arrow. One example that we will encounter later in this chapter involves the symbol Δ (Greek uppercase delta); a cap delta above the reaction arrow indicates the addition of heat.

SAMPLE EXERCISE 3.2

EXERCISE 3.2 Balancing Chemical Equations

Balance the equation

SOLUTION

$$Na(s) + H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$$

Begin by counting each kind of atom on the two sides of the arrow. There are one Na, one O, and two H on the left side, and one Na, one O, and three H on the right. The Na and O atoms are balanced, but the number of H atoms is not. To increase the number of H atoms on the left, let's try placing the coefficient 2 in front of H₂O:

Although beginning this way does not balance H, it does increase the number of reactant H atoms, which we need to do. (Also, adding the coefficient 2 on $\rm H_2O$ unbalances O, but we will take care of that after we balance H.) Now that we have 2 $\rm H_2O$ on the left, we balance H by putting the coefficient 2 in front of NaOH:

Balancing H in this way brings O into balance, but now Na is unbalanced, with one Na on the left and two on the right. To rebalance Na, we put the coefficient 2 in front of the reactant:

$$Na(s) + 2 H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$$

$$Na(s) + 2 H_2O(l) \longrightarrow 2 NaOH(aq) + H_2(g)$$

$$2 \operatorname{Na}(s) + 2 \operatorname{H}_2 \operatorname{O}(l) \longrightarrow 2 \operatorname{NaOH}(aq) + \operatorname{H}_2(g)$$

We now have two Na atoms, four H atoms, and two O atoms on each side. The equation is balanced.

Comment Notice that we moved back and forth, placing a coefficient in front of H_2O , then NaOH, and finally Na. In balancing equations, we often find ourselves following this pattern of moving back and forth from one side of the arrow to the other, placing coefficients first in front of a formula on one side and then in front of a formula on the other side until the equation is balanced. You can always tell if you have balanced your equation correctly by checking that the number of atoms of each element is the same on the two sides of the arrow, and that you've chosen the smallest set of coefficients that balances the equation.

Practice Exercise 1

The unbalanced equation for the reaction between methane and bromine is

$$_CH_4(g) + _Br_2(l) \longrightarrow _CBr_4(s) + _HBr(g)$$

Once this equation is balanced what is the value of the coefficient in front of bromine Br_2 ? (a) 1, (b) 2, (c) 3, (d) 4, (e) 6.

Practice Exercise 2

Balance these equations by providing the missing coefficients:

(a) _ Fe(s) + _O₂(g)
$$\longrightarrow$$
 _Fe₂O₃(s)
(b) _ Al(s) + _ HCl(aq) \longrightarrow _ AlCl₃(aq) + _ H₂(g)
(c) _ CaCO₃(s) + _ HCl(aq) \longrightarrow _ CaCl₂(aq) + _ CO₂(g) + _ H₂O(l)

3.2 | Simple Patterns of Chemical Reactivity

In this section we examine three types of reactions that we see frequently throughout this chapter: combination reactions, decomposition reactions, and combustion reactions. Our first reason for examining these reactions is to become better acquainted with chemical reactions and their balanced equations. Our second reason is to consider how we might predict the products of some of these reactions knowing only their reactants. The key to predicting the products formed by a given combination of reactants is recognizing general patterns of chemical reactivity. Recognizing a pattern of reactivity for a class of substances gives you a broader understanding than merely memorizing a large number of unrelated reactions.

Combination and Decomposition Reactions

In **combination reactions** two or more substances react to form one product (▶ Table 3.1). For example, magnesium metal burns brilliantly in air to produce magnesium oxide (▶ Figure 3.6):

$$2 \operatorname{Mg}(s) + \operatorname{O}_2(g) \longrightarrow 2 \operatorname{MgO}(s)$$
 [3.6]

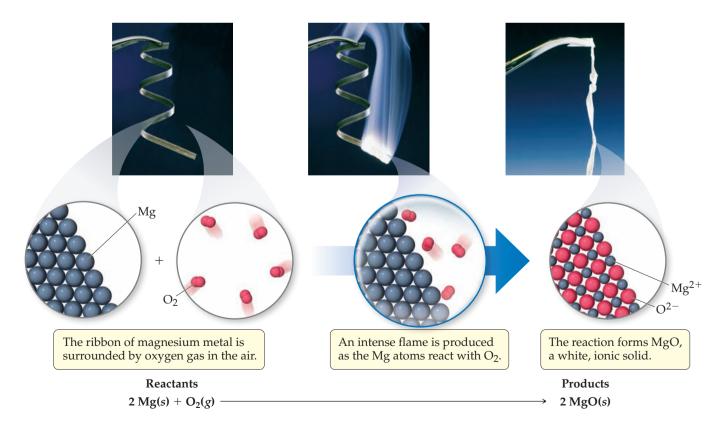

This reaction is used to produce the bright flame generated by flares and some fireworks.

A combination reaction between a metal and a nonmetal, as in Equation 3.6, produces an ionic solid. Recall that the formula of an ionic compound can be determined from the charges of its ions. ∞ (Section 2.7) When magnesium reacts with oxygen, the magnesium loses electrons and forms the magnesium ion, Mg^{2+} . The oxygen gains electrons and forms the oxide ion, O^{2-} . Thus, the reaction product is MgO.

You should be able to recognize when a reaction is a combination reaction and to predict the products when the reactants are a metal and a nonmetal.

Table 3.1 Combination and Decomposition Reactions **Combination Reactions** $A + B \longrightarrow C$ Two or more reactants combine to form a single product. Many elements react $C(s) + O_2(g) \longrightarrow CO_2(g)$ with one another in this fashion to form $N_2(g) + 3 H_2(g) \longrightarrow 2 NH_3(g)$ compounds. $CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq)$ **Decomposition Reactions** $C \longrightarrow A + B$ A single reactant breaks apart to form two or more substances. Many compounds react $2 \text{ KClO}_3(s) \longrightarrow 2 \text{ KCl}(s) + 3 \text{ O}_2(g)$ this way when heated. $PbCO_3(s) \longrightarrow PbO(s) + CO_2(g)$

 $Cu(OH)_2(s) \longrightarrow CuO(s) + H_2O(g)$

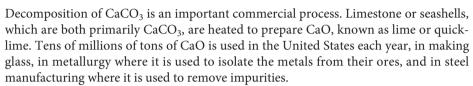

▲ Figure 3.6 Combustion of magnesium metal in air, a combination reaction.

■ Give It Some Thought

When Na and S undergo a combination reaction, what is the chemical formula of the product?

In a **decomposition reaction** one substance undergoes a reaction to produce two or more other substances (Table 3.1). For example, many metal carbonates decompose to form metal oxides and carbon dioxide when heated:

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$$
 [3.7]

The decomposition of sodium azide (NaN₃) rapidly releases N₂(g), so this reaction is used to inflate safety air bags in automobiles (\P Figure 3.7):

$$2 \operatorname{NaN}_3(s) \longrightarrow 2 \operatorname{Na}(s) + 3 \operatorname{N}_2(g)$$
 [3.8]

The system is designed so that an impact ignites a detonator cap, which in turn causes NaN_3 to decompose explosively. A small quantity of NaN_3 (about 100 g) forms a large quantity of gas (about 50 L).

▲ Figure 3.7 Decomposition of sodium azide, $NaN_3(s)$, is used to inflate air bags in automobiles.

SAMPLE EXERCISE 3.3

Writing Balanced Equations for Combination and Decomposition Reactions

Write a balanced equation for (a) the combination reaction between lithium metal and fluorine gas and (b) the decomposition reaction that occurs when solid barium carbonate is heated (two products form, a solid and a gas).

SOLUTION

(a) With the exception of mercury, all metals are solids at room temperature. Fluorine occurs as a diatomic molecule. Thus, the reactants are Li(s) and F₂(g). The product will be composed of a metal and a nonmetal, so we expect it to be an ionic solid. Lithium ions have a 1+ charge, Li⁺, whereas fluoride ions have a 1- charge, F⁻. Thus, the chemical formula for the product is LiF. The balanced chemical equation is

$$2 \operatorname{Li}(s) + \operatorname{F}_2(g) \longrightarrow 2 \operatorname{LiF}(s)$$

(b) The chemical formula for barium carbonate is BaCO₃. As mentioned, many metal carbonates decompose to metal oxides and carbon dioxide when heated. In Equation 3.7, for example, CaCO₃ decomposes to form CaO and CO₂. Thus, we expect BaCO₃ to decompose to BaO and CO₂. Barium and calcium are both in group 2A in the periodic table, which further suggests they react in the same way:

$$BaCO_3(s) \longrightarrow BaO(s) + CO_2(g)$$

Practice Exercise 1

Which of the following reactions is the balanced equation that represents the decomposition reaction that occurs when silver (I) oxide is heated? (a) $AgO(s) \longrightarrow Ag(s) + O(g)$; (b) $2 AgO(s) \longrightarrow 2 Ag(s) + O_2(g)$; (c) $Ag_2O(s) \longrightarrow 2 Ag(s) + O(g)$; (d) $2 Ag_2O(s) \longrightarrow 4 Ag(s) + O_2(g)$; (e) $Ag_2O(s) \longrightarrow 2 Ag(s) + O_2(g)$.

Practice Exercise 2

Write a balanced equation for (a) solid mercury (II) sulfide decomposing into its component elements when heated and (b) aluminum metal combining with oxygen in the air.

Combustion Reactions

Combustion reactions are rapid reactions that produce a flame. Most combustion reactions we observe involve O_2 from air as a reactant. Equation 3.5 illustrates a general class of reactions involving the burning, or combustion, of hydrocarbons (compounds that contain only carbon and hydrogen, such as CH_4 and C_2H_4). ∞ (Section 2.9)

Hydrocarbons combusted in air react with O_2 to form CO_2 and H_2O .* The number of molecules of O_2 required and the number of molecules of CO_2 and H_2O formed depend on the composition of the hydrocarbon, which acts as the fuel in the reaction. For example, the combustion of propane (C_3H_8 , \triangleright Figure 3.8), a gas used for cooking and home heating, is described by the equation

$$C_3H_8(g) + 5 O_2(g) \longrightarrow 3 CO_2(g) + 4 H_2O(g)$$
 [3.9]

The state of the water in this reaction, $H_2O(g)$ or $H_2O(l)$, depends on the reaction conditions. Water vapor, $H_2O(g)$, is formed at high temperature in an open container.

Combustion of oxygen-containing derivatives of hydrocarbons, such as CH_3OH , also produces CO_2 and H_2O . The rule that hydrocarbons and their oxygen-containing derivatives form CO_2 and H_2O when they burn in air summarizes the reactions of about 3 million compounds with oxygen. Many substances that our bodies use as energy sources, such as the sugar glucose $(C_6H_{12}O_6)$, react with O_2 to form CO_2 and H_2O . In our bodies, however, the reactions take place in a series of intermediate steps that occur at body temperature. These reactions that involve intermediate steps are described as *oxidation reactions* instead of combustion reactions.

A GO FIGURE

Does this reaction produce or consume thermal energy (heat)?

▲ Figure 3.8 Propane burning in air. Liquid propane in the tank, C_3H_8 , vaporizes and mixes with air as it escapes through the nozzle. The combustion reaction of C_3H_8 and O_2 produces a blue flame.

SAMPLE EXERCISE 3.4 Writing Balanced Equations for Combustion Reactions

Write the balanced equation for the reaction that occurs when methanol, $CH_3OH(l)$, is burned in air.

SOLUTION

When any compound containing C, H, and O is combusted, it reacts with the $O_2(g)$ in air to produce $CO_2(g)$ and $H_2O(g)$. Thus, the unbalanced equation is

$$CH_3OH(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

The C atoms are balanced, one on each side of the arrow. Because CH_3OH has four H atoms, we place the coefficient 2 in front of H_2O to balance the H atoms:

$$CH_3OH(l) + O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$$

Adding this coefficient balances H but gives four O atoms in the products. Because there are only three O atoms in the reactants, we are not finished. We can place the coefficient $\frac{3}{2}$ in front of O_2 to give four O atoms in the reactants ($\frac{3}{2} \times 2 = 3$ O atoms in $\frac{3}{2}O_2$):

$$CH_3OH(l) + \frac{3}{2}O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$$

Although this equation is balanced, it is not in its most conventional form because it contains a fractional coefficient. However,

multiplying through by 2 removes the fraction and keeps the equation balanced:

$$2 \text{ CH}_3\text{OH}(l) + 3 \text{ O}_2(g) \longrightarrow 2 \text{ CO}_2(g) + 4 \text{ H}_2\text{O}(g)$$

Practice Exercise 1

Write the balanced equation for the reaction that occurs when ethylene glycol, $C_2H_4(OH)_2$, burns in air. (a) $C_2H_4(OH)_2(l) + 5/2 O_2(g) \longrightarrow 2 CO_2(g) + 3 H_2O(g)$ (b) $2 C_2H_4(OH)_2(l) + 5 O_2(g) \longrightarrow 4 CO_2(g) + 6 H_2O(g)$ (c) $C_2H_4(OH)_2(l) + 3 O_2(g) \longrightarrow 2 CO_2(g) + 3 H_2O(g)$ (d) $C_2H_4(OH)_2(l) + 5 O(g) \longrightarrow 2 CO_2(g) + 3 H_2O(g)$ (e) $4 C_2H_4(OH)_2(l) + 10 O_2(g) \longrightarrow 8 CO_2(g) + 12 H_2O(g)$

Practice Exercise 2

Write the balanced equation for the reaction that occurs when ethanol, $C_2H_3OH(I)$, burns in air.

3.3 | Formula Weights

Chemical formulas and chemical equations both have a *quantitative* significance in that the subscripts in formulas and the coefficients in equations represent precise quantities. The formula H₂O indicates that a molecule of this substance (water) contains exactly two atoms of hydrogen and one atom of oxygen. Similarly, the coefficients in a balanced chemical equation indicate the relative quantities of reactants and products. But how do

^{*}When there is an insufficient quantity of O_2 present, carbon monoxide (CO) is produced along with CO_2 ; this is called incomplete combustion. If the quantity of O_2 is severely restricted, the fine particles of carbon we call soot are produced. Complete combustion produces only CO_2 and H_2O . Unless stated to the contrary, we will always take combustion to mean complete combustion.

we relate the numbers of atoms or molecules to the amounts we measure in the laboratory? If you wanted to react hydrogen and oxygen in exactly the right ratio to make H₂O, how would you make sure the reactants contain a 2:1 ratio of hydrogen atoms to oxygen atoms?

It is not possible to count individual atoms or molecules, but we can indirectly determine their numbers if we know their masses. So, if we are to calculate amounts of reactants needed to obtain a given amount of product, or otherwise extrapolate quantitative information from a chemical equation or formula, we need to know more about the masses of atoms and molecules.

Formula and Molecular Weights

The **formula weight** (FW) of a substance is the sum of the atomic weights (AW) of the atoms in the chemical formula of the substance. Using atomic weights, we find, for example, that the formula weight of sulfuric acid (H_2SO_4) is 98.1 amu (atomic mass units):

FW of
$$H_2SO_4 = 2(AW \text{ of } H) + (AW \text{ of } S) + 4(AW \text{ of } O)$$

= $2(1.0 \text{ amu}) + 32.1 \text{ amu} + 4(16.0 \text{ amu})$
= 98.1 amu

For convenience, we have rounded off the atomic weights to one decimal place, a practice we will follow in most calculations in this book.

If the chemical formula is the chemical symbol of an element, such as Na, the formula weight equals the atomic weight of the element, in this case 23.0 amu. If the chemical formula is that of a molecule, the formula weight is also called the **molecular weight** (MW). The molecular weight of glucose $(C_6H_{12}O_6)$, for example, is

MW of
$$C_6H_{12}O_6 = 6(12.0 \text{ amu}) + 12(1.0 \text{ amu}) + 6(16.0 \text{ amu}) = 180.0 \text{ amu}$$

Because ionic substances exist as three-dimensional arrays of ions (see Figure 2.21), it is inappropriate to speak of molecules of these substances. Instead we use the empirical formula as the formula unit, and the formula weight of an ionic substance is determined by summing the atomic weights of the atoms in the empirical formula. For example, the formula unit of $CaCl_2$ consists of one Ca^{2+} ion and two Cl^- ions. Thus, the formula weight of $CaCl_2$ is

FW of
$$CaCl_2 = 40.1 \text{ amu} + 2(35.5 \text{ amu}) = 111.1 \text{ amu}$$

SAMPLE EXERCISE 3.5 Calculating Formula Weights

Calculate the formula weight of (a) sucrose, $C_{12}H_{22}O_{11}$ (table sugar); and (b) calcium nitrate, $Ca(NO_3)_2$.

SOLUTION

(a) By adding the atomic weights of the atoms in sucrose, we find the formula weight to be 342.0 amu:

12 C atoms = 12(12.0 amu) = 144.0 amu22 H atoms = 22(1.0 amu) = 22.0 amu11 O atoms = $11(16.0 \text{ amu}) = \frac{176.0 \text{ amu}}{342.0 \text{ amu}}$

(b) If a chemical formula has parentheses, the subscript outside the parentheses is a multiplier for all atoms inside. Thus, for Ca(NO₃)₂ we have

1 Ca atom = 1(10.0 amu) = $\frac{342.0 \text{ amu}}{342.0 \text{ amu}}$ 1 Ca atom = 1(40.1 amu) = 40.1 amu 2 N atoms = 2(14.0 amu) = 28.0 amu 6 O atoms = 6(16.0 amu) = $\frac{96.0 \text{ amu}}{164.1 \text{ amu}}$

Practice Exercise 1

Which of the following is the correct formula weight for calcium phosphate? (a) 310.2 amu, (b) 135.1 amu, (c) 182.2 amu, (d) 278.2 amu, (e) 175.1 amu.

Practice Exercise 2

Calculate the formula weight of (a) Al(OH)₃, (b) CH₃OH, and (c) TaON.

Percentage Composition from Chemical Formulas

Chemists must sometimes calculate the *percentage composition* of a compound—that is, the percentage by mass contributed by each element in the substance. Forensic chemists, for example, can measure the percentage composition of an unknown powder and compare it with the percentage compositions of suspected substances (for example, sugar, salt, or cocaine) to identify the powder.

Calculating the percentage composition of any element in a substance (sometimes called the **elemental composition** of a substance) is straightforward if the chemical formula is known. The calculation depends on the formula weight of the substance, the atomic weight of the element of interest, and the number of atoms of that element in the chemical formula:

$$\text{\% composition of element} = \frac{ \left(\begin{array}{c} \text{number of atoms} \\ \text{of element} \end{array} \right) \left(\begin{array}{c} \text{atomic weight} \\ \text{of element} \end{array} \right) }{ \text{formula weight of substance}} \times 100\% \ [3.10]$$

SAMPLE EXERCISE 3.6 Calculating Percentage Composition

Calculate the percentage of carbon, hydrogen, and oxygen (by mass) in C₁₂H₂₂O₁₁.

SOLUTION

Let's examine this question using the problem-solving steps in the accompanying "Strategies in Chemistry: Problem Solving" essay.

Analyze We are given a chemical formula and asked to calculate the percentage by mass of each element

Plan We use Equation 3.10, obtaining our atomic weights from a periodic table. We know the denominator in Equation 3.10, the formula weight of $C_{12}H_{22}O_{11}$, from Sample Exercise 3.5. We must use that value in three calculations, one for each element.

Solve

$$%C = \frac{(12)(12.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 42.1\%$$

$$%H = \frac{(22)(1.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 6.4\%$$

$$%O = \frac{(11)(16.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 51.5\%$$

Check Our calculated percentages must add up to 100%, which they do. We could have used more significant figures for our atomic weights, giving more significant figures for our percentage composition, but we have adhered to our suggested guideline of rounding atomic weights to one digit beyond the decimal point.

Practice Exercise 1

What is the percentage of nitrogen, by mass, in calcium nitrate? (a) 8.54%, (b) 17.1%, (c) 13.7%, (d) 24.4%, (e) 82.9%.

Practice Exercise 2

Calculate the percentage of potassium, by mass, in K₂PtCl₆.

3.4 | Avogadro's Number and the Mole

Even the smallest samples we deal with in the laboratory contain enormous numbers of atoms, ions, or molecules. For example, a teaspoon of water (about 5 mL) contains 2×10^{23} water molecules, a number so large it almost defies comprehension. Chemists therefore have devised a counting unit for describing large numbers of atoms or molecules.

Strategies in Chemistry

Problem Solving

Practice is the key to success in solving problems. As you practice, you can improve your skills by following these steps:

- 1. **Analyze the problem.** Read the problem carefully. What does it say? Draw a picture or diagram that will help you to visualize the problem. Write down both the data you are given and the quantity you need to obtain (the unknown).
- 2. Develop a plan for solving the problem. Consider a possible path between the given information and the unknown. What principles or equations relate the known data to the unknown? Recognize that some data may not be given explicitly in the
- problem; you may be expected to know certain quantities (such as Avogadro's number) or look them up in tables (such as atomic weights). Recognize also that your plan may involve either a single step or a series of steps with intermediate answers.
- 3. **Solve the problem.** Use the known information and suitable equations or relationships to solve for the unknown. Dimensional analysis (Section 1.6) is a useful tool for solving a great number of problems. Be careful with significant figures, signs, and units.
- 4. Check the solution. Read the problem again to make sure you have found all the solutions asked for in the problem. Does your answer make sense? That is, is the answer outrageously large or small or is it in the ballpark? Finally, are the units and significant figures correct?

In everyday life we use such familiar counting units as dozen (12 objects) and gross (144 objects). In chemistry the counting unit for numbers of atoms, ions, or molecules in a laboratory-size sample is the *mole*, abbreviated mol. One **mole** is the amount of matter that contains as many objects (atoms, molecules, or whatever other objects we are considering) as the number of atoms in exactly 12 g of isotopically pure 12 C. From experiments, scientists have determined this number to be $6.02214129 \times 10^{23}$, which we usually round to 6.02×10^{23} . Scientists call this value **Avogadro's number**, N_A , in honor of the Italian scientist Amedeo Avogadro (1776–1856), and it is often cited with units of reciprocal moles, 6.02×10^{23} mol $^{-1}$.* The unit (read as either "inverse mole" or "per mole") reminds us that there are 6.02×10^{23} objects per one mole. A mole of atoms, a mole of molecules, or a mole of anything else all contain Avogadro's number of objects:

1 mol ^{12}C atoms = 6.02×10^{23} ^{12}C atoms 1 mol H_2O molecules = 6.02×10^{23} H_2O molecules 1 mol NO_3^- ions = 6.02×10^{23} NO_3^- ions

Avogadro's number is so large that it is difficult to imagine. Spreading 6.02×10^{23} marbles over Earth's surface would produce a layer about 3 miles thick. Avogadro's number of pennies placed side by side in a straight line would encircle Earth 300 trillion (3×10^{14}) times.

SAMPLE EVERCISE 3

EXERCISE 3.7 Estimating Numbers of Atoms

Without using a calculator, arrange these samples in order of increasing numbers of carbon atoms: $12 \, \mathrm{g}^{12} \mathrm{C}$, $1 \, \mathrm{mol} \, \mathrm{C}_2 \mathrm{H}_2$, $9 \, \times \, 10^{23} \, \mathrm{molecules}$ of CO_2 .

SOLUTION

Analyze We are given amounts of three substances expressed in grams, moles, and number of molecules and asked to arrange the samples in order of increasing numbers of C atoms.

Plan To determine the number of C atoms in each sample, we must convert 12 g 12 C, 1 mol C_2 H₂, and 9 × 10^{23} molecules CO₂ to numbers of C atoms. To make these conversions, we use the definition of mole and Avogadro's number.

Solve One mole is defined as the amount of matter that contains as many units of the matter as there are C atoms in exactly 12 g of ^{12}C . Thus, 12 g of ^{12}C contains 1 mol of C atoms $=6.02\times10^{23}$ C atoms. One mol of C_2H_2 contains 6.02×10^{23} C_2H_2 molecules. Because there are two C atoms in each molecule, this sample contains 12.04×10^{23} C atoms. Because each CO_2 molecule contains one C atom, the CO_2 sample contains 9×10^{23} C atoms. Hence, the order is 12 g ^{12}C (6 \times 10^{23} C atoms) $<9\times10^{23}$ CO $_2$ molecules $(9\times10^{23}$ C atoms) <1 mol C_2H_2 (12 \times 10^{23} C atoms).

Check We can check our results by comparing numbers of moles of C atoms in the samples because the number of moles is proportional to the number of atoms. Thus, 12 g of 12 C is 1 mol C, 1 mol of C_2H_2 contains 2 mol C, and 9 \times 10 23 molecules of CO₂ contain 1.5 mol C, giving the same order as stated previously.

Practice Exercise 1

Determine which of the following samples contains the fewest sodium atoms? (a) 1 mol sodium oxide, (b) 45 g sodium fluoride, (c) 50 g sodium chloride, (d) 1 mol sodium nitrate?

Practice Exercise 2

Without using a calculator, arrange these samples in order of increasing numbers of O atoms: 1 mol H_2O , 1 mol CO_2 , 3×10^{23} molecules of O_3 .

^{*}Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the National Institute of Standards and Technology (NIST), but Avogadro's number remains in widespread usage and is used in most places in this book.

SAMPLE EXERCISE 3.8 Converting Moles to Number of Atoms

Calculate the number of H atoms in 0.350 mol of C₆H₁₂O₆.

SOLUTION

Analyze We are given the amount of a substance (0.350 mol) and its chemical formula $C_6H_{12}O_6$. The unknown is the number of H atoms in the sample.

Plan Avogadro's number provides the conversion factor between number of moles of $C_6H_{12}O_6$ and number of molecules of $C_6H_{12}O_6$: 1 mol $C_6H_{12}O_6 = 6.02 \times 10^{23}$ molecules of $C_6H_{12}O_6$. Once we know the number of molecules of $C_6H_{12}O_6$, we can use the chemical formula, which tells us that each molecule of $C_6H_{12}O_6$ contains 12 H atoms. Thus, we convert moles of $C_6H_{12}O_6$ to molecules of $C_6H_{12}O_6$ and then determine the number of atoms of H from the number of molecules of $C_6H_{12}O_6$:

Moles
$$C_6H_{12}O_6 \longrightarrow \text{molecules } C_6H_{12}O_6 \longrightarrow \text{atoms } H$$

Solve

$$\begin{split} \text{H atoms} &= (0.350 \text{ mol } C_6 \text{H}_{12} \text{O}_6) \bigg(\frac{6.02 \times 10^{23} \text{ molecules } C_6 \text{H}_{12} \text{O}_6}{1 \text{ mol } C_6 \text{H}_{12} \text{O}_6} \bigg) \bigg(\frac{12 \text{ H atoms}}{1 \text{ molecule } C_6 \text{H}_{12} \text{O}_6} \bigg) \\ &= 2.53 \times 10^{24} \text{ H atoms} \end{split}$$

Check We can do a ballpark calculation, figuring that $0.35(6\times10^{23})$ is about 2×10^{23} molecules of $C_6H_{12}O_6$. We know that each one of these molecules contains 12 H atoms. $12(2\times10^{23})$ gives $24\times10^{23}=2.4\times10^{24}$ H atoms, which is close to our result. Because we were asked for the number of H atoms, the units of our answer are correct. We check, too, for significant figures. The given data had three significant figures, as does our answer.

Practice Exercise 1

How many sulfur atoms are in (a) 0.45 mol BaSO₄ and (b) 1.10 mol of aluminum sulfide?

Practice Exercise 2

How many oxygen atoms are in (a) 0.25 mol $Ca(NO_3)_2$ and (b) 1.50 mol of sodium carbonate?

Molar Mass

A dozen is the same number, 12, whether we have a dozen eggs or a dozen elephants. Clearly, however, a dozen eggs does not have the same mass as a dozen elephants. Similarly, a mole is always the *same number* (6.02×10^{23}) , but 1-mol samples of different substances have *different masses*. Compare, for example, 1 mol of 12 C and 1 mol of 24 Mg. A single 12 C atom has a mass of 12 amu, whereas a single 24 Mg atom is twice as massive, 24 amu (to two significant figures). Because a mole of anything always contains the same number of particles, a mole of 24 Mg must be twice as massive as a mole of 12 C. Because a mole of 12 C has a mass of 12 g (by definition), a mole of 24 Mg must have a mass of 24 g. This example illustrates a general rule relating the mass of an atom to the mass of Avogadro's number (1 mol) of these atoms: *The atomic weight of an element in atomic mass units is numerically equal to the mass in grams of 1 mol of that element.* For example (the symbol \Rightarrow means therefore)

Cl has an atomic weight of 35.5 amu \Rightarrow 1 mol Cl has a mass of 35.5 g.

Au has an atomic weight of 197 amu \Rightarrow 1 mol Au has a mass of 197 g.

For other kinds of substances, the same numerical relationship exists between formula weight and mass of 1 mol of a substance:

 H_2O has a formula weight of 18.0 amu \Rightarrow 1 mol H_2O has a mass of 18.0 g (\blacktriangleright Figure 3.9).

NaCl has a formula weight of 58.5 amu \Rightarrow 1 mol NaCl has a mass of 58.5 g.

GO FIGURE

How many H_2O molecules are in a 9.00-g sample of water?

Single molecule

1 molecule H₂O (18.0 amu)

Avogadro's number of water molecules in a mole of water.

1 mol H₂O (18.0 g)

▲ Figure 3.9 Comparing the mass of 1 molecule and 1 mol of H_20 . Both masses have the same number but different units (atomic mass units and grams). Expressing both masses in grams indicates their huge difference: 1 molecule of H_2O has a mass of 2.99×10^{-23} g, whereas 1 mol H_2O has a mass of 18.0 g.

Give It Some Thought

- (a) Which has more mass, a mole of water (H_2O) or a mole of glucose $(C_6H_{12}O_6)$?
- (b) Which contains more molecules, a mole of water or a mole of glucose?

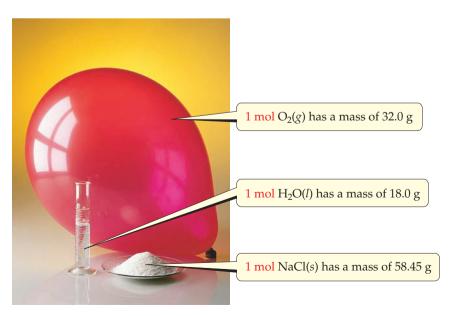

The mass in grams of one mole, often abbreviated as 1 mol, of a substance (that is, the mass in grams per mole) is called the **molar mass** of the substance. *The molar mass in grams per mole of any substance is numerically equal to its formula weight in atomic mass units*. For NaCl, for example, the formula weight is 58.5 amu and the molar mass is 58.5 g/mol. Mole relationships for several other substances are shown in ▼ Table 3.2, and ▼ Figure 3.10 shows 1 mol quantities of three common substances.

The entries in Table 3.2 for N and N_2 point out the importance of stating the chemical form of a substance when using the mole concept. Suppose you read that 1 mol of nitrogen is produced in a particular reaction. You might interpret this statement to mean 1 mol of nitrogen atoms (14.0 g). Unless otherwise stated, however, what is probably meant is 1 mol of nitrogen molecules, N_2 (28.0 g), because N_2 is the most

Table 3.2	1/616	Dolotion	china
Table 3.2	Mole	Relation	ISIIIDS

Name of Substance	Formula	Formula Weight (amu)	Molar Mass (g/mol)	Number and Kind of Particles in One Mole
Atomic nitrogen	N	14.0	14.0	$6.02 \times 10^{23} \text{N}$ atoms
Molecular nitrogen	N_2	28.0	28.0	$\begin{cases} 6.02 \times 10^{23} \text{N}_2 \text{ molecules} \\ 2(6.02 \times 10^{23}) \text{N atoms} \end{cases}$
Silver	Ag	107.9	107.9	$6.02 \times 10^{23} \text{Ag atoms}$
Silver ions	Ag^+	107.9 ^a	107.9	$6.02 \times 10^{23}\mathrm{Ag^+}$ ions
Barium chloride	BaCl_2	208.2	208.2	$\begin{cases} 6.02 \times 10^{23} \ BaCl_2 \ formula \ units \\ 6.02 \times 10^{23} \ Ba^{2+} \ ions \\ 2(6.02 \times 10^{23}) \ Cl^- \ ions \end{cases}$

^aRecall that the mass of an electron is more than 1800 times smaller than the masses of the proton and the neutron; thus, ions and atoms have essentially the same mass.

▲ Figure 3.10 One mole each of a solid (NaCl), a liquid (H_20), and a gas (0_2). In each case, the mass in grams of 1 mol—that is, the molar mass—is numerically equal to the formula weight in atomic mass units. Each of these samples contains 6.02×10^{23} formula units.

common chemical form of the element. To avoid ambiguity, it is important to state explicitly the chemical form being discussed. Using the chemical formula—N or N_2 , for instance—avoids ambiguity.

SAMPLE

EXERCISE 3.9 Calculating Molar Mass

What is the molar mass of glucose, C₆H₁₂O₆?

SOLUTION

Analyze We are given a chemical formula and asked to determine its molar mass.

Plan Because the molar mass of any substance is numerically equal to its formula weight, we first determine the formula weight of glucose by adding the atomic weights of its component atoms. The formula weight will have units of amu, whereas the molar mass has units of grams per mole (g/mol).

Solve Our first step is to determine the formula weight of glucose:

```
6 \text{ C atoms} = 6(12.0 \text{ amu}) = 72.0 \text{ amu}
12 \text{ H atoms} = 12(1.0 \text{ amu}) = 12.0 \text{ amu}
 6 \text{ O atoms} = 6(16.0 \text{ amu}) = 96.0 \text{ amu}
                                            180.0 amu
```

Because glucose has a formula weight of 180.0 amu, 1 mol of this substance (6.02 imes 10²³ molecules) has a mass of 180.0 g. In other words, $C_6H_{12}O_6$ has a molar mass of 180.0 g/mol.

Check A molar mass below 250 seems reasonable based on the earlier examples we have encountered, and grams per mole is the appropriate unit for the molar mass.

Practice Exercise 1

A sample of an ionic compound containing iron and chlorine is analyzed and found to have a molar mass of 126.8 g/mol. What is the charge of the iron in this compound? (a) 1+, (b) 2+, (c) 3+, (d) 4+.

Practice Exercise 2

Calculate the molar mass of $Ca(NO_3)_2$.

Chemistry and Life

Glucose Monitoring

Our body converts most of the food we eat into glucose. After digestion, glucose is delivered to cells via the blood. Cells need glucose to live, and the hormone insulin must be present in order for glucose to enter the cells. Normally, the body adjusts the concentration of insulin automatically, in concert with the glucose concentration after eating. However, in a diabetic person, either little or no insulin is produced (Type 1 diabetes) or insulin is produced but the cells cannot take it up properly (Type 2 diabetes). In either case the blood glucose levels are higher than they are in a normal person, typically 70-120 mg/dL. A person who has not eaten for 8 hours or more is diagnosed as diabetic if his or her glucose level is 126 mg/dL or higher.

Glucose meters work by the introduction of blood from a person, usually by a prick of the finger, onto a small strip of paper that contains chemicals that react with glucose. Insertion of the strip into a small battery-operated reader gives the glucose concentration (▼ Figure 3.11). The mechanism of the readout varies from one monitor to another—it may be a measurement of a small electrical current or measurement of light produced in a chemical reaction. Depending on the reading on any given day, a diabetic person may need to receive an injection of insulin or simply limit his or her intake of sugar-rich foods for a while.

▲ Figure 3.11 Glucose meter.

Interconverting Masses and Moles

Conversions of mass to moles and of moles to mass are frequently encountered in calculations using the mole concept. These calculations are simplified using dimensional analysis (Section 1.6), as shown in Sample Exercises 3.10 and 3.11.

SAMPLE EXERCISE 3.10 Converting Grams to Moles

Calculate the number of moles of glucose $(C_6H_{12}O_6)$ in 5.380 g of $C_6H_{12}O_6$.

SOLUTION

Analyze We are given the number of grams of a substance and its chemical formula and asked to calculate the number of moles.

Plan The molar mass of a substance provides the factor for converting grams to moles. The molar mass of $C_6H_{12}O_6$ is 180.0 g/mol (Sample Exercise 3.9).

Solve Using 1 mol $C_6H_{12}O_6 = 180.0$ g $C_6H_{12}O_6$ to write the appropriate conversion factor, we have

$$\text{Moles } C_6 H_{12} O_6 = \\ (5.380 \text{ g.} C_6 H_{12} O_6) \left(\frac{1 \text{ mol } C_6 H_{12} O_6}{180.0 \text{ g.} C_6 H_{12} O_6} \right) = \\ 0.02989 \text{ mol } C_6 H_{12} O_6$$

Check Because 5.380 g is less than the molar mass, an answer less than 1 mol is reasonable. The unit mol is appropriate. The original data had four significant figures, so our answer has four significant figures.

Practice Exercise 1

How many moles of sodium bicarbonate (NaHCO₃) are in 508 g of NaHCO₃?

Practice Exercise 2

How many moles of water are in 1.00 L of water, whose density is 1.00 g/mL?

SAMPLE EXERCISE 3.11 Converting Moles to Grams

Calculate the mass, in grams, of 0.433 mol of calcium nitrate.

SOLUTION

Analyze We are given the number of moles and the name of a substance and asked to calculate the number of grams in the substance.

Plan To convert moles to grams, we need the molar mass, which we can calculate using the chemical formula and atomic weights.

Solve Because the calcium ion is Ca^{2+} and the nitrate ion is NO_3^- , the chemical formula for calcium nitrate is $Ca(NO_3)_2$. Adding the atomic weights of the elements in the compound gives a formula weight of 164.1 amu. Using 1 mol $Ca(NO_3)_2 = 164.1$ g $Ca(NO_3)_2$ to write the appropriate conversion factor, we have

$$Grams \ Ca(NO_3)_2 = (0.433 \ mol \ Ca(NO_3)_2) \left(\frac{164.1 \ g \ Ca(NO_3)_2}{1 \ mol \ Ca(NO_3)_2}\right) = 71.1 \ g \ Ca(NO_3)_2$$

Check The number of moles is less than 1, so the number of grams must be less than the molar mass, 164.1 g. Using rounded numbers to estimate, we have $0.5 \times 150 = 75$ g, which means the magnitude of our answer is reasonable. Both the units (g) and the number of significant figures (3) are correct.

Practice Exercise 1

What is the mass, in grams, of (a) 6.33 mol of NaHCO₃ and (b) 3.0×10^{-5} mol of sulfuric acid?

Practice Exercise 2

What is the mass, in grams, of (a) 0.50 mol of diamond (C) and (b) 0.155 mol of ammonium chloride?

Interconverting Masses and Numbers of Particles

The mole concept provides the bridge between mass and number of particles. To illustrate how this bridge works, let's calculate the number of copper atoms in an old copper penny. Such a penny has a mass of about 3 g, and for this illustration we will assume it is 100% copper:

GO FIGURE

What number would you use to convert (a) moles of CH₄ to grams of CH₄ and (b) number of molecules of CH₄ to moles of CH₄?

▲ Figure 3.12 Procedure for interconverting mass and number of formula units. The number of moles of the substance is central to the calculation. Thus, the mole concept can be thought of as the bridge between the mass of a sample in grams and the number of formula units contained in the sample.

Cu atoms =
$$(3 \text{ geu}) \left(\frac{1 \text{ mol·Cu}}{63.5 \text{ geu}} \right) \left(\frac{6.02 \times 10^{23} \text{ Cu atoms}}{1 \text{ mol·Cu}} \right)$$

= $3 \times 10^{22} \text{ Cu atoms}$

We have rounded our answer to one significant figure because we used only one significant figure for the mass of the penny. Notice how dimensional analysis provides a straightforward route from grams to numbers of atoms. The molar mass and Avogadro's number are used as conversion factors to convert grams to moles and then moles to atoms. Notice also that our answer is a very large number. Any time you calculate the number of atoms, molecules, or ions in an ordinary sample of matter, you can expect the answer to be very large. In contrast, the number of moles in a sample will usually be small, often less than 1.

The general procedure for interconverting mass and number of formula units (atoms, molecules, ions, or whatever else is represented by the chemical formula) is summarized in ▲ Figure 3.12.

SAMPLE EXERCISE 3.12

Calculating Numbers of Molecules and Atoms from Mass

- (a) How many glucose molecules are in 5.23 g of C₆H₁₂O₆?
- (b) How many oxygen atoms are in this sample?

SOLUTION

Analyze We are given the number of grams and the chemical formula of a substance and asked to calculate (a) the number of molecules and (b) the number of O atoms in the substance.

Plan (a) The strategy for determining the number of molecules in a given quantity of a substance is summarized in Figure 3.12. We must convert 5.23 g to moles of C₆H₁₂O₆ and then convert moles to molecules of $C_6H_{12}O_6$. The first conversion uses the molar mass of $C_6H_{12}O_6$, 180.0 g, and the second conversion uses Avogadro's number.

Solve Molecules C₆H₁₂O₆

$$= (5.23 \text{ g } C_6 H_{12} O_6) \left(\frac{1 \text{ mol } C_6 H_{12} O_6}{180.0 \text{ g } C_6 H_{12} O_6} \right) \left(\frac{6.02 \times 10^{23} \text{ molecules } C_6 H_{12} O_6}{1 \text{ mol } C_6 H_{12} O_6} \right)$$

$$= 1.75 \times 10^{22} \text{ molecules } C_6 H_{12} O_6$$

Check Because the mass we began with is less than a mole, there should be fewer than 6.02×10^{23} molecules in the sample, which means the magnitude of our answer is reasonable. A ballpark estimate of the answer comes reasonably close to the answer we derived in this exercise: $5/200 = 2.5 \times 10^{-2}$ mol; $(2.5 \times 10^{-2})(6 \times 10^{23}) = 15 \times 10^{21} = 1.5 \times 10^{22}$ molecules. The units (molecules) and the number of significant figures (three) are appropriate.

Plan (b) To determine the number of O atoms, we use the fact that there are six O atoms in each $C_6H_{12}O_6$ molecule. Thus, multiplying the number of molecules we calculated in (a) by the factor (6 atoms O/1 molecule $C_6H_{12}O_6$) gives the number of O atoms.

Solve

Atoms O =
$$(1.75 \times 10^{22} \text{ molecules } C_6 H_{12} O_6) \left(\frac{6 \text{ atoms O}}{\text{molecule } C_6 H_{12} O_6}\right)$$

= $1.05 \times 10^{23} \text{ atoms O}$

Check The answer is six times as large as the answer to part (a), exactly what it should be. The number of significant figures (three) and the units (atoms O) are correct.

Practice Exercise 1

How many chlorine atoms are in 12.2 g of CCl₄? (a) 4.77×10^{22} , (b) 7.34×10^{24} , (c) 1.91×10^{23} , (d) 2.07×10^{23} .

Practice Exercise 2

- (a) How many nitric acid molecules are in 4.20 g of HNO₃?
- (b) How many O atoms are in this sample?

3.5 | Empirical Formulas from Analyses

As we learned in Section 2.6, the empirical formula for a substance tells us the relative number of atoms of each element in the substance. The empirical formula H_2O shows that water contains two H atoms for each O atom. This ratio also applies on the molar level: 1 mol of H_2O contains 2 mol of H atoms and 1 mol of O atoms. Conversely, the ratio of the numbers of moles of all elements in a compound gives the subscripts in the compound's empirical formula. Thus, the mole concept provides a way of calculating empirical formulas.

Mercury and chlorine, for example, combine to form a compound that is measured to be 74.0% mercury and 26.0% chlorine by mass. Thus, if we had a 100.0-g sample of the compound, it would contain 74.0 g of mercury and 26.0 g of chlorine. (Samples of any size can be used in problems of this type, but we will generally use 100.0 g to simplify the calculation of mass from percentage.) Using atomic weights to get molar masses, we can calculate the number of moles of each element in the sample:

$$(74.0 \text{ g-Hg}) \left(\frac{1 \text{ mol Hg}}{200.6 \text{ g-Hg}} \right) = 0.369 \text{ mol Hg}$$

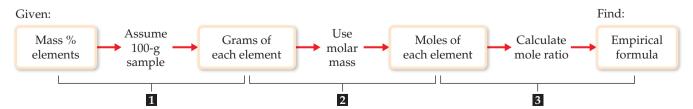

$$(26.0 \text{ g-CI}) \left(\frac{1 \text{ mol Cl}}{35.5 \text{ g-CI}} \right) = 0.732 \text{ mol Cl}$$

We then divide the larger number of moles by the smaller number to obtain the Cl:Hg mole ratio:

$$\frac{\text{moles of Cl}}{\text{moles of Hg}} = \frac{0.732 \text{ mol Cl}}{0.369 \text{ mol Hg}} = \frac{1.98 \text{ mol Cl}}{1 \text{ mol Hg}}$$

Because of experimental errors, calculated values for a mole ratio may not be whole numbers, as in the calculation here. The number 1.98 is very close to 2, however, and so we can confidently conclude that the empirical formula for the compound is $HgCl_2$. The empirical formula is correct because its subscripts are the smallest integers that express the *ratio* of atoms present in the compound. ∞ (Section 2.6)

The general procedure for determining empirical formulas is outlined in ▼ Figure 3.13.

▲ Figure 3.13 Procedure for calculating an empirical formula from percentage composition.

Give It Some Thought

Could the empirical formula determined from chemical analysis be used to tell the difference between acetylene, C_2H_2 , and benzene, C_6H_6 ?

SAMPLE EXERCISE 3.13 Calculating an Empirical Formula

Ascorbic acid (vitamin C) contains 40.92% C, 4.58% H, and 54.50% O by mass. What is the empirical formula of ascorbic acid?

SOLUTION

Analyze We are to determine the empirical formula of a compound from the mass percentages of its elements.

Plan The strategy for determining the empirical formula involves the three steps given in Figure 3.13.

Solve

 For simplicity we assume we have exactly 100 g of material, although any other mass could also be used.

In 100.00 g of ascorbic acid we have 40.92 g C, 4.58 g H, and 54.50 g O.

(2) Next we calculate the number of moles of each element. We use atomic masses with four significant figures to match the precision of our experimental masses.

Mass % elements

Assume 100-g sample

Grams of each element

Moles
$$C = (40.92 \text{ g/C}) \left(\frac{1 \text{ mol C}}{12.01 \text{ g/C}} \right) = 3.407 \text{ mol C}$$

Moles $C = (40.92 \text{ g/C}) \left(\frac{1 \text{ mol C}}{12.008 \text{ g/H}} \right) = 4.54 \text{ mol H}$

Moles $C = (40.92 \text{ g/C}) \left(\frac{1 \text{ mol C}}{1.008 \text{ g/H}} \right) = 4.54 \text{ mol H}$

Moles $C = (40.92 \text{ g/C}) \left(\frac{1 \text{ mol C}}{1.008 \text{ g/H}} \right) = 3.406 \text{ mol O}$

(3) We determine the simplest whole-number ratio of moles by dividing each number of moles by the smallest number of moles.

C:
$$\frac{3.407}{3.406}$$
 = 1.000 H: $\frac{4.54}{3.406}$ = 1.33 O: $\frac{3.406}{3.406}$ = 1.000

The ratio for H is too far from 1 to attribute the difference to experimental error; in fact, it is quite close to $1\frac{1}{3}$. This suggests we should multiply the ratios by 3 to obtain whole numbers:

$$C: H: O = (3 \times 1: 3 \times 1.33: 3 \times 1) = (3:4:3)$$

Thus, the empirical formula is C₃H₄O₃.

Check It is reassuring that the subscripts are moderate-size whole numbers. Also, calculating the percentage composition of $C_3H_4O_3$ gives values very close to the original percentages.

Practice Exercise 1

A 2.144-g sample of phosgene, a compound used as a chemical warfare agent during World War I, contains 0.260 g of carbon, 0.347 g of oxygen, and 1.537 g of chlorine. What is the empirical formula of this substance? (a) CO_2Cl_6 , (b) $COCl_2$, (c) $C_{0.022}O_{0.022}Cl_{0.044}$, (d) C_2OCl_2

Practice Exercise 2

A 5.325-g sample of methyl benzoate, a compound used in the manufacture of perfumes, contains 3.758 g of carbon, 0.316 g of hydrogen, and 1.251 g of oxygen. What is the empirical formula of this substance?

Molecular Formulas from Empirical Formulas

We can obtain the molecular formula for any compound from its empirical formula if we know either the molecular weight or the molar mass of the compound. The subscripts in the molecular formula of a substance are always whole-number multiples of the subscripts in its empirical formula. (Section 2.6) This multiple can be found by dividing the molecular weight by the empirical formula weight:

Whole-number multiple =
$$\frac{\text{molecular weight}}{\text{empirical formula weight}}$$
 [3.11]

In Sample Exercise 3.13, for example, the empirical formula of ascorbic acid was determined to be $C_3H_4O_3$. This means the empirical formula weight is 3(12.0~amu) + 4(1.0~amu) + 3(16.0~amu) = 88.0~amu. The experimentally determined molecular weight is 176 amu. Thus, we find the whole-number multiple that converts the empirical formula to the molecular formula by dividing

Whole-number multiple =
$$\frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{176 \text{ amu}}{88.0 \text{ amu}} = 2$$

Consequently, we multiply the subscripts in the empirical formula by this multiple, giving the molecular formula: $C_6H_8O_6$.

SAMPLE EXERCISE 3.14 Determining a Molecular Formula

Mesitylene, a hydrocarbon found in crude oil, has an empirical formula of C_3H_4 and an experimentally determined molecular weight of 121 amu. What is its molecular formula?

SOLUTION

Analyze We are given an empirical formula and a molecular weight of a compound and asked to determine its molecular formula.

Plan The subscripts in a compound's molecular formula are whole-number multiples of the subscripts in its empirical formula. We find the appropriate multiple by using Equation 3.11.

Solve The formula weight of the empirical formula C_3H_4 is

$$3(12.0 \text{ amu}) + 4(1.0 \text{ amu}) = 40.0 \text{ amu}$$

Next, we use this value in Equation 3.11:

Whole-number multiple =
$$\frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{121}{40.0} = 3.03$$

Only whole-number ratios make physical sense because molecules contain whole atoms. The 3.03 in this case could result from a small experimental error in the molecular weight. We therefore multiply each subscript in the empirical formula by 3 to give the molecular formula: C_9H_{12} .

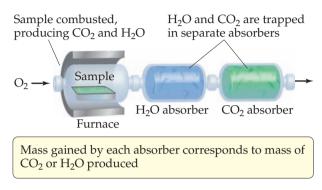

Check We can have confidence in the result because dividing molecular weight by empirical formula weight yields nearly a whole number.

Practice Exercise 1

Cyclohexane, a commonly used organic solvent, is 85.6% C and 14.4% H by mass with a molar mass of 84.2 g/mol. What is its molecular formula? (a) C_6H_1 , (b) CH_2 , (c) C_5H_{24} , (d) C_6H_{12} , (e) C_4H_8 .

Practice Exercise 2

Ethylene glycol, used in automobile antifreeze, is 38.7% C, 9.7% H, and 51.6% O by mass. Its molar mass is 62.1 g/mol. (a) What is the empirical formula of ethylene glycol? (b) What is its molecular formula?

▲ Figure 3.14 Apparatus for combustion analysis.

Combustion Analysis

One technique for determining empirical formulas in the laboratory is *combustion analysis*, commonly used for compounds containing principally carbon and hydrogen.

When a compound containing carbon and hydrogen is completely combusted in an apparatus such as that shown in \blacktriangle Figure 3.14, the carbon is converted to CO_2 and the hydrogen is converted to H_2O . \Longrightarrow (Section 3.2) The amounts of CO_2 and H_2O produced are determined by measuring the mass increase in the CO_2 and H_2O absorbers. From the masses of CO_2 and H_2O we can calculate the number of moles of C and C in the original sample and thereby the empirical formula. If a third element is present in the compound, its mass can be determined by subtracting the measured masses of C and C and C are from the original sample mass.

SAMPLE EXERCISE 3.15 Determining an Empirical Formula by Combustion Analysis

Isopropyl alcohol, sold as rubbing alcohol, is composed of C, H, and O. Combustion of 0.255 g of isopropyl alcohol produces 0.561 g of $\rm CO_2$ and 0.306 g of $\rm H_2O$. Determine the empirical formula of isopropyl alcohol.

SOLUTION

Analyze We are told that isopropyl alcohol contains C, H, and O atoms and are given the quantities of CO_2 and H_2O produced when a given quantity of the alcohol is combusted. We must determine the empirical formula for isopropyl alcohol, a task that requires us to calculate the number of moles of C, H, and O in the sample.

Plan We can use the mole concept to calculate grams of C in the CO_2 and grams of H in the H_2O —the masses of C and H in the alcohol before combustion. The mass of O in the compound equals the mass of the original sample minus the sum of the C and H masses. Once we have the C, H, and O masses, we can proceed as in Sample Exercise 3.13.

Solve Because all of the carbon in the sample is converted to CO₂, we can use dimensional analysis and the following steps to calculate the mass C in the sample.

Using the values given in this example, the mass of C is

$$\begin{aligned} \text{Grams C} &= (0.561 \text{ g-CO}_2) \bigg(\frac{1 \text{ mol-CO}_2}{44.0 \text{ g-CO}_2} \bigg) \bigg(\frac{1 \text{ mol-C}}{1 \text{ mol-CO}_2} \bigg) \bigg(\frac{12.0 \text{ g C}}{1 \text{ mol-CO}_2} \bigg) \bigg(\frac{12.0 \text{ g C}}{1 \text{ mol-CO}_2} \bigg) \end{aligned}$$

Because all of the hydrogen in the sample is converted to H_2O , we can use dimensional analysis and the following steps to calculate the mass H in the sample. We use three significant figures for the atomic mass of H to match the significant figures in the mass of H_2O produced.

Using the values given in this example, the mass of H is

Grams H =
$$(0.306 \text{ g H}_2\text{O}) \left(\frac{1 \text{ mol H}_2\text{O}}{18.0 \text{ g H}_2\text{O}}\right) \left(\frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}}\right) \left(\frac{1.01 \text{ g H}}{1 \text{ mol H}}\right)$$

= 0.0343 g H

The mass of the sample, 0.255 g, is the sum of the masses of C, H, and O. Thus, the O mass is

Mass of O = mass of sample - (mass of C + mass of H)
=
$$0.255 g - (0.153 g + 0.0343 g) = 0.068 g O$$

The number of moles of C, H, and O in the sample is therefore

Moles C =
$$(0.153 \text{ g} \circ) \left(\frac{1 \text{ mol C}}{12.0 \text{ g} \circ}\right) = 0.0128 \text{ mol C}$$

Moles H = $(0.0343 \text{ g} \cdot \text{H}) \left(\frac{1 \text{ mol H}}{1.01 \text{ g} \cdot \text{H}}\right) = 0.0340 \text{ mol H}$
Moles O = $(0.068 \text{ g} \cdot \text{O}) \left(\frac{1 \text{ mol O}}{16.0 \text{ g} \cdot \text{O}}\right) = 0.0043 \text{ mol O}$

To find the empirical formula, we must compare the relative number of moles of each element in the sample, as illustrated in Sample Exercise 3.13.

$$C: \frac{0.0128}{0.0043} = 3.0 \text{ H}: \frac{0.0340}{0.0043} = 7.9 \text{ O}: \frac{0.0043}{0.0043} = 1.0$$

The first two numbers are very close to the whole numbers 3 and 8, giving the empirical formula C_3H_8O .

Practice Exercise 1

The compound dioxane, which is used as a solvent in various industrial processes, is composed of C, H, and O atoms. Combustion of a 2.203-g sample of this compound produces 4.401 g CO₂ and 1.802 g H₂O. A separate experiment shows that it has a molar mass of 88.1 g/mol. Which of the following is the correct molecular formula for dioxane? (a) C_2H_4O , (b) $C_4H_4O_2$, (c) CH_2 , (d) $C_4H_8O_2$.

Practice Exercise 2

(a) Caproic acid, responsible for the odor of dirty socks, is composed of C, H, and O atoms. Combustion of a 0.225-g sample of this compound produces 0.512 g CO_2 and 0.209 g H_2O . What is the empirical formula of caproic acid? (b) Caproic acid has a molar mass of 116 g/mol. What is its molecular formula?

Give It Some Thought

In Sample Exercise 3.15, how do you explain that the values in our calculated C:H:O ratio are 3.0:7.9:1.0 rather than exact integers 3:8:1?

3.6 | Quantitative Information from Balanced Equations

The coefficients in a chemical equation represent the relative numbers of molecules in a reaction. The mole concept allows us to convert this information to the masses of the substances in the reaction. For instance, the coefficients in the balanced equation

$$2 H2(g) + O2(g) \longrightarrow 2 H2O(l)$$
 [3.12]

indicate that two molecules of H_2 react with one molecule of O_2 to form two molecules of H_2O . It follows that the relative numbers of moles are identical to the relative numbers of molecules:

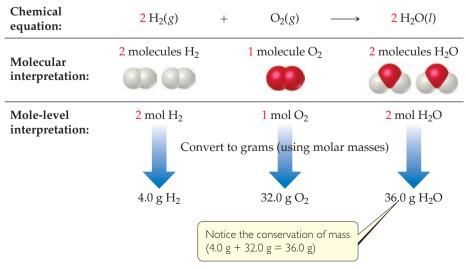

We can generalize this observation to all balanced chemical equations: *The coefficients in a balanced chemical equation indicate both the relative numbers of molecules (or formula units) in the reaction and the relative numbers of moles.* ▼ **Figure 3.15** shows how this result corresponds to the law of conservation of mass.

The quantities 2 mol H_2 , 1 mol O_2 , and 2 mol H_2O given by the coefficients in Equation 3.12 are called *stoichiometrically equivalent quantities*. The relationship between these quantities can be represented as

$$2 \text{ mol } H_2 \cong 1 \text{ mol } O_2 \cong 2 \text{ mol } H_2O$$

where the \simeq symbol means "is stoichiometrically equivalent to." Stoichiometric relations such as these can be used to convert between quantities of reactants and products in a chemical reaction. For example, the number of moles of H_2O produced from 1.57 mol of O_2 is

$$Moles \ H_2O \ = \ (1.57 \ mol \ O_2) \bigg(\frac{2 \ mol \ H_2O}{1 \ mol \ O_2} \bigg) \ = \ 3.14 \ mol \ H_2O$$

▲ Figure 3.15 Interpreting a balanced chemical equation quantitatively.

Give It Some Thought

When 1.57 mol O_2 reacts with H_2 to form H_2O , how many moles of H_2 are consumed in the process?

As an additional example, consider the combustion of butane (C_4H_{10}) , the fuel in disposable lighters:

$$2 C_4 H_{10}(l) + 13 O_2(g) \longrightarrow 8 CO_2(g) + 10 H_2 O(g)$$
 [3.13]

Let's calculate the mass of CO_2 produced when 1.00 g of C_4H_{10} is burned. The coefficients in Equation 3.13 tell us how the amount of C_4H_{10} consumed is related to the amount of CO_2 produced: 2 mol $C_4H_{10} \simeq 8$ mol CO_2 . To use this stoichiometric relationship, we must convert grams of C_4H_{10} to moles using the molar mass of C_4H_{10} , 58.0 g/mol:

Moles
$$C_4H_{10} = (1.00 \text{ g } C_4H_{10}) \left(\frac{1 \text{ mol } C_4H_{10}}{58.0 \text{ g } C_4H_{10}}\right)$$

= $1.72 \times 10^{-2} \text{ mol } C_4H_{10}$

We then use the stoichiometric factor from the balanced equation to calculate moles of CO_2 :

Moles
$$CO_2 = (1.72 \times 10^{-2} \text{ mol } C_4H_{10}) \left(\frac{8 \text{ mol } CO_2}{2 \text{ mol } C_4H_{10}}\right)$$

= $6.88 \times 10^{-2} \text{ mol } CO_2$

Finally, we use the molar mass of CO_2 , 44.0 g/mol, to calculate the CO_2 mass in grams:

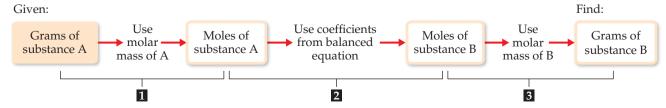

Grams
$$CO_2 = (6.88 \times 10^{-2} \text{ mol } CO_2) \left(\frac{44.0 \text{ g } CO_2}{1 \text{ mol } CO_2}\right)$$

= 3.03 g CO_2

This conversion sequence involves three steps, as illustrated in ▼ Figure 3.16. These three conversions can be combined in a single equation:

$$\begin{split} \text{Grams CO}_2 &= (1.00 \, \text{g C}_4 \text{H}_{10}) \bigg(\frac{1 \, \text{mol C}_4 \text{H}_{10}}{58.0 \, \text{g C}_4 \text{H}_{10}} \bigg) \bigg(\frac{8 \, \text{mol CO}_2}{2 \, \text{mol C}_4 \text{H}_{10}} \bigg) \bigg(\frac{44.0 \, \text{g CO}_2}{1 \, \text{mol CO}_2} \bigg) \\ &= 3.03 \, \text{g CO}_2 \end{split}$$

To calculate the amount of O_2 consumed in the reaction of Equation 3.13, we again rely on the coefficients in the balanced equation for our stoichiometric factor, $2 \text{ mol } C_4H_{10} \cong 13 \text{ mol } O_2$:

▲ Figure 3.16 Procedure for calculating amounts of reactants consumed or products formed in a reaction. The number of grams of a reactant consumed or product formed can be calculated in three steps, starting with the number of grams of any reactant or product.

$$\begin{split} \text{Grams O}_2 &= (1.00 \text{ g C}_4 \text{H}_{10}) \bigg(\frac{1 \text{ mol C}_4 \text{H}_{10}}{58.0 \text{ g C}_4 \text{H}_{10}} \bigg) \bigg(\frac{13 \text{ mol O}_2}{2 \text{ mol C}_4 \text{H}_{10}} \bigg) \bigg(\frac{32.0 \text{ g O}_2}{1 \text{ mol O}_2} \bigg) \\ &= 3.59 \text{ g O}_2 \end{split}$$

Give It Some Thought

In the previous example, 1.00~g of C_4H_{10} reacts with 3.59~g of O_2 to form 3.03~g of CO_2 . Using only addition and subtraction, calculate the amount of H_2O produced.

SAMPLE EXERCISE 3.16 Calculating Amounts of Reactants and Products

Determine how many grams of water are produced in the oxidation of 1.00 g of glucose, C₆H₁₂O₆:

$$C_6H_{12}O_6(s) + 6 O_2(g) \longrightarrow 6 CO_2(g) + 6 H_2O(l)$$

SOLUTION

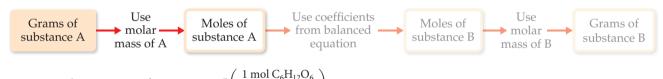

Analyze We are given the mass of a reactant and must determine the mass of a product in the given reaction.

Plan We follow the general strategy outlined in Figure 3.16:

- (1) Convert grams of $C_6H_{12}O_6$ to moles using the molar mass of $C_6H_{12}O_6$.
- (2) Convert moles of $C_6H_{12}O_6$ to moles of H_2O using the stoichiometric relationship 1 mol $C_6H_{12}O_6 \cong 6$ mol H_2O .
- (3) Convert moles of H_2O to grams using the molar mass of H_2O .

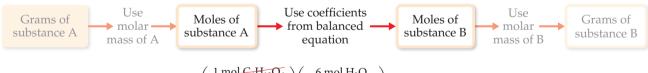

Solve

(1) First we convert grams of $C_6H_{12}O_6$ to moles using the molar mass of $C_6H_{12}O_6$.

Moles
$$C_6H_{12}O_6 = (1.00 \text{ g } C_6H_{12}O_6) \left(\frac{1 \text{ mol } C_6H_{12}O_6}{180.0 \text{ g } C_6H_{12}O_6}\right)$$

(2) Next we convert moles of $C_6H_{12}O_6$ to moles of H_2O using the stoichiometric relationship $1 \text{ mol } C_6H_{12}O_6 \cong 6 \text{ mol } H_2O$.

$$Moles\ H_2O \,=\, (1.00\ g\ C_6H_{\overline{12}}O_6)\bigg(\frac{1\ mol\ C_6H_{\overline{12}}O_6}{180.0\ g\ C_6H_{\overline{12}}O_6}\bigg)\bigg(\frac{6\ mol\ H_2O}{1\ mol\ C_6H_{\overline{12}}O_6}\bigg)$$

(3) Finally, we convert moles of H₂O to grams using the molar mass of H₂O.

$$\begin{split} \text{Grams H}_2\text{O} &= (1.00 \text{ g C}_6\text{H}_{12}\text{O}_6) \bigg(\frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g C}_6\text{H}_{12}\text{O}_6}\bigg) \bigg(\frac{6 \text{ mol H}_2\text{O}}{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}\bigg) \bigg(\frac{18.0 \text{ g H}_2\text{O}}{1 \text{ mol H}_2\text{O}}\bigg) \\ &= 0.600 \text{ g H}_2\text{O} \end{split}$$

Check We can check how reasonable our result is by doing a ballpark estimate of the mass of H_2O . Because the molar mass of glucose is $180 \, \text{g/mol}$, $1 \, \text{g}$ of glucose equals $1/180 \, \text{mol}$. Because 1 mol of glucose yields 6 mol H_2O , we would have $6/180 = 1/30 \, \text{mol}$ H_2O . The molar mass of water is $18 \, \text{g/mol}$, so we have $1/30 \times 18 = 6/10 = 0.6 \, \text{g}$ of H_2O , which agrees with the full calculation. The units, grams H_2O , are correct. The initial data had three significant figures, so three significant figures for the answer is correct.

Practice Exercise 1

Sodium hydroxide reacts with carbon dioxide to form sodium carbonate and water:

$$2 \text{ NaOH}(s) + \text{CO}_2(g) \longrightarrow \text{Na}_2\text{CO}_3(s) + \text{H}_2\text{O}(l)$$

How many grams of Na_2CO_3 can be prepared from 2.40 g of NaOH? (a) 3.18 g, (b) 6.36 g, (c) 1.20 g, (d) 0.0300 g.

Practice Exercise 2

Decomposition of KClO₃ is sometimes used to prepare small amounts of O₂ in the laboratory: $2 \text{ KClO}_3(s) \longrightarrow 2 \text{ KCl}(s) + 3 \text{ O}_2(g)$. How many grams of O₂ can be prepared from 4.50 g of KClO₃?

SAMPLE EXERCISE 3.17

Calculating Amounts of Reactants and Products

Solid lithium hydroxide is used in space vehicles to remove the carbon dioxide gas exhaled by astronauts. The hydroxide reacts with the carbon dioxide to form solid lithium carbonate and liquid water. How many grams of carbon dioxide can be absorbed by 1.00 g of lithium hydroxide?

SOLUTION

Analyze We are given a verbal description of a reaction and asked to calculate the number of grams of one reactant that reacts with $1.00~{\rm g}$ of another.

Plan The verbal description of the reaction can be used to write a balanced equation:

$$2 \operatorname{LiOH}(s) + \operatorname{CO}_2(g) \longrightarrow \operatorname{Li}_2\operatorname{CO}_3(s) + \operatorname{H}_2\operatorname{O}(l)$$

We are given the mass in grams of LiOH and asked to calculate the mass in grams of CO_2 . We can accomplish this with the three conversion steps in Figure 3.16. The conversion of Step 1 requires the molar mass of LiOH ($6.94 + 16.00 + 1.01 = 23.95 \, \text{g/mol}$). The conversion of Step 2 is based on a stoichiometric relationship from the balanced chemical equation: 2 mol LiOH $\stackrel{\frown}{=}$ mol CO_2 . For the Step 3 conversion, we use the molar mass of CO_2 12.01 + 2(16.00) = 44.01 $\, \text{g/mol}$.

Solve

$$(1.00~\text{gLiOH}) \left(\frac{1~\text{molLiOH}}{23.95~\text{gLiOH}}\right) \left(\frac{1~\text{molCO}_2}{2~\text{molLiOH}}\right) \left(\frac{44.01~\text{gCO}_2}{1~\text{molCO}_2}\right) = 0.919~\text{gCO}_2$$

Check Notice that 23.95 g LiOH/mol ≈ 24 g LiOH/mol, 24 g LiOH/mol $\times 2$ mol LiOH = 48 g LiOH, and (44 g CO₂/mol)/(48 g LiOH) is slightly less than 1. Thus, the magnitude of our answer, 0.919 g CO₂, is reasonable based on the amount of starting LiOH. The number of significant figures and units are also appropriate.

Practice Exercise 1

Propane, C_3H_8 (Figure 3.8), is a common fuel used for cooking and home heating. What mass of O_2 is consumed in the combustion of 1.00 g of propane? (a) 5.00 g, (b) 0.726 g, (c) 2.18 g, (d) 3.63 g.

Practice Exercise 2

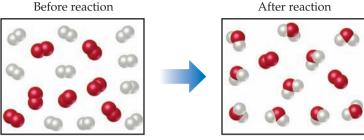

Methanol, CH₃OH, reacts with oxygen from air in a combustion reaction to form water and carbon dioxide. What mass of water is produced in the combustion of 23.6 g of methanol?

3.7 | Limiting Reactants

Suppose you wish to make several sandwiches using one slice of cheese and two slices of bread for each. Using Bd = bread, Ch = cheese, and $Bd_2Ch = sandwich$, the recipe for making a sandwich can be represented like a chemical equation:

$$2 Bd + Ch \longrightarrow Bd_2Ch$$

If you have ten slices of bread and seven slices of cheese, you can make only five sandwiches and will have two slices of cheese left over. The amount of bread available limits the number of sandwiches. If the amount of H₂ is doubled, how many moles of H₂O would have formed?

 $10~\mathrm{H_2}$ and $7~\mathrm{O_2}$ $10~\mathrm{H_2O}$ and $2~\mathrm{O_2}$ (no $\mathrm{H_2}$ molecules)

▲ Figure 3.17 Limiting reactant. Because H_2 is completely consumed, it is the limiting reactant. Because some O_2 is left over after the reaction is complete, it is the excess reactant. The amount of H_2O formed depends on the amount of limiting reactant, H_2 .

An analogous situation occurs in chemical reactions when one reactant is used up before the others. The reaction stops as soon as any reactant is totally consumed, leaving the excess reactants as leftovers. Suppose, for example, we have a mixture of 10 mol H_2 and 7 mol O_2 , which react to form water:

$$2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(g)$$

Because 2 mol $H_2 \cong \text{mol } O_2$, the number of moles of O_2 needed to react with all the H_2 is

Moles
$$O_2 = (10 \text{ mol } H_2) \left(\frac{1 \text{ mol } O_2}{2 \text{ mol } H_2} \right) = 5 \text{ mol } O_2$$

Because 7 mol O_2 is available at the start of the reaction, 7 mol $O_2 - 5$ mol $O_2 = 2$ mol O_2 is still present when all the H_2 is consumed.

The reactant that is completely consumed in a reaction is called the **limiting reactant** because it determines, or limits, the amount of product formed. The other reactants are sometimes called *excess reactants*. In our example, shown in \triangle Figure 3.17, H_2 is the limiting reactant, which means that once all the H_2 has been consumed, the reaction stops. At that point some of the excess reactant O_2 is left over.

There are no restrictions on the starting amounts of reactants in any reaction. Indeed, many reactions are carried out using an excess of one reactant. The quantities of reactants consumed and products formed, however, are restricted by the quantity of the limiting reactant. For example, when a combustion reaction takes place in the open air, oxygen is plentiful and is therefore the excess reactant. If you run out of gasoline while driving, the car stops because the gasoline is the limiting reactant in the combustion reaction that moves the car.

Before we leave the example illustrated in Figure 3.17, let's summarize the data:

	2 H ₂ (g)	+	$O_2(g)$	\longrightarrow	2 H ₂ O(g)
Before reaction:	10 mol		7 mol		0 mol
Change (reaction):	−10 mol		−5 mol		+10 mol
After reaction:	0 mol		2 mol		10 mol

The second line in the table (Change) summarizes the amounts of reactants consumed (where this consumption is indicated by the minus signs) and the amount of the product formed (indicated by the plus sign). These quantities are restricted by the quantity of the limiting reactant and depend on the coefficients in the balanced equation. The mole ratio $H_2:O_2:H_2O=10:5:10$ is a multiple of the ratio of the coefficients in the balanced equation, 2:1:2. The after quantities, which depend on the before quantities and their changes, are found by adding the before quantity and change quantity for each column. The amount of the limiting reactant (H_2) must be zero at the end of the reaction. What remains is 2 mol O_2 (excess reactant) and 10 mol H_2O (product).

SAMPLE EXERCISE 3.18 Calculating the Amount of Product Formed from a Limiting Reactant

The most important commercial process for converting N_2 from the air into nitrogen-containing compounds is based on the reaction of N_2 and H_2 to form ammonia (NH_3):

$$N_2(g) + 3 H_2(g) \longrightarrow 2 NH_3(g)$$

How many moles of NH₃ can be formed from 3.0 mol of N₂ and 6.0 mol of H₂?

SOLUTION

Analyze We are asked to calculate the number of moles of product, NH₃, given the quantities of each reactant, N₂ and H₂, available in a reaction. This is a limiting reactant problem.

Plan If we assume one reactant is completely consumed, we can calculate how much of the second reactant is needed. By comparing the calculated quantity of the second reactant with the amount available, we can determine which reactant is limiting. We then proceed with the calculation, using the quantity of the limiting reactant.

The number of moles of H₂ needed for complete consumption of 3.0 mol of N2 is

Moles
$$H_2 = (3.0 \text{ mol N}_2) \left(\frac{3 \text{ mol H}_2}{1 \text{ mol N}_2} \right) = 9.0 \text{ mol H}_2$$

Because only 6.0 mol H₂ is available, we will run out of H₂ before the N_2 is gone, which tells us that H_2 is the limiting reactant. Therefore, we use the quantity of H₂ to calculate the quantity of NH₃ produced:

$$Moles NH_3 = (6.0 \text{ mol } H_2) \left(\frac{2 \text{ mol } NH_3}{3 \text{ mol } H_2} \right) = 4.0 \text{ mol } NH_3$$

Comment It is useful to summarize the reaction data in a table:

	$N_2(g)$	+ $3 H_2(g)$	\longrightarrow 2 NH ₃ (g)
Before reaction:	3.0 mol	6.0 mol	0 mol
Change (reaction):	-2.0 mol	-6.0 mol	+4.0 mol
After reaction:	1.0 mol	0 mol	4.0 mol

Notice that we can calculate not only the number of moles of NH₃ formed but also the number of moles of each reactant remaining after the reaction. Notice also that although the initial (before) number of moles of H₂ is greater than the final (after) number of moles of N₂, H₂ is nevertheless the limiting reactant because of its larger coefficient in the balanced equation.

Check Examine the Change row of the summary table to see that the mole ratio of reactants consumed and product formed, 2:6:4, is a multiple of the coefficients in the balanced equation, 1:3:2. We confirm that H_2 is the limiting reactant because it is completely consumed in the reaction, leaving 0 mol at the end. Because 6.0 mol H₂ has two significant figures, our answer has two significant figures.

Practice Exercise 1

When 24 mol of methanol and 15 mol of oxygen combine in the combustion reaction $2 \text{ CH}_3 \text{OH}(l) + 3 \text{ O}_2(g)$ $2 CO_2(g) + 4 H_2O(g)$, what is the excess reactant and how many moles of it remains at the end of the reaction? (a) 9 mol CH₃OH(l), (b) 10 mol CO₂(g),

(c) 10 mol CH₃OH(l), (d) 14 mol CH₃OH(l), (e) 1 mol O₂(g).

Practice Exercise 2

(a) When 1.50 mol of Al and 3.00 mol of Cl₂ combine in the reaction 2 Al(s) + 3 Cl₂(g) \longrightarrow 2 AlCl₃(s), which is the limiting reactant? (b) How many moles of AlCl₃ are formed? (c) How many moles of the excess reactant remain at the end of the reaction?

EXERCISE 3.19 Calculating the Amount of Product Formed from a Limiting Reactant

The reaction

$$2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(g)$$

is used to produce electricity in a hydrogen fuel cell. Suppose a fuel cell contains 150 g of $H_2(g)$ and 1500 g of $O_2(g)$ (each measured to two significant figures). How many grams of water can form?

SOLUTION

Analyze We are asked to calculate the amount of a product, given the amounts of two reactants, so this is a limiting reactant problem.

Plan To identify the limiting reactant, we can calculate the number of moles of each reactant and compare their ratio with the ratio of coefficients in the balanced equation. We then use the quantity of the limiting reactant to calculate the mass of water that forms.

Solve From the balanced equation, we have the stoichiometric relations

$$2 \text{ mol } H_2 \cong \text{mol } O_2 \cong 2 \text{ mol } H_2O$$

Using the molar mass of each substance, we calculate the number of moles of each reactant:

Moles
$$H_2 = (150 \text{ gHz}) \left(\frac{1 \text{ mol } H_2}{2.02 \text{ gHz}} \right) = 74 \text{ mol } H_2$$

$$\mathrm{Moles} \ \mathrm{O_2} = (1500 \ \mathrm{g} \ \bigcirc_2) \bigg(\frac{1 \ \mathrm{mol} \ \mathrm{O_2}}{32.0 \ \mathrm{g} \ \bigcirc_2} \bigg) = \ 47 \ \mathrm{mol} \ \mathrm{O_2}$$

The coefficients in the balanced equation indicate that the reaction requires 2 mol of H₂ for every 1 mol of O₂. Therefore, for all the O₂ to completely react, we would need 2 \times 47 = 94 mol of H_2 . Since

there are only 74 mol of H_2 , all of the O_2 cannot react, so it is the excess reactant, and H_2 must be the limiting reactant. (Notice that the limiting reactant is not necessarily the one present in the lowest amount.)

We use the given quantity of H_2 (the limiting reactant) to calculate the quantity of water formed. We could begin this calculation with the given H_2 mass, 150 g, but we can save a step by starting with the moles of H_2 , 74 mol, we just calculated:

Grams
$$H_2O = (74 \text{ mol } H_2) \left(\frac{2 \text{ mol } H_2O}{2 \text{ mol } H_2}\right) \left(\frac{18.0 \text{ g } H_2O}{1 \text{ mol } H_2O}\right)$$

= $1.3 \times 10^2 \text{ g } H_2O$

Check The magnitude of the answer seems reasonable based on the amounts of the reactants. The units are correct, and the number of significant figures (two) corresponds to those in the values given in the problem statement.

Comment The quantity of the limiting reactant, H_2 , can also be used to determine the quantity of O_2 used:

$$\begin{aligned} \text{Grams O}_2 &= (74 \, \text{mol H}_2) \bigg(\frac{1 \, \text{mol O}_2}{2 \, \text{mol H}_2} \bigg) \bigg(\frac{32.0 \, \text{g O}_2}{1 \, \text{mol O}_2} \bigg) \\ &= 1.2 \, \times \, 10^3 \, \text{g O}_2 \end{aligned}$$

The mass of O_2 remaining at the end of the reaction equals the starting amount minus the amount consumed:

$$1500 g - 1200 g = 300 g$$
.

Practice Exercise 1

Molten gallium reacts with arsenic to form the semiconductor, gallium arsenide, GaAs, used in light-emitting diodes and solar cells:

$$Ga(l) + As(s) \longrightarrow GaAs(s)$$

If 4.00 g of gallium is reacted with 5.50 g of arsenic, how many grams of the excess reactant are left at the end of the reaction? (a) 4.94 g As, (b) 0.56 g As, (c) 8.94 g Ga, or (d) 1.50 g As.

Practice Exercise 2

When a 2.00-g strip of zinc metal is placed in an aqueous solution containing 2.50 g of silver nitrate, the reaction is

$$Zn(s) + 2 AgNO_3(aq) \longrightarrow 2 Ag(s) + Zn(NO_3)_2(aq)$$

(a) Which reactant is limiting? (b) How many grams of Ag form? (c) How many grams of Zn(NO₃)₂ form? (d) How many grams of the excess reactant are left at the end of the reaction?

Theoretical and Percent Yields

The quantity of product calculated to form when all of a limiting reactant is consumed is called the **theoretical yield**. The amount of product actually obtained, called the *actual yield*, is almost always less than (and can never be greater than) the theoretical yield. There are many reasons for this difference. Part of the reactants may not react, for example, or they may react in a way different from that desired (side reactions). In addition, it is not always possible to recover all of the product from the reaction mixture. The **percent yield** of a reaction relates actual and theoretical yields:

Percent yield =
$$\frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$$
 [3.14]

SAMPLE EXERCISE 3.20 Calculating Theoretical Yield and Percent Yield

Adipic acid, $H_2C_6H_8O_4$, used to produce nylon, is made commercially by a reaction between cyclohexane (C_6H_{12}) and O_2 :

$$2 C_6 H_{12}(l) + 5 O_2(g) \longrightarrow 2 H_2 C_6 H_8 O_4(l) + 2 H_2 O(g)$$

(a) Assume that you carry out this reaction with 25.0 g of cyclohexane and that cyclohexane is the limiting reactant. What is the theoretical yield of adipic acid? (b) If you obtain 33.5 g of adipic acid, what is the percent yield for the reaction?

SOLUTION

Analyze We are given a chemical equation and the quantity of the limiting reactant (25.0 g of C_6H_{12}). We are asked to calculate the theoretical yield of a product $H_2C_6H_8O_4$ and the percent yield if only 33.5 g of product is obtained.

Plan

- (a) The theoretical yield, which is the calculated quantity of adipic acid formed, can be calculated using the sequence of conversions shown in Figure 3.16.
- (b) The percent yield is calculated by using Equation 3.14 to compare the given actual yield (33.5 g) with the theoretical yield.

Solve

(a) The theoretical yield is

$$\begin{split} \text{Grams H}_2\text{C}_6\text{H}_8\text{O}_4 &= (25.0 \text{ g C}_6\text{H}_{12}) \bigg(\frac{1 \text{ mol C}_6\text{H}_{12}}{84.0 \text{ g C}_6\text{H}_{12}}\bigg) \bigg(\frac{2 \text{ mol H}_2\text{C}_6\text{H}_8\text{O}_4}{2 \text{ mol C}_6\text{H}_{12}}\bigg) \bigg(\frac{146.0 \text{ g H}_2\text{C}_6\text{H}_8\text{O}_4}{1 \text{ mol H}_2\text{C}_6\text{H}_8\text{O}_4}\bigg) \\ &= 43.5 \text{ g H}_2\text{C}_6\text{H}_8\text{O}_4 \end{split}$$

(b) Percent yield =
$$\frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% = \frac{33.5 \text{ g}}{43.5 \text{ g}} \times 100\% = 77.0\%$$

Check We can check our answer in (a) by doing a ballpark calculation. From the balanced equation we know that each mole of cyclohexane gives 1 mol adipic acid. We have $25/84 \approx 25/75 = 0.3$ mol hexane, so we expect 0.3 mol adipic acid, which equals about $0.3 \times 150 = 45$ g, about the same magnitude as the 43.5 g obtained in the more detailed calculation given previously. In addition, our answer has the appropriate units and number of significant figures. In (b) the answer is less than 100%, as it must be from the definition of percent yield.

Practice Exercise 1

If 3.00 g of titanium metal is reacted with 6.00 g of chlorine gas, Cl₂, to form 7.7 g of titanium (IV) chloride in a combination reaction, what is the percent yield of the product? (a) 65%, (b) 96%, (c) 48%, or (d) 86%.

Practice Exercise 2

Imagine you are working on ways to improve the process by which iron ore containing Fe₂O₃ is converted into iron:

$$Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g)$$

- (a) If you start with 150 g of Fe₂O₃ as the limiting reactant, what is the theoretical yield of Fe?
- (b) If your actual yield is 87.9 g, what is the percent yield?

Strategies in Chemistry

Design an Experiment

One of the most important skills you can learn in school is how to think like a scientist. Questions such as: "What experiment might test this hypothesis?", "How do I interpret these data?", and "Do these data support the hypothesis?" are asked every day by chemists and other scientists as they go about their work.

We want you to become a good critical thinker as well as an active, logical, and curious learner. For this purpose, starting in Chapter 3, we include at the end of each chapter a special exercise called "Design an Experiment." Here is an example:

Is milk a pure liquid or a mixture of chemical components in water? Design an experiment to distinguish between these two possibilities.

You might already know the answer—milk is indeed a mixture of components in water—but the goal is to think of how to demonstrate this in practice. Upon thinking about it, you will likely realize that the key idea for this experiment is separation: You can prove that milk is a mixture of chemical components if you can figure out how to separate these components.

Testing a hypothesis is a creative endeavor. While some experiments may be more efficient than others, there is often more than one good way to test a hypothesis. Our question about milk, for example, might be explored by an experiment in which you boil a known quantity of milk until it is dry. Does a solid residue form in the bottom

of the pan? If so, you could weigh it, and calculate the percentage of solids in milk, which would offer good evidence that milk is a mixture. If there is no residue after boiling, then you still cannot distinguish between the two possibilities.

What other experiments might you do to demonstrate that milk is a mixture? You could put a sample of milk in a centrifuge, which you might have used in a biology lab, spin your sample and observe if any solids collect at the bottom of the centrifuge tube; large molecules can be separated in this way from a mixture. Measurement of the mass of the solid at the bottom of the tube is a way to obtain a value for the % solids in milk, and also tells you that milk is indeed a mixture.

Keep an open mind: Lacking a centrifuge, how else might you separate solids in the milk? You could consider using a filter with really tiny holes in it or perhaps even a fine strainer. You could propose that if milk were poured through this filter, some (large) solid components should stay on the top of the filter, while water (and really small molecules or ions) would pass through the filter. That result would be evidence that milk is a mixture. Does such a filter exist? Yes! But for our purposes, the existence of such a filter is not the point: the point is, can you use your imagination and your knowledge of chemistry to design a reasonable experiment? Don't worry too much about the exact apparatus you need for the "Design an Experiment" exercises. The goal is to imagine what you would need to do, or what kind of data would you need to collect, in order to answer the question. If your

instructor allows it, you can collaborate with others in your class to develop ideas. Scientists discuss their ideas with other scientists all the time. We find that discussing ideas, and refining them, makes us better scientists and helps us collectively answer important questions.

The design and interpretation of scientific experiments is at the heart of the scientific method. Think of the Design an Experiment exercises as puzzles that can be solved in various ways, and enjoy your explorations!

Chapter Summary and Key Terms

CHEMICAL EQUATIONS (INTRODUCTION AND SECTION 3.1)

The study of the quantitative relationships between chemical formulas and chemical equations is known as **stoichiometry**. One of the important concepts of stoichiometry is the **law of conservation of mass**, which states that the total mass of the products of a chemical reaction is the same as the total mass of the reactants. The same numbers of atoms of each type are present before and after a chemical reaction. A balanced **chemical equation** shows equal numbers of atoms of each element on each side of the equation. Equations are balanced by placing coefficients in front of the chemical formulas for the **reactants** and **products** of a reaction, *not* by changing the subscripts in chemical formulas.

SIMPLE PATTERNS OF CHEMICAL REACTIVITY (SECTION 3.2)

Among the reaction types described in this chapter are (1) combination reactions, in which two reactants combine to form one product; (2) decomposition reactions, in which a single reactant forms two or more products; and (3) combustion reactions in oxygen, in which a substance, typically a hydrocarbon, reacts rapidly with O_2 to form CO_2 and H_2O .

FORMULA WEIGHTS (SECTION 3.3) Much quantitative information can be determined from chemical formulas and balanced chemical equations by using atomic weights. The formula weight of a compound equals the sum of the atomic weights of the atoms in its formula. If the formula is a molecular formula, the formula weight is also called the molecular weight. Atomic weights and formula weights can be used to determine the elemental composition of a compound.

AVOGADRO'S NUMBER AND THE MOLE (SECTION 3.4) A mole of any substance contains **Avogadro's number** (6.02×10^{23}) of formula

units of that substance. The mass of a **mole** of atoms, molecules, or ions (the **molar mass**) equals the formula weight of that material expressed in grams. The mass of one molecule of H_2O , for example, is 18.0 amu, so the mass of 1 mol of H_2O is 18.0 g. That is, the molar mass of H_2O is 18.0 g/mol.

EMPIRICAL FORMULAS FROM ANALYSIS (SECTION 3.5) The empirical formula of any substance can be determined from its percent composition by calculating the relative number of moles of each atom in 100 g of the substance. If the substance is molecular in nature, its molecular formula can be determined from the empirical formula if the molecular weight is also known. Combustion analysis is a special technique for determining the empirical formulas of compounds containing only carbon, hydrogen, and/or oxygen.

QUANTITATIVE INFORMATION FROM BALANCED EQUATIONS AND LIMITING REACTANTS (SECTIONS 3.6 AND 3.7) The mole concept can be used to calculate the relative quantities of reactants and products in chemical reactions. The coefficients in a balanced equation give the relative numbers of moles of the reactants and products. To calculate the number of grams of a product from the number of grams of a reactant, first convert grams of reactant to moles of reactant. Then use the coefficients in the balanced equation to convert the number of moles of reactant to moles of product. Finally, convert moles of product to grams of product.

A **limiting reactant** is completely consumed in a reaction. When it is used up, the reaction stops, thus limiting the quantities of products formed. The **theoretical yield** of a reaction is the quantity of product calculated to form when all of the limiting reactant reacts. The actual yield of a reaction is always less than the theoretical yield. The **percent yield** compares the actual and theoretical yields.

Learning Outcomes After studying this chapter, you should be able to:

- Balance chemical equations. (Section 3.1)
- Predict the products of simple combination, decomposition, and combustion reactions. (Section 3.2)
- Calculate formula weights. (Section 3.3)
- Convert grams to moles and vice versa using molar masses. (Section 3.4)
- Convert number of molecules to moles and vice versa using Avogadro's number. (Section 3.4)
- Calculate the empirical and molecular formulas of a compound from percentage composition and molecular weight. (Section 3.5)
- Identify limiting reactants and calculate amounts, in grams or moles, of reactants consumed and products formed for a reaction. (Section 3.6)
- Calculate the percent yield of a reaction. (Section 3.7)

Key Equations

• Elemental composition (%) =
$$\frac{\left(\begin{array}{c} \text{number of atoms} \\ \text{of that element} \end{array}\right) \left(\begin{array}{c} \text{atomic weight} \\ \text{of element} \end{array}\right)}{\text{formula weight of compound}} \times 100\%$$

This is the formula to calculate the mass percentage of each element in a compound. The sum of all the percentages of all the elements in a compound should add up to 100%.

• Percent yield =
$$\frac{\text{(actual yield)}}{\text{(theoretical yield)}} \times 100\%$$

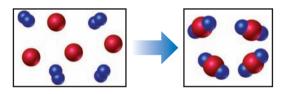

[3.14] This is the formula to calculate the percent yield of a reaction. The percent yield can never be more than 100%.

[3.10]

Exercises

Visualizing Concepts

3.1 The reaction between reactant A (blue spheres) and reactant B (red spheres) is shown in the following diagram:

Based on this diagram, which equation best describes the reaction? [Section 3.1]

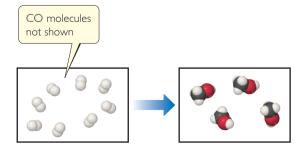

$$(a) A_2 + B \longrightarrow A_2B$$

(b)
$$A_2 + 4B \longrightarrow 2AB_2$$

(c)
$$2 A + B_4 \longrightarrow 2 AB_2$$

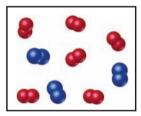

(d)
$$A + B_2 \longrightarrow AB_2$$

- **3.2** The following diagram shows the combination reaction between hydrogen, H₂, and carbon monoxide, CO, to produce methanol, CH₃OH (white spheres are H, black spheres are C, red spheres are O). The correct number of CO molecules involved in this reaction is not shown. [Section 3.1]
 - (a) Determine the number of CO molecules that should be shown in the left (reactants) box.
 - **(b)** Write a balanced chemical equation for the reaction.

3.3 The following diagram represents the collection of elements formed by a decomposition reaction. (a) If the blue spheres represent N atoms and the red ones represent O atoms, what was the empirical formula of the original compound? (b) Could you

draw a diagram representing the molecules of the compound that had been decomposed? Why or why not? [Section 3.2]

3.4 The following diagram represents the collection of CO₂ and H₂O molecules formed by complete combustion of a hydrocarbon. What is the empirical formula of the hydrocarbon? [Section 3.2]

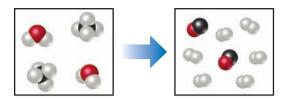

- 3.5 Glycine, an amino acid used by organisms to make proteins, is represented by the following molecular model.
 - (a) Write its molecular formula.
 - (b) Determine its molar mass.
 - (c) Calculate the mass of 3 mol of glycine.
 - (d) Calculate the percent nitrogen by mass in glycine. [Sections 3.3 and 3.5]

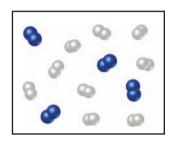

113

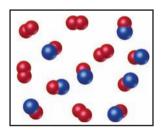

3.6 The following diagram represents a high-temperature reaction between CH₄ and H₂O. Based on this reaction, find how many moles of each product can be obtained starting with 4.0 mol CH₄. [Section 3.6]

3.7 Nitrogen (N_2) and hydrogen (H_2) react to form ammonia (NH_3) . Consider the mixture of N_2 and H_2 shown in the accompanying diagram. The blue spheres represent N, and the white ones represent H. Draw a representation of the product mixture, assuming that the reaction goes to completion. How did you arrive at your representation? What is the limiting reactant in this case? [Section 3.7]

3.8 Nitrogen monoxide and oxygen react to form nitrogen dioxide. Consider the mixture of NO and O₂ shown in the accompanying diagram. The blue spheres represent N, and the red ones represent O. (a) Draw a representation of the product mixture, assuming that the reaction goes to completion. What is the limiting reactant in this case? (b) How many NO₂ molecules would you draw as products if the reaction had a percent yield of 75%? [Section 3.7]

Chemical Equations and Simple Patterns of Chemical Reactivity (Sections 3.1 and 3.2)

- **3.9** (a) What scientific principle or law is used in the process of balancing chemical equations? (b) In balancing equations is it acceptable to change the coefficients, the subscripts in the chemical formula, or both?
- **3.10** A key step in balancing chemical equations is correctly identifying the formulas of the reactants and products. For example, consider the reaction between calcium oxide, CaO(s), and $H_2O(l)$ to form aqueous calcium hydroxide. (a) Write a balanced chemical equation for this combination reaction, having correctly identified the product as $Ca(OH)_2(aq)$. (b) Is it possible to balance the equation if you incorrectly identify the product as CaOH(aq), and if so, what is the equation?

- **3.11** Balance the following equations:
 - (a) $CO(g) + O_2(g) \longrightarrow CO_2(g)$
 - **(b)** $N_2O_5(g) + H_2O(l) \longrightarrow HNO_3(aq)$
 - (c) $CH_4(g) + Cl_2(g) \longrightarrow CCl_4(l) + HCl(g)$
 - (d) $\operatorname{Zn}(\operatorname{OH})_2(s) + \operatorname{HNO}_3(aq) \longrightarrow \operatorname{Zn}(\operatorname{NO}_3)_2(aq) + \operatorname{H}_2\operatorname{O}(l)$
- **3.12** Balance the following equations:
 - (a) $Li(s) + N_2(g) \longrightarrow Li_3N(s)$
 - **(b)** $\operatorname{TiCl}_4(l) + \operatorname{H}_2\operatorname{O}(l) \longrightarrow \operatorname{TiO}_2(s) + \operatorname{HCl}(aq)$
 - (c) $NH_4NO_3(s) \longrightarrow N_2(g) + O_2(g) + H_2O(g)$
 - (d) $AlCl_3(s) + Ca_3N_2(s) \longrightarrow AlN(s) + CaCl_2(s)$
- **3.13** Balance the following equations:
 - (a) $Al_4C_3(s) + H_2O(l) \longrightarrow Al(OH)_3(s) + CH_4(g)$
 - (b) $C_5H_{10}O_2(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$
 - (c) $\operatorname{Fe}(OH)_3(s) + \operatorname{H}_2SO_4(aq) \longrightarrow \operatorname{Fe}_2(SO_4)_3(aq) + \operatorname{H}_2O(l)$
 - (d) $Mg_3N_2(s) + H_2SO_4(aq) \longrightarrow MgSO_4(aq) + (NH_4)_2SO_4(aq)$
- **3.14** Balance the following equations:
 - (a) $Ca_3P_2(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq) + PH_3(g)$
 - **(b)** $Al(OH)_3(s) + H_2SO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + H_2O(l)$
 - (c) $AgNO_3(aq) + Na_2CO_3(aq) \longrightarrow Ag_2CO_3(s) + NaNO_3(aq)$
 - (d) $C_2H_5NH_2(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g) + N_2(g)$
- 3.15 Write balanced chemical equations corresponding to each of the following descriptions: (a) Solid calcium carbide, CaC₂, reacts with water to form an aqueous solution of calcium hydroxide and acetylene gas, C₂H₂. (b) When solid potassium chlorate is heated, it decomposes to form solid potassium chloride and oxygen gas. (c) Solid zinc metal reacts with sulfuric acid to form hydrogen gas and an aqueous solution of zinc sulfate. (d) When liquid phosphorus trichloride is added to water, it reacts to form aqueous phosphorous acid, H₃PO₃(aq), and aqueous hydrochloric acid. (e) When hydrogen sulfide gas is passed over solid hot iron(III) hydroxide, the resultant reaction produces solid iron(III) sulfide and gaseous water.
- 3.16 Write balanced chemical equations to correspond to each of the following descriptions: (a) When sulfur trioxide gas reacts with water, a solution of sulfuric acid forms. b) Boron sulfide, B₂S₃(s), reacts violently with water to form dissolved boric acid, H₃BO₃, and hydrogen sulfide gas. (c) Phosphine, PH₃(g), combusts in oxygen gas to form water vapor and solid tetraphosphorus decaoxide. (d) When solid mercury(II) nitrate is heated, it decomposes to form solid mercury(II) oxide, gaseous nitrogen dioxide, and oxygen. (e) Copper metal reacts with hot concentrated sulfuric acid solution to form aqueous copper(II) sulfate, sulfur dioxide gas, and water.

Patterns of Chemical Reactivity (Section 3.2)

- 3.17 (a) When the metallic element sodium combines with the nonmetallic element bromine, Br₂(l), what is the chemical formula of the product? (b) Is the product a solid, liquid, or gas at room temperature? (c) In the balanced chemical equation for this reaction, what is the coefficient in front of the product?
- **3.18** (a) When a compound containing C, H, and O is completely combusted in air, what reactant besides the hydrocarbon is involved in the reaction? (b) What products form in

this reaction? (c) What is the sum of the coefficients in the balanced chemical equation for the combustion of acetone, $C_3H_6O(l)$, in air?

- **3.19** Write a balanced chemical equation for the reaction that occurs when (a) Mg(s) reacts with $Cl_2(g)$; (b) barium carbonate decomposes into barium oxide and carbon dioxide gas when heated; (c) the hydrocarbon styrene, $C_8H_8(l)$, is combusted in air; (d) dimethylether, $CH_3OCH_3(g)$, is combusted in air.
- **3.20** Write a balanced chemical equation for the reaction that occurs when (a) titanium metal undergoes a combination reaction with $O_2(g)$; (b) silver(I) oxide decomposes into silver metal and oxygen gas when heated; (c) propanol, $C_3H_7OH(l)$ burns in air; (d) methyl tert-butyl ether, $C_5H_{12}O(l)$, burns in air.
- **3.21** Balance the following equations and indicate whether they are combination, decomposition, or combustion reactions:

(a)
$$C_3H_6(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

(b)
$$NH_4NO_3(s) \longrightarrow N_2O(g) + H_2O(g)$$

(c)
$$C_5H_6O(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

(d)
$$N_2(g) + H_2(g) \longrightarrow NH_3(g)$$

(e)
$$K_2O(s) + H_2O(l) \longrightarrow KOH(aq)$$

3.22 Balance the following equations and indicate whether they are combination, decomposition, or combustion reactions:

(a)
$$PbCO_3(s) \longrightarrow PbO(s) + CO_2(g)$$

(b)
$$C_2H_4(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

(c)
$$Mg(s) + N_2(g) \longrightarrow Mg_3N_2(s)$$

(d)
$$C_7H_8O_2(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

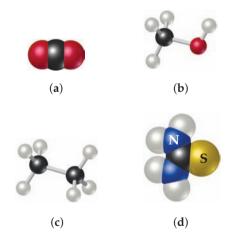

(e)
$$Al(s) + Cl_2(g) \longrightarrow AlCl_3(s)$$

Formula Weights (Section 3.3)

- 3.23 Determine the formula weights of each of the following compounds: (a) nitric acid, HNO₃; (b) KMnO₄; (c) Ca₃(PO₄)₂; (d) quartz, SiO₂; (e) gallium sulfide, (f) chromium(III) sulfate, (g) phosphorus trichloride.
- **3.24** Determine the formula weights of each of the following compounds: (a) nitrous oxide, N₂O, known as laughing gas and used as an anesthetic in dentistry; (b) benzoic acid; HC₇H₅O₂, a substance used as a food preservative; (c) Mg(OH)₂, the active ingredient in milk of magnesia; (d) urea, (NH₂)₂CO, a compound used as a nitrogen fertilizer; (e) isopentyl acetate, CH₃CO₂C₅H₁₁, responsible for the odor of bananas.
- 3.25 Calculate the percentage by mass of oxygen in the following compounds: (a) morphine, $C_{17}H_{19}NO_3$; (b) codeine, $C_{18}H_{21}NO_3$ (c) cocaine, $C_{17}H_{21}NO_4$; (d) tetracycline, $C_{22}H_{24}N_2O_8$; (e) digitoxin, $C_{41}H_{64}O_{13}$; (f) vancomycin, $C_{66}H_{75}Cl_2N_9O_{24}$.
- 3.26 Calculate the percentage by mass of the indicated element in the following compounds: (a) carbon in acetylene, C₂H₂, a gas used in welding; (b) hydrogen in ascorbic acid, HC₆H₇O₆, also known as vitamin C; (c) hydrogen in ammonium sulfate, (NH₄)₂SO₄, a substance used as a nitrogen fertilizer; (d) platinum in PtCl₂(NH₃)₂, a chemotherapy agent called cisplatin; (e) oxygen in the female sex hormone estradiol, C₁₈H₂₄O₂; (f) carbon in capsaicin, C₁₈H₂₇NO₃, the compound that gives the hot taste to chili peppers.

3.27 Based on the following structural formulas, calculate the percentage of carbon by mass present in each compound:

3.28 Calculate the percentage of carbon by mass in each of the compounds represented by the following models:

Avogadro's Number and the Mole (Section 3.4)

- 3.29 (a) The world population is estimated to be approximately7 billion people. How many moles of people are there?(b) What units are typically used to express formula weight?(c) What units are typically used to express molar mass?
- **3.30** (a) What is the mass, in grams, of a mole of ¹²C? (b) How many carbon atoms are present in a mole of ¹²C?
- 3.31 Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing numbers of atoms: 0.50 mol H_2O , 23 g Na, 6.0 \times 10²³ N_2 molecules.

- 3.32 Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing numbers of atoms: 42 g of NaHCO₃, 1.5 mol CO₂, 6.0×10^{24} Ne atoms.
- 3.33 What is the mass, in kilograms, of an Avogadro's number of people, if the average mass of a person is 160 lb? How does this compare with the mass of Earth, 5.98×10^{24} kg?
- 3.34 If Avogadro's number of pennies is divided equally among the 314 million men, women, and children in the United States, how many dollars would each receive? How does this compare with the gross domestic product (GDP) of the United States, which was \$15.1 trillion in 2011? (The GDP is the total market value of the nation's goods and services.)
- **3.35** Calculate the following quantities:
 - (a) mass, in grams, of 0.105 mol sucrose $(C_{12}H_{22}O_{11})$
 - (b) moles of $Zn(NO_3)_2$ in 143.50 g of this substance
 - (c) number of molecules in 1.0×10^{-6} mol CH₃CH₂OH
 - (d) number of N atoms in 0.410 mol NH₃
- 3.36 Calculate the following quantities:
 - (a) mass, in grams, of 1.50×10^{-2} mol CdS
 - (b) number of moles of NH₄Cl in 86.6 g of this substance
 - (c) number of molecules in 8.447×10^{-2} mol C₆H₆
 - (d) number of O atoms in 6.25×10^{-3} mol Al(NO₃)₃
- **3.37 (a)** What is the mass, in grams, of 2.50×10^{-3} mol of ammonium phosphate?
 - **(b)** How many moles of chloride ions are in 0.2550 g of aluminum chloride?
 - (c) What is the mass, in grams, of 7.70×10^{20} molecules of caffeine, $C_8H_{10}N_4O_2$?
 - (d) What is the molar mass of cholesterol if 0.00105 mol has a mass of 0.406 g?
- 3.38 (a) What is the mass, in grams, of 1.223 mol of iron (III) sulfate?
 - **(b)** How many moles of ammonium ions are in 6.955 g of ammonium carbonate?
 - (c) What is the mass, in grams, of 1.50 \times 10²¹ molecules of aspirin, $C_9H_8O_4$?
 - (d) What is the molar mass of diazepam (Valium®) if 0.05570 mol has a mass of 15.86 g?
- **3.39** The molecular formula of allicin, the compound responsible for the characteristic smell of garlic, is $C_6H_{10}OS_2$. (a) What is the molar mass of allicin? (b) How many moles of allicin are present in 5.00 mg of this substance? (c) How many molecules of allicin are in 5.00 mg of this substance? (d) How many S atoms are present in 5.00 mg of allicin?
- 3.40 The molecular formula of aspartame, the artificial sweetener marketed as NutraSweet®, is C₁₄H₁₈N₂O₅. (a) What is the molar mass of aspartame? (b) How many moles of aspartame are present in 1.00 mg of aspartame? (c) How many molecules of aspartame are present in 1.00 mg of aspartame? (d) How many hydrogen atoms are present in 1.00 mg of aspartame?
- **3.41** A sample of glucose, $C_6H_{12}O_6$, contains 1.250×10^{21} carbon atoms. (a) How many atoms of hydrogen does it contain? (b) How many molecules of glucose does it contain? (c) How

- many moles of glucose does it contain? (d) What is the mass of this sample in grams?
- **3.42** A sample of the male sex hormone testosterone, $C_{19}H_{28}O_2$, contains 3.88×10^{21} hydrogen atoms. (a) How many atoms of carbon does it contain? (b) How many molecules of testosterone does it contain? (c) How many moles of testosterone does it contain? (d) What is the mass of this sample in grams?
- **3.43** The allowable concentration level of vinyl chloride, C_2H_3Cl , in the atmosphere in a chemical plant is 2.0×10^{-6} g/L. How many moles of vinyl chloride in each liter does this represent? How many molecules per liter?
- **3.44** At least 25 μ g of tetrahydrocannabinol (THC), the active ingredient in marijuana, is required to produce intoxication. The molecular formula of THC is $C_{21}H_{30}O_2$. How many moles of THC does this 25 μ g represent? How many molecules?

Empirical Formulas from Analyses (Section 3.5)

- 3.45 Give the empirical formula of each of the following compounds if a sample contains (a) 0.0130 mol C, 0.0390 mol H, and 0.0065 mol O; (b) 11.66 g iron and 5.01 g oxygen; (c) 40.0% C, 6.7% H, and 53.3% O by mass.
- **3.46** Determine the empirical formula of each of the following compounds if a sample contains (a) 0.104 mol K, 0.052 mol C, and 0.156 mol O; (b) 5.28 g Sn and 3.37 g F; (c) 87.5% N and 12.5% H by mass.
- **3.47** Determine the empirical formulas of the compounds with the following compositions by mass:
 - (a) 10.4% C, 27.8% S, and 61.7% Cl
 - **(b)** 21.7% C, 9.6% O, and 68.7% F
 - (c) 32.79% Na, 13.02% Al, and the remainder F
- **3.48** Determine the empirical formulas of the compounds with the following compositions by mass:
 - (a) 55.3% K, 14.6% P, and 30.1% O
 - **(b)** 24.5% Na, 14.9% Si, and 60.6% F
 - (c) 62.1% C, 5.21% H, 12.1% N, and the remainder O
- **3.49** A compound whose empirical formula is XF₃ consists of 65% F by mass. What is the atomic mass of X?
- **3.50** The compound XCl_4 contains 75.0% Cl by mass. What is the element X?
- **3.51** What is the molecular formula of each of the following compounds?
 - (a) empirical formula CH_2 , molar mass = 84 g/mol
 - (b) empirical formula NH₂Cl, molar mass = 51.5 g/mol
- **3.52** What is the molecular formula of each of the following compounds?
 - (a) empirical formula HCO_2 , molar mass = 90.0 g/mol
 - (b) empirical formula C_2H_4O , molar mass = 88 g/mol
- **3.53** Determine the empirical and molecular formulas of each of the following substances:
 - (a) Styrene, a compound substance used to make Styrofoam® cups and insulation, contains 92.3% C and 7.7% H by mass and has a molar mass of 104 g/mol.

- (b) Caffeine, a stimulant found in coffee, contains 49.5% C, 5.15% H, 28.9% N, and 16.5% O by mass and has a molar mass of 195 g/mol.
- (c) Monosodium glutamate (MSG), a flavor enhancer in certain foods, contains 35.51% C, 4.77% H, 37.85% O, 8.29% N, and 13.60% Na, and has a molar mass of 169 g/mol.
- **3.54** Determine the empirical and molecular formulas of each of the following substances:
 - (a) Ibuprofen, a headache remedy, contains 75.69% C, 8.80% H, and 15.51% O by mass, and has a molar mass of 206 g/mol.
 - (b) Cadaverine, a foul-smelling substance produced by the action of bacteria on meat, contains 58.55% C, 13.81% H, and 27.40% N by mass; its molar mass is 102.2 g/mol.
 - (c) Epinephrine (adrenaline), a hormone secreted into the bloodstream in times of danger or stress, contains 59.0% C, 7.1% H, 26.2% O, and 7.7% N by mass; its MW is about 180 amu.
- 3.55 (a) Combustion analysis of toluene, a common organic solvent, gives 5.86 mg of CO₂ and 1.37 mg of H₂O. If the compound contains only carbon and hydrogen, what is its empirical formula? (b) Menthol, the substance we can smell in mentholated cough drops, is composed of C, H, and O. A 0.1005-g sample of menthol is combusted, producing 0.2829 g of CO₂ and 0.1159 g of H₂O. What is the empirical formula for menthol? If menthol has a molar mass of 156 g/mol, what is its molecular formula?
- **3.56** (a) The characteristic odor of pineapple is due to ethyl butyrate, a compound containing carbon, hydrogen, and oxygen. Combustion of 2.78 mg of ethyl butyrate produces 6.32 mg of CO_2 and 2.58 mg of CO_2 and 3.50 mg of CO_2 and 3.60 Nicotine, a component of tobacco, is composed of CO_2 and CO_2 and
- 3.57 Valproic acid, used to treat seizures and bipolar disorder, is composed of C, H, and O. A 0.165-g sample is combusted in an apparatus such as that shown in Figure 3.14. The gain in mass of the $\rm H_2O$ absorber is 0.166 g, whereas that of the $\rm CO_2$ absorber is 0.403 g. What is the empirical formula for valproic acid? If the molar mass is 144 g/mol what is the molecular formula?
- 3.58 Propenoic acid is a reactive organic liquid used in the manufacture of plastics, coatings, and adhesives. An unlabeled container is thought to contain this acid. A 0.2033-g sample is combusted in an apparatus such as that shown in Figure 3.14. The gain in mass of the $\rm H_2O$ absorber is 0.102 g, whereas that of the $\rm CO_2$ absorber is 0.374 g. What is the empirical formula of propenoic acid?
- **3.59** Washing soda, a compound used to prepare hard water for washing laundry, is a hydrate, which means that a certain number of water molecules are included in the solid structure. Its formula can be written as Na₂CO₃ ⋅ *x*H₂O, where *x* is the number of moles of H₂O per mole of Na₂CO₃. When a 2.558-g sample of washing soda is heated at 125 °C, all the water of hydration is lost, leaving 0.948 g of Na₂CO₃. What is the value of *x*?
- **3.60** Epsom salts, a strong laxative used in veterinary medicine, is a hydrate, which means that a certain number of water molecules are included in the solid structure. The formula for Epsom salts can be written as $MgSO_4 \cdot xH_2O$, where x indicates the number

of moles of H_2O per mole of MgSO₄. When 5.061 g of this hydrate is heated to 250 °C, all the water of hydration is lost, leaving 2.472 g of MgSO₄. What is the value of x?

Quantitative Information from Balanced Equations (Section 3.6)

3.61 Hydrofluoric acid, HF(*aq*), cannot be stored in glass bottles because compounds called silicates in the glass are attacked by the HF(*aq*). Sodium silicate (Na₂SiO₃), for example, reacts as follows:

$$Na_2SiO_3(s) + 8 HF(aq) \longrightarrow H_2SiF_6(aq) + 2 NaF(aq) + 3 H_2O(l)$$

- (a) How many moles of HF are needed to react with 0.300 mol of Na₂SiO₃?
- **(b)** How many grams of NaF form when 0.500 mol of HF reacts with excess Na₂SiO₃?
- (c) How many grams of Na₂SiO₃ can react with 0.800 g of HF?
- **3.62** The reaction between potassium superoxide, KO_2 , and CO_2 ,

$$4 \text{ KO}_2 + 2 \text{ CO}_2 \longrightarrow 2 \text{K}_2 \text{CO}_3 + 3 \text{ O}_2$$

is used as a source of O₂ and absorber of CO₂ in self-contained breathing equipment used by rescue workers.

- (a) How many moles of O₂ are produced when 0.400 mol of KO₂ reacts in this fashion?
- **(b)** How many grams of KO₂ are needed to form 7.50 g of O₂?

- (c) How many grams of CO₂ are used when 7.50 g of O₂ are produced?
- **3.63** Several brands of antacids use Al(OH)₃ to react with stomach acid, which contains primarily HCl:

$$Al(OH)_3(s) + HCl(aq) \longrightarrow AlCl_3(aq) + H_2O(l)$$

- (a) Balance this equation.
- (b) Calculate the number of grams of HCl that can react with 0.500~g of Al(OH)₃.
- (c) Calculate the number of grams of AlCl₃ and the number of grams of H₂O formed when 0.500 g of Al(OH)₃ reacts.
- (d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.
- **3.64** An iron ore sample contains Fe_2O_3 together with other substances. Reaction of the ore with CO produces iron metal:

$$Fe_2O_3(s) + CO(g) \longrightarrow Fe(s) + CO_2(g)$$

- (a) Balance this equation.
- (b) Calculate the number of grams of CO that can react with 0.350 kg of Fe_2O_3 .
- (c) Calculate the number of grams of Fe and the number of grams of CO_2 formed when 0.350 kg of Fe_2O_3 reacts.
- (d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

117

- 3.65 Aluminum sulfide reacts with water to form aluminum hydroxide and hydrogen sulfide. (a) Write the balanced chemical equation for this reaction. (b) How many grams of aluminum hydroxide are obtained from 14.2 g of aluminum sulfide?
- 3.66 Calcium hydride reacts with water to form calcium hydroxide and hydrogen gas. (a) Write a balanced chemical equation for the reaction. (b) How many grams of calcium hydride are needed to form 4.500 g of hydrogen?
- 3.67 Automotive air bags inflate when sodium azide, NaN₃, rapidly decomposes to its component elements:

$$2 \operatorname{NaN}_3(s) \longrightarrow 2 \operatorname{Na}(s) + 3 \operatorname{N}_2(g)$$

- (a) How many moles of N_2 are produced by the decomposition of 1.50 mol of NaN3?
- (b) How many grams of NaN₃ are required to form 10.0 g of nitrogen gas?
- (c) How many grams of NaN3 are required to produce 10.0 ft³ of nitrogen gas, about the size of an automotive air bag, if the gas has a density of 1.25 g/L?
- 3.68 The complete combustion of octane, C_8H_{18} , a component of gasoline, proceeds as follows:

$$2 C_8 H_{18}(l) + 25 O_2(g) \longrightarrow 16 CO_2(g) + 18 H_2 O(g)$$

- (a) How many moles of O₂ are needed to burn 1.50 mol of C₈H₁₈?
- **(b)** How many grams of O_2 are needed to burn 10.0 g of C_8H_{18} ?
- (c) Octane has a density of 0.692 g/mL at 20 °C. How many grams of O2 are required to burn 15.0 gal of C8H18 (the capacity of an average fuel tank)?
- (d) How many grams of CO₂ are produced when 15.0 gal of C₈H₁₈ are combusted?
- 3.69 A piece of aluminum foil $1.00\,\mathrm{cm}^2$ and $0.550\mathrm{-mm}$ thick is allowed to react with bromine to form aluminum bromide.

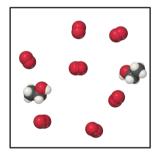

- (a) How many moles of aluminum were used? (The density of aluminum is 2.699 g/cm³.) (b) How many grams of aluminum bromide form, assuming the aluminum reacts completely?
- **3.70** Detonation of nitroglycerin proceeds as follows:

$$4 C_3 H_5 N_3 O_9(l) \longrightarrow 12 CO_2(g) + 6 N_2(g) + O_2(g) + 10 H_2 O(g)$$

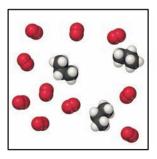

(a) If a sample containing 2.00 mL of nitroglycerin (density = 1.592 g/mL) is detonated, how many total moles of gas are produced? (b) If each mole of gas occupies 55 L under the conditions of the explosion, how many liters of gas are produced? (c) How many grams of N₂ are produced in the detonation?

Limiting Reactants (Section 3.7)

- **3.71** (a) Define the terms *limiting reactant* and *excess reactant*. (b) Why are the amounts of products formed in a reaction determined only by the amount of the limiting reactant? (c) Why should you base your choice of which compound is the limiting reactant on its number of initial moles, not on its initial mass in grams?
- **3.72** (a) Define the terms theoretical yield, actual yield, and percent *yield.* (b) Why is the actual yield in a reaction almost always less than the theoretical yield? (c) Can a reaction ever have 110% actual yield?
- 3.73 A manufacturer of bicycles has 4815 wheels, 2305 frames, and 2255 handlebars. (a) How many bicycles can be manufactured using these parts? (b) How many parts of each kind are left over? (c) Which part limits the production of bicycles?
- 3.74 A bottling plant has 126,515 bottles with a capacity of 355 mL, 108,500 caps, and 48,775 L of beverage. (a) How many bottles can be filled and capped? (b) How much of each item is left over? (c) Which component limits the production?
- 3.75 Consider the mixture of ethanol, C₂H₅OH, and O₂ shown in the accompanying diagram. (a) Write a balanced equation for the combustion reaction that occurs between ethanol and oxygen. (b) Which reactant is the limiting reactant? (c) How many molecules of CO₂, H₂O, C₂H₅OH, and O₂ will be present if the reaction goes to completion?

3.76 Consider the mixture of propane, C₃H₈, and O₂ shown below. (a) Write a balanced equation for the combustion reaction that occurs between propane and oxygen. (b) Which reactant is the limiting reactant? (c) How many molecules of CO₂, H₂O, C₃H₈, and O_2 will be present if the reaction goes to completion?

3.77 Sodium hydroxide reacts with carbon dioxide as follows:

$$2 \text{ NaOH}(s) + \text{CO}_2(g) \longrightarrow \text{Na}_2\text{CO}_3(s) + \text{H}_2\text{O}(l)$$

Which is the limiting reactant when 1.85 mol NaOH and 1.00 mol CO₂ are allowed to react? How many moles of Na₂CO₃ can be produced? How many moles of the excess reactant remain after the completion of the reaction?

3.78 Aluminum hydroxide reacts with sulfuric acid as follows:

$$2 \text{ Al}(OH)_3(s) + 3 \text{ H}_2SO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 6 \text{ H}_2O(l)$$

Which is the limiting reactant when 0.500 mol $Al(OH)_3$ and 0.500 mol H_2SO_4 are allowed to react? How many moles of $Al_2(SO_4)_3$ can form under these conditions? How many moles of the excess reactant remain after the completion of the reaction?

3.79 The fizz produced when an Alka-Seltzer tablet is dissolved in water is due to the reaction between sodium bicarbonate (NaHCO₃) and citric acid (H₃C₆H₅O₇):

$$3 \text{ NaHCO}_3(aq) + \text{H}_3\text{C}_6\text{H}_5\text{O}_7(aq) \longrightarrow 3 \text{CO}_2(g) + 3\text{H}_2\text{O}(l) + \text{Na}_3\text{C}_6\text{H}_5\text{O}_7(aq)$$

In a certain experiment 1.00 g of sodium bicarbonate and 1.00 g of citric acid are allowed to react. (a) Which is the limiting reactant? (b) How many grams of carbon dioxide form? (c) How many grams of the excess reactant remain after the limiting reactant is completely consumed?

3.80 One of the steps in the commercial process for converting ammonia to nitric acid is the conversion of NH₃ to NO:

$$4 \text{ NH}_3(g) + 5 \text{ O}_2(g) \longrightarrow 4 \text{ NO}(g) + 6 \text{ H}_2\text{O}(g)$$

In a certain experiment, 2.00 g of NH₃ reacts with 2.50 g of O₂. (a) Which is the limiting reactant? (b) How many grams of NO and H₂O form? (c) How many grams of the excess reactant remain after the limiting reactant is completely consumed? (d) Show that your calculations in

parts (b) and (c) are consistent with the law of conservation of mass.

- **3.81** Solutions of sodium carbonate and silver nitrate react to form solid silver carbonate and a solution of sodium nitrate. A solution containing 3.50 g of sodium carbonate is mixed with one containing 5.00 g of silver nitrate. How many grams of sodium carbonate, silver nitrate, silver carbonate, and sodium nitrate are present after the reaction is complete?
- 3.82 Solutions of sulfuric acid and lead(II) acetate react to form solid lead(II) sulfate and a solution of acetic acid. If 5.00 g of sulfuric acid and 5.00 g of lead(II) acetate are mixed, calculate the number of grams of sulfuric acid, lead(II) acetate, lead(II) sulfate, and acetic acid present in the mixture after the reaction is complete.
- 3.83 When benzene (C₆H₆) reacts with bromine (Br₂), bromobenzene (C₆H₅Br) is obtained:

$$C_6H_6 + Br_2 \longrightarrow C_6H_5Br + HBr$$

- (a) When 30.0 g of benzene reacts with 65.0 g of bromine, what is the theoretical yield of bromobenzene? (b) If the actual yield of bromobenzene is 42.3 g, what is the percentage yield?
- 3.84 When ethane (C₂H₆) reacts with chlorine (Cl₂), the main product is C₂H₅Cl, but other products containing Cl, such as C₂H₄Cl₂, are also obtained in small quantities. The formation of these other products reduces the yield of C₂H₅Cl. (a) Calculate the theoretical yield of C₂H₅Cl when 125 g of C₂H₆ reacts with 255 g of Cl₂, assuming that C₂H₆ and Cl₂ react only to form C₂H₂Cl and HCl. (b) Calculate the percent yield of C₂H₅Cl if the reaction produces 206 g of C₂H₅Cl.
- **3.85** Hydrogen sulfide is an impurity in natural gas that must be removed. One common removal method is called the Claus process, which relies on the reaction:

$$8 H_2S(g) + 4 O_2(g) \longrightarrow S_8(l) + 8 H_2O(g)$$

Under optimal conditions the Claus process gives 98% yield of S_8 from H_2S . If you started with 30.0 grams of H_2S and 50.0 grams of O_2 , how many grams of S_8 would be produced, assuming 98% yield?

3.86 When hydrogen sulfide gas is bubbled into a solution of sodium hydroxide, the reaction forms sodium sulfide and water. How many grams of sodium sulfide are formed if 1.25 g of hydrogen sulfide is bubbled into a solution containing 2.00 g of sodium hydroxide, assuming that the sodium sulfide is made in 92.0% yield?

Additional Exercises

- **3.87** Write the balanced chemical equations for (a) the complete combustion of acetic acid (CH₃COOH), the main active ingredient in vinegar; (b) the decomposition of solid calcium hydroxide into solid calcium (II) oxide (lime) and water vapor; (c) the combination reaction between nickel metal and chlorine gas.
- 3.88 If $1.5 \text{ mol } C_2H_5OH$, $1.5 \text{ mol } C_3H_8$, and $1.5 \text{ mol } CH_2COCH_3$ are completely combusted in oxygen, which produces the largest number of moles of H_2O ? Which produces the least? Explain.
- **3.89** The effectiveness of nitrogen fertilizers depends on both their ability to deliver nitrogen to plants and the amount of

nitrogen they can deliver. Four common nitrogen-containing fertilizers are ammonia, ammonium nitrate, ammonium sulfate, and urea $[(NH_2)_2CO]$. Rank these fertilizers in terms of the mass percentage nitrogen they contain.

- 3.90 (a) The molecular formula of acetylsalicylic acid (aspirin), one of the most common pain relievers, is C₉H₈O₄. How many moles of C₉H₈O₄ are in a 0.500-g tablet of aspirin?
 (b) How many molecules of C₉H₈O₄ are in this tablet?
 (c) How many carbon atoms are in the tablet?
- **3.91** Very small crystals composed of 1000 to 100,000 atoms, called quantum dots, are being investigated for use in electronic devices.
 - (a) A quantum dot was made of solid silicon in the shape of a sphere, with a diameter of 4 nm. Calculate the mass of the quantum dot, using the density of silicon (2.3 g/cm^3) .
 - (b) How many silicon atoms are in the quantum dot?
 - (c) The density of germanium is 5.325 g/cm³. If you made a 4-nm quantum dot of germanium, how many Ge atoms would it contain? Assume the dot is spherical.
- **3.92** (a) One molecule of the antibiotic penicillin G has a mass of 5.342×10^{-21} g. What is the molar mass of penicillin G?
 - **(b)** Hemoglobin, the oxygen-carrying protein in red blood cells, has four iron atoms per molecule and contains 0.340% iron by mass. Calculate the molar mass of hemoglobin.
- 3.93 Serotonin is a compound that conducts nerve impulses in the brain. It contains 68.2 mass percent C, 6.86 mass percent H, 15.9 mass percent N, and 9.08 mass percent O. Its molar mass is 176 g/mol. Determine its molecular formula.
- **3.94** The koala dines exclusively on eucalyptus leaves. Its digestive system detoxifies the eucalyptus oil, a poison to other animals. The chief constituent in eucalyptus oil is a substance called eucalyptol, which contains 77.87% C, 11.76% H, and the remainder O. (a) What is the empirical formula for this substance? (b) A mass spectrum of eucalyptol shows a peak at about 154 amu. What is the molecular formula of the substance?
- 3.95 Vanillin, the dominant flavoring in vanilla, contains C, H, and O. When 1.05 g of this substance is completely combusted, 2.43 g of CO₂ and 0.50 g of H₂O are produced. What is the empirical formula of vanillin?
- **3.96** An organic compound was found to contain only C, H, and Cl. When a 1.50-g sample of the compound was completely combusted in air, 3.52 g of $\rm CO_2$ was formed. In a separate experiment the chlorine in a 1.00-g sample of the compound was converted to 1.27 g of AgCl. Determine the empirical formula of the compound.
- **3.97** A compound, KBrO_x, where *x* is unknown, is analyzed and found to contain 52.92% Br. What is the value of *x*?
- **3.98** An element X forms an iodide (Xl_3) and a chloride (XCl_3) . The iodide is quantitatively converted to the chloride when it is heated in a stream of chlorine:

$$2 XI_3 + 3 Cl_2 \longrightarrow 2 XCl_3 + 3 I_2$$

If 0.5000 g of Xl_3 is treated, 0.2360 g of XCl_3 is obtained. (a) Calculate the atomic weight of the element X. (b) Identify the element X.

3.99 A method used by the U.S. Environmental Protection Agency (EPA) for determining the concentration of ozone in air is to pass the air sample through a "bubbler" containing sodium iodide, which removes the ozone according to the following equation:

$$O_3(g) + 2 \text{ NaI}(aq) + H_2O(l) \longrightarrow O_2(g) + I_2(s) + 2 \text{ NaOH}(aq)$$

- (a) How many moles of sodium iodide are needed to remove 5.95×10^{-6} mol of O_3 ? (b) How many grams of sodium iodide are needed to remove 1.3 mg of O_3 ?
- **3.100** A chemical plant uses electrical energy to decompose aqueous solutions of NaCl to give Cl₂, H₂, and NaOH:

$$2 \operatorname{NaCl}(aq) + 2 \operatorname{H}_2 \operatorname{O}(l) \longrightarrow 2 \operatorname{NaOH}(aq) + \operatorname{H}_2(g) + \operatorname{Cl}_2(g)$$

If the plant produces 1.5 \times 10⁶ kg (1500 metric tons) of Cl₂ daily, estimate the quantities of H₂ and NaOH produced.

- **3.101** The fat stored in a camel's hump is a source of both energy and water. Calculate the mass of H_2O produced by the metabolism of 1.0 kg of fat, assuming the fat consists entirely of tristearin $(C_{57}H_{110}O_6)$, a typical animal fat, and assuming that during metabolism, tristearin reacts with O_2 to form only CO_2 and H_2O .
- **3.102** When hydrocarbons are burned in a limited amount of air, both CO and CO₂ form. When 0.450 g of a particular hydrocarbon was burned in air, 0.467 g of CO, 0.733 g of CO₂, and 0.450 g of H₂O were formed. (a) What is the empirical formula of the compound? (b) How many grams of O₂ were used in the reaction? (c) How many grams would have been required for complete combustion?
- **3.103** A mixture of $N_2(g)$ and $H_2(g)$ reacts in a closed container to form ammonia, $NH_3(g)$. The reaction ceases before either reactant has been totally consumed. At this stage 3.0 mol N_2 , 3.0 mol H_2 , and 3.0 mol NH_3 are present. How many moles of N_2 and H_2 were present originally?
- **3.104** A mixture containing KClO₃, K₂CO₃, KHCO₃, and KCl was heated, producing CO₂, O₂, and H₂O gases according to the following equations:

$$2 \text{ KClO}_3(s) \longrightarrow 2 \text{ KCl}(s) + 3 \text{ O}_2(g)$$

$$2 \text{ KHCO}_3(s) \longrightarrow \text{K}_2\text{O}(s) + \text{H}_2\text{O}(g) + 2 \text{ CO}_2(g)$$

$$\text{K}_2\text{CO}_3(s) \longrightarrow \text{K}_2\text{O}(s) + \text{CO}_2(g)$$

The KCl does not react under the conditions of the reaction. If 100.0 g of the mixture produces 1.80 g of H_2O , 13.20 g of CO_2 , and 4.00 g of O_2 , what was the composition of the original mixture? (Assume complete decomposition of the mixture.)

3.105 When a mixture of 10.0 g of acetylene (C₂H₂) and 10.0 g of oxygen (O₂) is ignited, the resultant combustion reaction produces CO₂ and H₂O. (a) Write the balanced chemical equation for this reaction. (b) Which is the limiting reactant? (c) How many grams of C₂H₂, O₂, CO₂, and H₂O are present after the reaction is complete?

Integrative Exercises

These exercises require skills from earlier chapters as well as skills from the present chapter.

- 3.106 Consider a sample of calcium carbonate in the form of a cube measuring 2.005 in. on each edge. If the sample has a density of 2.71 g/cm³, how many oxygen atoms does it contain?
- **3.107** (a) You are given a cube of silver metal that measures 1.000 cm on each edge. The density of silver is $10.5 \,\mathrm{g/cm^3}$. How many atoms are in this cube? (b) Because atoms are spherical, they cannot occupy all of the space of the cube. The silver atoms pack in the solid in such a way that 74% of the volume of the solid is actually filled with the silver atoms. Calculate the volume of a single silver atom. (c) Using the volume of a silver atom and the formula for the volume of a sphere, calculate the radius in angstroms of a silver atom.
- **3.108** (a) If an automobile travels 225 mi with a gas mileage of 20.5 mi/gal, how many kilograms of CO_2 are produced? Assume that the gasoline is composed of octane, $C_8H_{18}(l)$, whose density is 0.69 g/mL. (b) Repeat the calculation for a truck that has a gas mileage of 5 mi/gal.
- 3.109 Section 2.9 introduced the idea of structural isomerism, with 1-propanol and 2-propanol as examples. Determine which of these properties would distinguish these two substances:
 (a) boiling point, (b) combustion analysis results, (c) molecular weight, (d) density at a given temperature and pressure. You can check on the properties of these two compounds in Wolfram Alpha (http://www.wolframalpha.com/) or the CRC Handbook of Chemistry and Physics.
- 3.110 A particular coal contains 2.5% sulfur by mass. When this coal is burned at a power plant, the sulfur is converted into sulfur dioxide gas, which is a pollutant. To reduce sulfur dioxide emissions, calcium oxide (lime) is used. The sulfur dioxide reacts with calcium oxide to form solid calcium sulfite.

 (a) Write the balanced chemical equation for the reaction.
 (b) If the coal is burned in a power plant that uses 2000 tons of coal per day, what mass of calcium oxide is required daily to eliminate the sulfur dioxide? (c) How many grams of calcium sulfite are produced daily by this power plant?

3.111 Hydrogen cyanide, HCN, is a poisonous gas. The lethal dose is approximately 300 mg HCN per kilogram of air when inhaled. (a) Calculate the amount of HCN that gives the lethal dose in a small laboratory room measuring $12 \times 15 \times 8.0$ ft. The density of air at 26 °C is $0.00118 \, \text{g/cm}^3$. (b) If the HCN is formed by reaction of NaCN with an acid such as H_2SO_4 , what mass of NaCN gives the lethal dose in the room?

$$2 \text{ NaCN}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{Na}_2\text{SO}_4(aq) + 2 \text{ HCN}(g)$$

- (c) HCN forms when synthetic fibers containing Orlon® or Acrilan® burn. Acrilan® has an empirical formula of CH₂CHCN, so HCN is 50.9% of the formula by mass. A rug measures 12×15 ft and contains 30 oz of Acrilan® fibers per square yard of carpet. If the rug burns, will a lethal dose of HCN be generated in the room? Assume that the yield of HCN from the fibers is 20% and that the carpet is 50% consumed.
- 3.112 The source of oxygen that drives the internal combustion engine in an automobile is air. Air is a mixture of gases, principally $N_2(\sim 79\%)$ and $O_2(\sim 20\%)$. In the cylinder of an automobile engine, nitrogen can react with oxygen to produce nitric oxide gas, NO. As NO is emitted from the tailpipe of the car, it can react with more oxygen to produce nitrogen dioxide gas. (a) Write balanced chemical equations for both reactions. (b) Both nitric oxide and nitrogen dioxide are pollutants that can lead to acid rain and global warming; collectively, they are called "NO_x" gases. In 2007, the United States emitted an estimated 22 million tons of nitrogen dioxide into the atmosphere. How many grams of nitrogen dioxide is this? (c) The production of NO_r gases is an unwanted side reaction of the main engine combustion process that turns octane, C₈H₁₈, into CO₂ and water. If 85% of the oxygen in an engine is used to combust octane and the remainder used to produce nitrogen dioxide, calculate how many grams of nitrogen dioxide would be produced during the combustion of 500 g of

Design an Experiment

You will learn later in this book that sulfur is capable of forming two common oxides, SO_2 and SO_3 . One question that we might ask is whether the direct reaction between sulfur and oxygen leads to the formation of SO_2 , SO_3 , or a mixture of the two. This question has practical significance because SO_3 can go onto react with water to form sulfuric acid, H_2SO_4 , which is produced industrially on a very large scale. Consider also that the answer to this question may depend on the relative amount of each element that is present and the temperature at which the reaction is carried out. For example, carbon and oxygen normally react to form CO_2 but, when there is not enough oxygen present, CO can form. On the other hand, under normal reaction conditions H_2 and O_2 react to form water, H_2O (rather than hydrogen peroxide H_2O_2) regardless of the starting ratio of hydrogen to oxygen.

Suppose you are given a bottle of sulfur, which is a yellow solid, a cylinder of O_2 , a transparent reaction vessel that can be evacuated and sealed so that only sulfur, oxygen and the product(s) of the reaction between the two are present, an analytical balance so that you can determine the masses of the reactants and/or products, and a furnace that can be used to heat the reaction vessel to 200 °C where the two elements react. (a) If you start with 0.10 mol of sulfur in the reaction

vessel how many moles of oxygen would need to be added to form SO_2 , assuming SO_2 forms exclusively? (b) How many moles of oxygen would be needed to form SO_3 , assuming SO_3 forms exclusively? (c) Given the available equipment how would you determine if you added the correct number of moles of each reactant to the reaction vessel? (d) What observation or experimental technique would you use to determine the identity of the reaction product(s)? Could differences in the physical properties of SO_2 and SO_3 be used to help identify the product(s)? Have any instruments been described Chapters 1–3 that would allow you to identify the product(s)? (e) What experiments would you conduct to determine if the product(s) of this reaction (either SO_2 or SO_3 or a mixture of the two) can be controlled by varying the ratio of sulfur and oxygen that are added to the reaction vessel? What ratio(s) of S to O_2 would you test to answer this question?

Reactions in Aqueous Solution

Water covers nearly two-thirds of our planet, and this simple substance has been the key to much of Earth's evolutionary history. Life almost certainly originated in water, and the need for water by all forms of life has helped determine diverse biological structures.

Scientists had studied the chemistry of the ocean for decades before discovering deep sea vents in 1979. The chemical reactions that occur near deep sea vents are, as you might imagine, difficult to study; nonetheless, chemists working in deep-sea submersibles equipped with sampling arms are helping us learn what happens in these hot, toxic waters.

One reaction that occurs in deep sea vents is the conversion of FeS into FeS₂:

$$FeS(s) + H_2S(g) \longrightarrow FeS_2(s) + H_2(g)$$
 [4.1]

If we could follow the iron atoms in this reaction as it proceeds, we would learn that they gain and lose electrons and are dissolved in water to different extents at different times (Figure 4.1).

A solution in which water is the dissolving medium is called an **aqueous solution**. In this chapter we examine chemical reactions that take place in aqueous solutions. In addition, we extend the concepts of stoichiometry learned in Chapter 3 by considering how solution concentrations are expressed and used. Although the reactions we will discuss in this chapter are relatively simple, they form the basis for understanding very complex reaction cycles in biology, geology, and oceanography.

▶ DEEP SEA VENTS are amazing places. Superheated water (up to 400 °C) is released from cracks in the bottom of the ocean. Rocks dissolve and reform. The locally high mineral content and sulfur-containing substances in the water provide an environment that favors unusual organisms that are found nowhere else in the world.

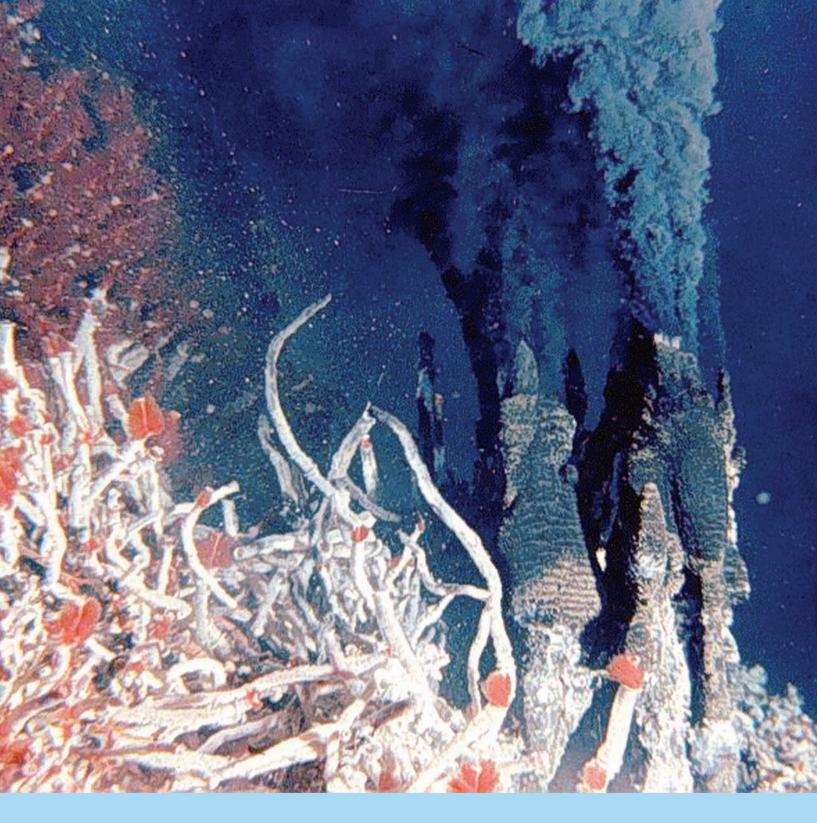

4.1 GENERAL PROPERTIES OF AQUEOUS SOLUTIONS We begin by examining whether substances dissolved in water exist as ions, molecules, or a mixture of the two.

4.2 PRECIPITATION REACTIONS We identify reactions in which soluble reactants yield an insoluble product.

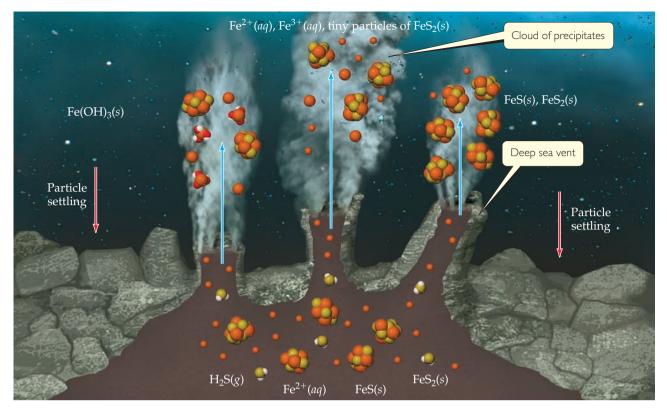

4.3 ACIDS, BASES, AND NEUTRALIZATION REACTIONS We explore reactions in which protons, H⁺ ions, are transferred from one reactant to another.

4.4 OXIDATION-REDUCTION REACTIONS We examine reactions in which electrons are transferred from one reactant to another.

4.5 CONCENTRATIONS OF SOLUTIONS We learn how the amount of a compound dissolved in a given volume of a solution can be expressed as a *concentration*. Concentration can be defined in many ways; the most common way in chemistry is moles of compound per liter of solution (*molarity*).

4.6 SOLUTION STOICHIOMETRY AND CHEMICAL ANALYSIS We see how the concepts of stoichiometry and concentration can be used to calculate amounts or concentrations of substances in solution through a common chemical practice called *titration*.

▲ Figure 4.1 Researchers have recently found that compounds containing iron, sulfur, and oxygen are the reactants and products in a deep sea vent.

4.1 | General Properties of Aqueous Solutions

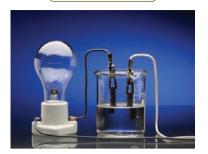

A *solution* is a homogeneous mixture of two or more substances. (Section 1.2) The substance present in the greatest quantity is usually called the **solvent**, and the other substances are called **solutes**; they are said to be *dissolved in* the solvent. When a small amount of sodium chloride (NaCl) is dissolved in a large quantity of water, for example, water is the solvent and sodium chloride is the solute.

Electrolytes and Nonelectrolytes

At a young age we learn not to bring electrical devices into the bathtub so as not to electrocute ourselves. That is a useful lesson because most of the water we encounter in daily life is electrically conducting. Pure water, however, is a very poor conductor of electricity. The conductivity of bathwater originates from the substances dissolved in the water, not from the water itself.

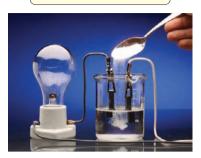

Not all substances that dissolve in water make the resulting solution conducting. Experiments show that some solutions conduct electricity better than others. Imagine, for example, preparing two aqueous solutions—one by dissolving a teaspoon of table salt (sodium chloride) in a cup of water and the other by dissolving a teaspoon of table sugar (sucrose) in a cup of water (>> Figure 4.2). Both solutions are clear and colorless, but they possess very different electrical conductivities: The salt solution is a good conductor of electricity, which we can see from the light bulb turning on. In order for the light bulb in Figure 4.2 to turn on, there must be an electric current (that is, a *flow* of electrically charged particles) between the two electrodes immersed in the solution. The conductivity of pure water is not sufficient to complete the electrical circuit and light

Pure water does not conduct electricity

Pure water, $H_2O(l)$

An **nonelectrolyte solution** does not conduct electricity

Sucrose solution, $C_{12}H_{22}O_{11}(aq)$

An **electrolyte solution** conducts electricity

Sodium chloride solution, NaCl(aq)

▲ Figure 4.2 Completion of an electrical circuit with an electrolyte turns on the light.

the bulb. The situation would change if ions were present in solution, because the ions carry electrical charge from one electrode to the other, completing the circuit. Thus, the conductivity of NaCl solutions indicates the presence of ions. The lack of conductivity of sucrose solutions indicates the absence of ions. When NaCl dissolves in water, the solution contains Na^+ and Cl^- ions, each surrounded by water molecules. When sucrose $(C_{12}H_{22}O_{11})$ dissolves in water, the solution contains only neutral sucrose molecules surrounded by water molecules.

A substance (such as NaCl) whose aqueous solutions contain ions is called an **electrolyte**. A substance (such as $C_{12}H_{22}O_{11}$) that does not form ions in solution is called a **nonelectrolyte**. The different classifications of NaCl and $C_{12}H_{22}O_{11}$ arise largely because NaCl is an ionic compound, whereas $C_{12}H_{22}O_{11}$ is a molecular compound.

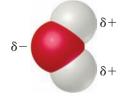

How Compounds Dissolve in Water

Recall from Figure 2.19 that solid NaCl consists of an orderly arrangement of Na⁺ and Cl⁻ ions. When NaCl dissolves in water, each ion separates from the solid structure and disperses throughout the solution [Figure 4.3(a)]. The ionic solid *dissociates* into its component ions as it dissolves.

Water is a very effective solvent for ionic compounds. Although H_2O is an electrically neutral molecule, the O atom is rich in electrons and has a partial negative charge, while each H atom has a partial positive charge. The lowercase Greek letter delta (δ) is used to denote partial charge: A partial negative charge is denoted δ^- ("delta minus"), and a partial positive charge is denoted by δ^+ ("delta plus"). Cations are attracted by the negative end of H_2O , and anions are attracted by the positive end.

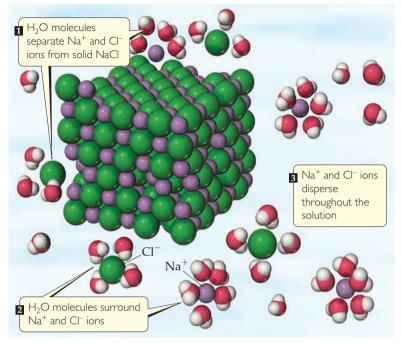

As an ionic compound dissolves, the ions become surrounded by H_2O molecules, as shown in Figure 4.3(a). The ions are said to be *solvated*. In chemical equations, we denote solvated ions by writing them as $Na^+(aq)$ and $Cl^-(aq)$, where aq is an abbreviation for "aqueous." ∞ (Section 3.1) **Solvation** helps stabilize the ions in solution and prevents cations and anions from recombining. Furthermore, because the ions and their shells of surrounding water molecules are free to move about, the ions become dispersed uniformly throughout the solution.

We can usually predict the nature of the ions in a solution of an ionic compound from the chemical name of the substance. Sodium sulfate (Na_2SO_4), for example, dissociates into sodium ions (Na^+) and sulfate ions ($SO_4^{\,2^-}$). You must remember the formulas and charges of common ions (Tables 2.4 and 2.5) to understand the forms in which ionic compounds exist in aqueous solution.

GO FIGURE

Which solution, NaCl(aq) or CH₃OH(aq), conducts electricity?

Methanol

(a) Ionic compounds like sodium chloride, NaCl, form ions when they dissolve.

(b) Molecular substances like methanol, CH₃OH, dissolve without forming ions.

▲ Figure 4.3 Dissolution in water. (a) When an ionic compound, such as sodium chloride, NaCl, dissolves in water, H₂O molecules separate, surround, and uniformly disperse the ions into the liquid. (b) Molecular substances that dissolve in water, such as methanol, CH₃OH, usually do so without forming ions. We can think of methanol in water as a simple mixing of two molecular species. In both (a) and (b) the water molecules have been moved apart so that the solute particles can be seen clearly.

Give It Some Thought

What dissolved species are present in a solution of

- (a) KCN?
- (b) $NaCIO_4$?

When a molecular compound such as sucrose or methanol [Figure 4.3(b)] dissolves in water, the solution usually consists of intact molecules dispersed throughout the solution. Consequently, most molecular compounds are nonelectrolytes. A few molecular substances do have aqueous solutions that contain ions. Acids are the most important of these solutions. For example, when HCl(g) dissolves in water to form hydrochloric acid, HCl(aq), the molecule *ionizes*; that is, it dissociates into $H^+(aq)$ and $Cl^-(aq)$ ions.

Strong and Weak Electrolytes

Electrolytes differ in the extent to which they conduct electricity. **Strong electrolytes** are those solutes that exist in solution completely or nearly completely as ions. Essentially all water-soluble ionic compounds (such as NaCl) and a few molecular compounds (such as HCl) are strong electrolytes. Weak electrolytes are those solutes that exist in solution mostly in the form of neutral molecules with only a small fraction in the form of ions. For example, in a solution of acetic acid (CH₃COOH), most of the

solute is present as $CH_3COOH(aq)$ molecules. Only a small fraction (about 1%) of the CH_3COOH has dissociated into $H^+(aq)$ and $CH_3COO^-(aq)$ ions.*

We must be careful not to confuse the extent to which an electrolyte dissolves (its solubility) with whether it is strong or weak. For example, CH_3COOH is extremely soluble in water but is a weak electrolyte. $Ca(OH)_2$, on the other hand, is not very soluble in water, but the amount that does dissolve dissociates almost completely. Thus, $Ca(OH)_2$ is a strong electrolyte.

When a weak electrolyte, such as acetic acid, ionizes in solution, we write the reaction in the form

$$CH_3COOH(aq) \rightleftharpoons CH_3COO^-(aq) + H^+(aq)$$
 [4.2]

The half-arrows pointing in opposite directions mean that the reaction is significant in both directions. At any given moment some CH_3COOH molecules are ionizing to form H^+ and CH_3COO^- ions but H^+ and CH_3COO^- ions are recombining to form CH_3COOH . The balance between these opposing processes determines the relative numbers of ions and neutral molecules. This balance produces a state of **chemical equilibrium** in which the relative numbers of each type of ion or molecule in the reaction are constant over time. Chemists use half-arrows pointing in opposite directions to represent reactions that go both forward and backward to achieve equilibrium, such as the ionization of weak electrolytes. In contrast, a single reaction arrow is used for reactions that largely go forward, such as the ionization of strong electrolytes. Because HCl is a strong electrolyte, we write the equation for the ionization of HCl as

$$HCl(aq) \longrightarrow H^{+}(aq) + Cl^{-}(aq)$$
 [4.3]

The absence of a left-pointing half-arrow indicates that the H⁺ and Cl⁻ ions have no tendency to recombine to form HCl molecules.

In the following sections we will look at how a compound's composition lets us predict whether it is a strong electrolyte, weak electrolyte, or nonelectrolyte. For the moment, you need only to remember that *water-soluble ionic compounds are strong electrolytes*. Ionic compounds can usually be identified by the presence of both metals and nonmetals [for example, NaCl, FeSO₄, and Al(NO₃)₃]. Ionic compounds containing the ammonium ion, NH₄ $^+$ [for example, NH₄Br and (NH₄)₂CO₃], are exceptions to this rule of thumb.

Give It Some Thought

Which solute will cause the light bulb in Figure 4.2 to glow most brightly, CH_3OH , NaOH, or CH_3COOH ?

SAMPLE EXERCISE 4.1

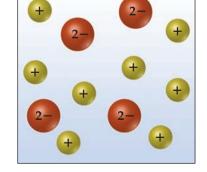

Relating Relative Numbers of Anions and Cations to Chemical Formulas

The accompanying diagram represents an aqueous solution of either MgCl₂, KCl, or K₂SO₄. Which solution does the drawing best represent?

SOLUTION

Analyze We are asked to associate the charged spheres in the diagram with ions present in a solution of an ionic substance.

Plan We examine each ionic substance given to determine the relative numbers and charges of its ions. We then correlate these ionic species with the ones shown in the diagram.

^{*}The chemical formula of acetic acid is sometimes written $HC_2H_3O_2$ so that the formula looks like that of other common acids such as HCl. The formula CH_3COOH conforms to the molecular structure of acetic acid, with the acidic H on the O atom at the end of the formula.

Solve The diagram shows twice as many cations as anions, consistent with the formulation K_2SO_4 .

Check Notice that the net charge in the diagram is zero, as it must be if it is to represent an ionic substance.

Practice Exercise 1

If you have an aqueous solution that contains 1.5 moles of HCl, how many moles of ions are in the solution? (a) 1.0, (b) 1.5, (c) 2.0, (d) 2.5, (e) 3.0

Practice Exercise 2

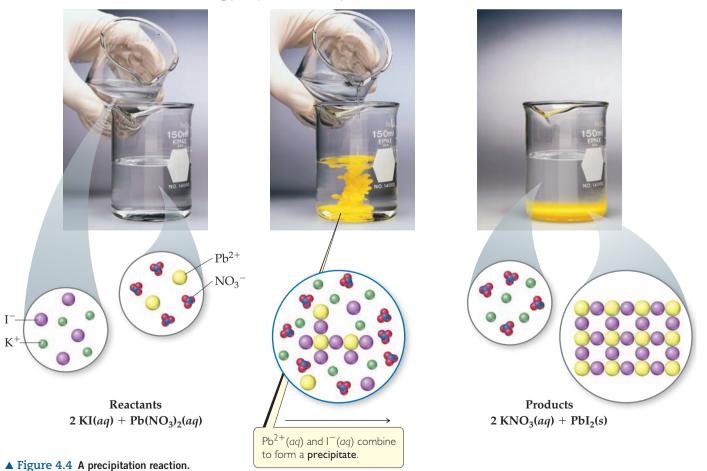

If you were to draw diagrams representing aqueous solutions of (a) $NiSO_4$, (b) $Ca(NO_3)_2$, (c) Na_3PO_4 , (d) $Al_2(SO_4)_3$, how many anions would you show if each diagram contained six cations?

4.2 | Precipitation Reactions

▼ Figure 4.4 shows two clear solutions being mixed. One solution contains potassium iodide, KI, dissolved in water and the other contains lead nitrate, Pb(NO₃)₂, dissolved in water. The reaction between these two solutes produces a water-insoluble yellow solid. Reactions that result in the formation of an insoluble product are called **precipitation reactions**. A **precipitate** is an insoluble solid formed by a reaction in solution.

Which ions remain in solution after PbI₂ precipitation is complete?

In Figure 4.4 the precipitate is lead iodide (PbI₂), a compound that has a very low solubility in water:

$$Pb(NO_3)_2(aq) + 2 KI(aq) \longrightarrow PbI_2(s) + 2 KNO_3(aq)$$
 [4.4]

The other product of this reaction, potassium nitrate (KNO₃), remains in solution.

Precipitation reactions occur when pairs of oppositely charged ions attract each other so strongly that they form an insoluble ionic solid. These reactions are very common in the ocean, including the deep sea vents we discussed earlier. To predict whether certain combinations of ions form insoluble compounds, we must consider some guidelines concerning the solubilities of common ionic compounds.

Solubility Guidelines for Ionic Compounds

The **solubility** of a substance at a given temperature is the amount of the substance that can be dissolved in a given quantity of solvent at the given temperature. In our discussions, any substance with a solubility less than 0.01 mol/L will be considered *insoluble*. In these cases the attraction between the oppositely charged ions in the solid is too great for the water molecules to separate the ions to any significant extent; the substance remains largely undissolved.

Unfortunately, there are no rules based on simple physical properties such as ionic charge to guide us in predicting whether a particular ionic compound will be soluble. Experimental observations, however, have led to guidelines for predicting solubility for ionic compounds. For example, experiments show that all common ionic compounds that contain the nitrate anion, NO_3^- , are soluble in water. \blacktriangledown Table 4.1 summarizes the solubility guidelines for common ionic compounds. The table is organized according to the anion in the compound, but it also reveals many important facts about cations. Note that all common ionic compounds of the alkali metal ions (group 1A of the periodic table) and of the ammonium ion (NH_4^+) are soluble in water.

To predict whether a precipitate forms when we mix aqueous solutions of two strong electrolytes, we must (1) note the ions present in the reactants, (2) consider the possible cation–anion combinations, and (3) use Table 4.1 to determine if any of these combinations is insoluble. For example, will a precipitate form when solutions of $Mg(NO_3)_2$ and NaOH are mixed? Both substances are soluble ionic compounds and strong electrolytes. Mixing the solutions first produces a solution containing

Table 4.1 Solubility Guidelines for Common Ionic Compounds in Water				
Soluble Ionic Compounds		Important Exceptions		
Compounds containing	NO ₃	None		
	CH ₃ COO ⁻	None		
	CI ⁻	Compounds of Ag ⁺ , Hg ₂ ²⁺ , and Pb ²⁺		
	Br ⁻	Compounds of Ag ⁺ , Hg ₂ ²⁺ , and Pb ²⁺		
	Ι_	Compounds of Ag ⁺ , Hg ₂ ²⁺ , and Pb ²⁺		
	$\mathrm{SO_4}^{2-}$	Compounds of Sr ²⁺ , Ba ²⁺ , Hg ₂ ²⁺ , and Pb ²⁺		
Insoluble Ionic Compounds		Important Exceptions		
Compounds containing	S ²⁻	Compounds of NH ₄ ⁺ , the alkali metal cations, Ca ²⁺ , Sr ²⁺ , and Ba ²⁺		
	CO ₃ ²⁻	Compounds of $\mathrm{NH_4}^+$ and the alkali metal cations		
	PO ₄ ³⁻	Compounds of $\mathrm{NH_4}^+$ and the alkali metal cations		
	OH ⁻	Compounds of $\mathrm{NH_4}^+$, the alkali metal cations, $\mathrm{Ca^{2+}}$, $\mathrm{Sr^{2+}}$, and $\mathrm{Ba^{2+}}$		

 ${\rm Mg^{2^+}, NO_3^-, Na^+}$, and ${\rm OH^-}$ ions. Will either cation interact with either anion to form an insoluble compound? Knowing from Table 4.1 that ${\rm Mg(NO_3)_2}$ and NaOH are both soluble in water, our only possibilities are ${\rm Mg^{2^+}}$ with ${\rm OH^-}$ and ${\rm Na^+}$ with ${\rm NO_3^-}$. From Table 4.1 we see that hydroxides are generally insoluble. Because ${\rm Mg^{2^+}}$ is not an exception, ${\rm Mg(OH)_2}$ is insoluble and thus forms a precipitate. NaNO₃, however, is soluble, so ${\rm Na^+}$ and ${\rm NO_3^-}$ remain in solution. The balanced equation for the precipitation reaction is

$$Mg(NO_3)_2(aq) + 2 NaOH(aq) \longrightarrow Mg(OH)_2(s) + 2 NaNO_3(aq)$$
 [4.5]

SAMPLE EXERCISE 4.2 Using Solubility Rules

Classify these ionic compounds as soluble or insoluble in water: (a) sodium carbonate, Na_2CO_3 , (b) lead sulfate, $PbSO_4$.

SOLUTION

Analyze We are given the names and formulas of two ionic compounds and asked to predict whether they are soluble or insoluble in water.

 $\begin{tabular}{ll} \begin{tabular}{ll} \be$

Solve

- (a) According to Table 4.1, most carbonates are insoluble. But carbonates of the alkali metal cations (such as sodium ion) are an exception to this rule and are soluble. Thus, Na₂CO₃ is soluble in water.
- (b) Table 4.1 indicates that although most sulfates are water soluble, the sulfate of ${\rm Pb^{2+}}$ is an exception. Thus, ${\rm PbSO_4}$ is insoluble in water.

Practice Exercise 1

Which of the following compounds is insoluble in water? (a) (NH₄)₂S, (b) CaCO₃, (c) NaOH, (d) Ag₂SO₄, (e) Pb(CH₃COO)₂.

Practice Exercise 2

Classify the following compounds as soluble or insoluble in water: (a) cobalt(II) hydroxide, (b) barium nitrate, (c) ammonium phosphate.

Exchange (Metathesis) Reactions

Notice in Equation 4.5 that the reactant cations exchange anions— Mg^{2^+} ends up with OH⁻, and Na⁺ ends up with NO₃⁻. The chemical formulas of the products are based on the charges of the ions—two OH⁻ ions are needed to give a neutral compound with Mg^{2^+} , and one NO₃⁻ ion is needed to give a neutral compound with Na⁺. ∞ (Section 2.7) The equation can be balanced only after the chemical formulas of the products have been determined.

Reactions in which cations and anions appear to exchange partners conform to the general equation

Such reactions are called either **exchange reactions** or **metathesis reactions** (meh-TATH-eh-sis, Greek for "to transpose"). Precipitation reactions conform to this pattern, as do many neutralization reactions between acids and bases, as we will see in Section 4.3.

To complete and balance the equation for a metathesis reaction, we follow these steps:

- 1. Use the chemical formulas of the reactants to determine which ions are present.
- 2. Write the chemical formulas of the products by combining the cation from one reactant with the anion of the other, using the ionic charges to determine the subscripts in the chemical formulas.
- **3.** Check the water solubilities of the products. For a precipitation reaction to occur, at least one product must be insoluble in water.
- **4.** Balance the equation.

SAMPLE EXERCISE 4.3

Predicting a Metathesis Reaction

(a) Predict the identity of the precipitate that forms when aqueous solutions of $BaCl_2$ and K_2SO_4 are mixed. (b) Write the balanced chemical equation for the reaction.

SOLUTION

Analyze We are given two ionic reactants and asked to predict the insoluble product that they form.

Plan We need to write the ions present in the reactants and exchange the anions between the two cations. Once we have written the chemical formulas for these products, we can use Table 4.1 to determine which is insoluble in water. Knowing the products also allows us to write the equation for the reaction.

Solve

(a) The reactants contain Ba^{2+} , Cl^- , K^+ , and $SO_4^{\ 2-}$ ions. Exchanging the anions gives us $BaSO_4$ and KCl. According to Table 4.1, most compounds of $SO_4^{\ 2-}$ are soluble but those of Ba^{2+} are not. Thus, $BaSO_4$ is insoluble and will precipitate from solution. KCl is soluble.

(b) From part (a) we know the chemical formulas of the products, ${\rm BaSO_4}$ and KCl. The balanced equation is

$$BaCl_2(aq) + K_2SO_4(aq) \longrightarrow BaSO_4(s) + 2 KCl(aq)$$

Practice Exercise 1

Yes or No: Will a precipitate form when solutions of $Ba(NO_3)_2$ and KOH are mixed?

Practice Exercise 2

(a) What compound precipitates when aqueous solutions of Fe₂(SO₄)₃ and LiOH are mixed? (b) Write a balanced equation for the reaction.

Ionic Equations and Spectator Ions

In writing equations for reactions in aqueous solution, it is often useful to indicate whether the dissolved substances are present predominantly as ions or as molecules. Let's reconsider the precipitation reaction between $Pb(NO_3)_2$ and 2 KI (Eq. 4.4):

$$Pb(NO_3)_2(aq) + 2 KI(aq) \longrightarrow PbI_2(s) + 2 KNO_3(aq)$$

An equation written in this fashion, showing the complete chemical formulas of reactants and products, is called a **molecular equation** because it shows chemical formulas without indicating ionic character. Because Pb(NO₃)₂, KI, and KNO₃ are all water-soluble ionic compounds and therefore strong electrolytes, we can write the equation in a form that indicates which species exist as ions in the solution:

$$Pb^{2+}(aq) + 2 NO_3^{-}(aq) + 2 K^{+}(aq) + 2 \Gamma(aq) \longrightarrow$$

 $PbI_2(s) + 2 K^{+}(aq) + 2 NO_3^{-}(aq)$ [4.7]

An equation written in this form, with all soluble strong electrolytes shown as ions, is called a **complete ionic equation**.

Notice that $K^+(aq)$ and $NO_3^-(aq)$ appear on both sides of Equation 4.7. Ions that appear in identical forms on both sides of a complete ionic equation, called **spectator ions**, play no direct role in the reaction. When spectator ions are omitted from the equation (they cancel out like algebraic quantities), we are left with the **net ionic equation**, which is one that includes only the ions and molecules directly involved in the reaction:

$$Pb^{2+}(aq) + 2I^{-}(aq) \longrightarrow PbI_{2}(s)$$
 [4.8]

Because charge is conserved in reactions, the sum of the ionic charges must be the same on both sides of a balanced net ionic equation. In this case the 2+ charge of the cation and the two 1- charges of the anions add to zero, the charge of the electrically neutral product. *If every ion in a complete ionic equation is a spectator, no reaction occurs*.

Give It Some Thought

Which ions, if any, are spectator ions in this reaction?

$$AgNO_3(aq) + NaCl(aq) \longrightarrow AgCl(s) + NaNO_3(aq)$$

Net ionic equations illustrate the similarities between various reactions involving electrolytes. For example, Equation 4.8 expresses the essential feature of the

precipitation reaction between any strong electrolyte containing $Pb^{2+}(aq)$ and any strong electrolyte containing $\Gamma(aq)$: The ions combine to form a precipitate of PbI_2 . Thus, a net ionic equation demonstrates that more than one set of reactants can lead to the same net reaction. For example, aqueous solutions of KI and MgI_2 share many chemical similarities because both contain Γ ions. Either solution when mixed with a $Pb(NO_3)_2$ solution produces $PbI_2(s)$. The complete ionic equation, on the other hand, identifies the actual reactants that participate in a reaction.

The following steps summarize the procedure for writing net ionic equations:

- 1. Write a balanced molecular equation for the reaction.
- **2.** Rewrite the equation to show the ions that form in solution when each soluble strong electrolyte dissociates into its ions. *Only strong electrolytes dissolved in aqueous solution are written in ionic form.*
- 3. Identify and cancel spectator ions.

SAMPLE EXERCISE 4.4

Writing a Net Ionic Equation

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of calcium chloride and sodium carbonate are mixed.

SOLUTION

Analyze Our task is to write a net ionic equation for a precipitation reaction, given the names of the reactants present in solution.

Plan We write the chemical formulas of the reactants and products and then determine which product is insoluble. We then write and balance the molecular equation. Next, we write each soluble strong electrolyte as separated ions to obtain the complete ionic equation. Finally, we eliminate the spectator ions to obtain the net ionic equation.

Solve Calcium chloride is composed of calcium ions, Ca^{2+} , and chloride ions, Cl^- ; hence, an aqueous solution of the substance is $\operatorname{CaCl}_2(aq)$. Sodium carbonate is composed of Na^+ ions and $\operatorname{CO_3}^{2-}$ ions; hence, an aqueous solution of the compound is $\operatorname{Na}_2\operatorname{CO}_3(aq)$. In the molecular equations for precipitation reactions, the anions and cations appear to exchange partners. Thus, we put Ca^{2+} and $\operatorname{CO_3}^{2-}$ together to give $\operatorname{CaCO_3}$ and Na^+ and Cl^- together to give NaCl . According to the solubility guidelines in Table 4.1, $\operatorname{CaCO_3}$ is insoluble and NaCl is soluble. The balanced molecular equation is

$$CaCl_2(aq) + Na_2CO_3(aq) \longrightarrow CaCO_3(s) + 2 NaCl(aq)$$

In a complete ionic equation, *only* dissolved strong electrolytes (such as soluble ionic compounds) are written as separate ions. As the (aq) designations remind us, $CaCl_2$, Na_2CO_3 , and NaCl are all dissolved in the solution. Furthermore, they are all strong electrolytes. $CaCO_3$ is an ionic compound, but it is not soluble. We do not write the formula of any insoluble compound as its component ions. Thus, the complete ionic equation is

$$Ca^{2+}(aq) + 2 Cl^{-}(aq) + 2 Na^{+}(aq) + CO_{3}^{2-}(aq) \longrightarrow$$

 $CaCO_{3}(s) + 2 Na^{+}(aq) + 2 Cl^{-}(aq)$

The spectator ions are Na⁺ and Cl⁻. Canceling them gives the following net ionic equation:

$$Ca^{2+}(aq) + CO_3^{2-}(aq) \longrightarrow CaCO_3(s)$$

Check We can check our result by confirming that both the elements and the electric charge are balanced. Each side has one Ca, one C, and three O, and the net charge on each side equals 0.

Comment If none of the ions in an ionic equation is removed from solution or changed in some way, all ions are spectator ions and a reaction does not occur.

Practice Exercise 1

What happens when you mix an aqueous solution of sodium nitrate with an aqueous solution of barium chloride?
(a) There is no reaction; all possible products are soluble.
(b) Only barium nitrate precipitates. (c) Only sodium chloride precipitates. (d) Both barium nitrate and sodium chloride precipitate. (e) Nothing; barium chloride is not soluble and it stays as a precipitate.

Practice Exercise 2

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of silver nitrate and potassium phosphate are mixed.

▲ Figure 4.5 Vinegar and lemon juice are common household acids. Ammonia and baking soda (sodium bicarbonate) are common household bases.

4.3 | Acids, Bases, and Neutralization Reactions

Many acids and bases are industrial and household substances (**Figure 4.5**), and some are important components of biological fluids. Hydrochloric acid, for example, is an important industrial chemical and the main constituent of gastric juice in your stomach. Acids and bases are also common electrolytes.

Acids

As noted in Section 2.8, **acids** are substances that ionize in aqueous solution to form hydrogen ions $H^+(aq)$. Because a hydrogen atom consists of a proton and an electron,

 H^+ is simply a proton. Thus, acids are often called *proton donors*. Molecular models of four common acids are shown in \triangleright Figure 4.6.

Protons in aqueous solution are solvated by water molecules, just as other cations are [Figure 4.3(a)]. In writing chemical equations involving protons in water, therefore, we write $H^+(aq)$.

Molecules of different acids ionize to form different numbers of H^+ ions. Both HCl and HNO₃ are *monoprotic* acids, yielding one H^+ per molecule of acid. Sulfuric acid, H_2SO_4 , is a *diprotic* acid, one that yields two H^+ per molecule of acid. The ionization of H_2SO_4 and other diprotic acids occurs in two steps:

$$H_2SO_4(aq) \longrightarrow H^+(aq) + HSO_4^-(aq)$$
 [4.9]

$$HSO_4^-(aq) \rightleftharpoons H^+(aq) + SO_4^{2-}(aq)$$
 [4.10]

Although H_2SO_4 is a strong electrolyte, only the first ionization (Equation 4.9) is complete. Thus, aqueous solutions of sulfuric acid contain a mixture of $H^+(aq)$, $HSO_4^-(aq)$, and $SO_4^{2-}(aq)$.

The molecule CH₃COOH (acetic acid) that we have mentioned frequently is the primary component in vinegar. Acetic acid has four hydrogens, as Figure 4.6 shows, but only one of them, the H that is bonded to an oxygen in the —COOH group, is ionized in water. Thus, the H in the COOH group breaks its O—H bond in water. The three other hydrogens in acetic acid are bound to carbon and do not break their C—H bonds in water. The reasons for this difference are very interesting and will be discussed in Chapter 16.

Give It Some Thought

The structural formula of citric acid, a main component of citrus fruits, is

How many $H^+(aq)$ can be generated by each citric acid molecule dissolved in water?

Bases

Bases are substances that accept (react with) H^+ ions. Bases produce hydroxide ions (OH^-) when they dissolve in water. Ionic hydroxide compounds, such as NaOH, KOH, and $Ca(OH)_2$, are among the most common bases. When dissolved in water, they dissociate into ions, introducing OH^- ions into the solution.

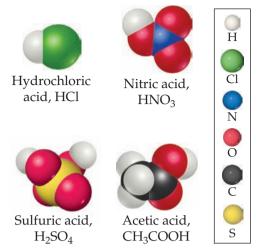

Compounds that do not contain OH^- ions can also be bases. For example, ammonia (NH_3) is a common base. When added to water, it accepts an H^+ ion from a water molecule and thereby produces an OH^- ion (\blacktriangleright Figure 4.7):

$$NH_3(aq) + H_2O(l) \implies NH_4^+(aq) + OH^-(aq)$$
 [4.11]

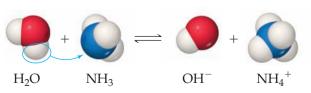

Ammonia is a weak electrolyte because only about 1% of the $\rm NH_3$ forms $\rm NH_4^+$ and $\rm OH^-$ ions.

Strong and Weak Acids and Bases

Acids and bases that are strong electrolytes (completely ionized in solution) are **strong acids** and **strong bases**. Those that are weak electrolytes (partly ionized) are **weak acids** and **weak bases**. When reactivity depends only on $H^+(aq)$ concentration, strong acids are more reactive

▲ Figure 4.6 Molecular models of four common acids.

▲ Figure 4.7 Proton transfer. An H₂O molecule acts as a proton donor (acid), and NH₃ acts as a proton acceptor (base). In aqueous solutions, only a fraction of the NH₃ molecules react with H₂O. Consequently, NH₃ is a weak electrolyte.

Table 4.2	Common	Strong	Acids	and	Bases
-----------	--------	--------	-------	-----	-------

Strong Acids Strong Bases Hydrochloric acid, HCl Hydrobromic acid, HBr Hydroiodic acid, HI Chloric acid, HClO₃ Perchloric acid, HClO₄ Nitric acid, HNO₃ Sulfuric acid (first proton), H₂SO₄ Strong Bases Group 1A metal hydroxides [LiOH, NaOH, KOH, RbOH, CsOH] Heavy group 2A metal hydroxides [Ca(OH)₂, Sr(OH)₂, Ba(OH)₂]

than weak acids. The reactivity of an acid, however, can depend on the anion as well as on $H^+(aq)$ concentration. For example, hydrofluoric acid (HF) is a weak acid (only partly ionized in aqueous solution), but it is very reactive and vigorously attacks many substances, including glass. This reactivity is due to the combined action of $H^+(aq)$ and $F^-(aq)$.

▲ Table 4.2 lists the strong acids and bases we are most likely to encounter. You need to commit this information to memory in order to correctly identify strong electrolytes and write net ionic equations. The brevity of this list tells us that most acids are weak. (For H_2SO_4 , as we noted earlier, only the first proton completely ionizes.) The only common strong bases are the common soluble metal hydroxides. The most common weak base is NH_3 , which reacts with water to form OH^- ions (Equation 4.11).

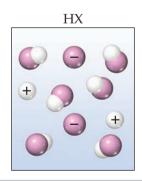

Give It Some Thought

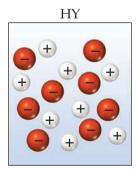

Why isn't $AI(OH)_3$ classified as a strong base?

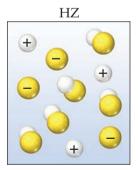

SAMPLE EXERCISE 4.5

Comparing Acid Strengths

The following diagrams represent aqueous solutions of acids HX, HY, and HZ, with water molecules omitted for clarity. Rank the acids from strongest to weakest.

SOLUTION

Analyze We are asked to rank three acids from strongest to weakest, based on schematic drawings of their solutions.

Plan We can determine the relative numbers of uncharged molecular species in the diagrams. The strongest acid is the one with the most H^+ ions and fewest undissociated molecules in solution. The weakest acid is the one with the largest number of undissociated molecules.

Solve The order is HY > HZ > HX. HY is a strong acid because it is totally ionized (no HY molecules in solution), whereas both HX and HZ are weak acids, whose solutions consist of a mixture of molecules and ions. Because HZ contains more H^+ ions and fewer molecules than HX, it is a stronger acid.

Practice Exercise 1

A set of aqueous solutions are prepared containing different acids at the same concentration: acetic acid, chloric acid and hydrobromic acid. Which solution(s) are the most electrically conductive? (a) chloric acid, (b) hydrobromic acid, (c) acetic acid, (d) both chloric acid and hydrobromic acid, (e) all three solutions have the same electrical conductivity.

Practice Exercise 2

Imagine a diagram showing $10~\mathrm{Na}^+$ ions and $10~\mathrm{OH}^-$ ions. If this solution were mixed with the one pictured above for HY, what species would be present in a diagram that represents the combined solutions after any possible reaction?

Identifying Strong and Weak Electrolytes

If we remember the common strong acids and bases (Table 4.2) and also remember that NH₃ is a weak base, we can make reasonable predictions about the electrolytic strength of a great number of water-soluble substances. ▼ Table 4.3 summarizes our observations about electrolytes. We first ask whether the substance is ionic or molecular. If it is ionic, it is a strong electrolyte. If the substance is molecular, we ask whether it is an acid or a base. (It is an acid if it either has H first in the chemical formula or contains a COOH group.) If it is an acid, we use Table 4.2 to determine whether it is a strong or weak electrolyte: All strong acids are strong electrolytes, and all weak acids are weak electrolytes. If an acid is not listed in Table 4.2, it is probably a weak acid and therefore a weak electrolyte.

If our substance is a base, we use Table 4.2 to determine whether it is a strong base. NH₃ is the only molecular base that we consider in this chapter, and it is a weak base; Table 4.3 tells us it is therefore a weak electrolyte. Finally, any molecular substance that we encounter in this chapter that is not an acid or NH₃ is probably a nonelectrolyte.

Table 4.3 Summary of the Electrolytic Behavior of Common Soluble Ionic and Molecular Compounds

	Strong Electrolyte	Weak Electrolyte	Nonelectrolyte
Ionic	All	None	None
Molecular	Strong acids (see Table 4.2)	Weak acids, weak bases	All other compounds

SAMPLE

EXERCISE 4.6 Identifying Strong, Weak, and Nonelectrolytes

Classify these dissolved substances as a strong electrolyte, weak electrolyte, or nonelectrolyte: CaCl₂, HNO₃, C₂H₅OH (ethanol), HCOOH (formic acid), KOH.

SOLUTION

Analyze We are given several chemical formulas and asked to classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte.

Plan The approach we take is outlined in Table 4.3. We can predict whether a substance is ionic or molecular based on its composition. As we saw in Section 2.7, most ionic compounds we encounter in this text are composed of a metal and a nonmetal, whereas most molecular compounds are composed only of nonmetals.

Solve Two compounds fit the criteria for ionic compounds: CaCl₂ and KOH. Because Table 4.3 tells us that all ionic compounds are strong electrolytes, that is how we classify these two substances. The three remaining compounds are molecular. Two of these molecular substances, HNO3 and HCOOH, are acids. Nitric acid, HNO₃, is a common strong acid, as shown in Table 4.2, and therefore is a strong electrolyte. Because most acids are weak acids, our best guess would be that HCOOH is a weak acid (weak electrolyte), which is in fact the case. The remaining molecular compound, C_2H_5OH , is neither an acid nor a base, so it is a nonelectrolyte.

Comment Although ethanol, C₂H₅OH, has an OH group, it is not a metal hydroxide and therefore not a base. Rather ethanol is a member of a class of organic compounds that have C — OH bonds, which are known as alcohols. (Section 2.9) Organic compounds containing the COOH group are called carboxylic acids (Chapter 16). Molecules that have this group are weak acids.

Practice Exercise 1

Which of these substances, when dissolved in water, is a strong electrolyte? (a) ammonia, (b) hydrofluoric acid, (c) folic acid, (d) sodium nitrate, (e) sucrose.

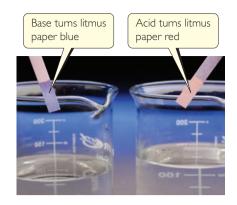

Practice Exercise 2

Consider solutions in which 0.1 mol of each of the following compounds is dissolved in 1 L of water: Ca(NO₃)₂ (calcium nitrate), C₆H₁₂O₆ (glucose), NaCH₃COO (sodium acetate), and CH₃COOH (acetic acid). Rank the solutions in order of increasing electrical conductivity, knowing that the greater the number of ions in solution, the greater the conductivity.

Neutralization Reactions and Salts

The properties of acidic solutions are quite different from those of basic solutions. Acids have a sour taste, whereas bases have a bitter taste.* Acids change the colors of certain dyes in a way that differs from the way bases affect the same dyes. This is the

^{*}Tasting chemical solutions is not a good practice. However, we have all had acids such as ascorbic acid (vitamin C), acetylsalicylic acid (aspirin), and citric acid (in citrus fruits) in our mouths, and we are familiar with their characteristic sour taste. Soaps, which are basic, have the characteristic bitter taste of bases.

▲ Figure 4.8 Litmus paper. Litmus paper is coated with dyes that change color in response to exposure to either acids or bases.

principle behind the indicator known as litmus paper (◀ Figure 4.8). In addition, acidic and basic solutions differ in chemical properties in several other important ways that we explore in this chapter and in later chapters.

When a solution of an acid and a solution of a base are mixed, a neutralization **reaction** occurs. The products of the reaction have none of the characteristic properties of either the acidic solution or the basic solution. For example, when hydrochloric acid is mixed with a solution of sodium hydroxide, the reaction is

$$\frac{\text{HCl}(aq) + \text{NaOH}(aq)}{\text{(acid)}} \xrightarrow{\text{HaO}(l)} \frac{\text{H2O}(l) + \text{NaCl}(aq)}{\text{(water)}}$$
(acid) (base) (water) (salt)

Water and table salt, NaCl, are the products of the reaction. By analogy to this reaction, the term salt has come to mean any ionic compound whose cation comes from a base (for example, Na⁺ from NaOH) and whose anion comes from an acid (for example, Cl⁻ from HCl). In general, a neutralization reaction between an acid and a metal hydroxide produces water and a salt.

Because HCl, NaOH, and NaCl are all water-soluble strong electrolytes, the complete ionic equation associated with Equation 4.12 is

$$H^{+}(aq) + Cl^{-}(aq) + Na^{+}(aq) + OH^{-}(aq) \longrightarrow H_{2}O(l) + Na^{+}(aq) + Cl^{-}(aq)$$
 [4.13]

Therefore, the net ionic equation is

$$H^{+}(aq) + OH^{-}(aq) \longrightarrow H_{2}O(l)$$
 [4.14]

Equation 4.14 summarizes the main feature of the neutralization reaction between any strong acid and any strong base: $H^+(aq)$ and $OH^-(aq)$ ions combine to form $H_2O(1)$.

▶ Figure 4.9 shows the neutralization reaction between hydrochloric acid and the water-insoluble base Mg(OH)₂:

Molecular equation:

$$Mg(OH)_2(s) + 2 HCl(aq) \longrightarrow MgCl_2(aq) + 2 H_2O(l)$$
 [4.15]

Net ionic equation:

$$Mg(OH)_2(s) + 2H^+(aq) \longrightarrow Mg^{2+}(aq) + 2H_2O(l)$$
 [4.16]

Notice that the OH ions (this time in a solid reactant) and H ions combine to form H₂O. Because the ions exchange partners, neutralization reactions between acids and metal hydroxides are metathesis reactions.

SAMPLE

EXERCISE 4.7 | Writing Chemical Equations for a Neutralization Reaction

For the reaction between aqueous solutions of acetic acid (CH₃COOH) and barium hydroxide, Ba(OH)₂, write (a) the balanced molecular equation, (b) the complete ionic equation, (c) the net ionic equation.

SOLUTION

Analyze We are given the chemical formulas for an acid and a base and asked to write a balanced molecular equation, a complete ionic equation, and a net ionic equation for their neutralization reaction. Plan As Equation 4.12 and the italicized statement that follows it indicate, neutralization reactions form two products, H₂O and a salt. We examine the cation of the base and the anion of the acid to determine the composition of the salt.

Solve

(a) The salt contains the cation of the base (Ba^{2+}) and the anion of the acid (CH₃COO⁻). Thus, the salt formula is Ba(CH₃COO)₂. According to Table 4.1, this compound is soluble in water. The unbalanced molecular equation for the neutralization reaction is To balance this equation, we must provide two molecules of CH₃COOH to furnish the two CH₃COO⁻ ions and to supply the two H⁺ ions needed to combine with the two

OH⁻ ions of the base. The balanced molecular equation is

$$CH_3COOH(aq) + Ba(OH)_2(aq) \longrightarrow H_2O(l) + Ba(CH_3COO)_2(aq)$$

$$2 \text{ CH}_3\text{COOH}(aq) + \text{Ba}(\text{OH})_2(aq) \longrightarrow 2 \text{ H}_2\text{O}(l) + \text{Ba}(\text{CH}_3\text{COO})_2(aq)$$

- (b) To write the complete ionic equation, we identify the strong electrolytes and break them into ions. In this case Ba(OH)₂ and Ba(CH₃COO)₂ are both water-soluble ionic compounds and hence strong electrolytes. Thus, the complete ionic equation is
- (c) Eliminating the spectator ion, Ba²⁺, and simplifying coefficients gives the net ionic equation:

$$2 \text{ CH}_3\text{COOH}(aq) + \text{Ba}^{2+}(aq) + 2 \text{ OH}^-(aq) \longrightarrow \\ 2 \text{ H}_2\text{O}(l) + \text{Ba}^{2+}(aq) + 2 \text{ CH}_3\text{COO}^-(aq)$$

$$CH_3COOH(aq) + OH^-(aq) \longrightarrow H_2O(l) + CH_3COO^-(aq)$$

(e) $NH_4^+(aq) + NO_3^-(aq) \longrightarrow NH_4NO_3(aq)$

Check We can determine whether the molecular equation is balanced by counting the number of atoms of each kind on both sides of the arrow (10 H, 6 O, 4 C, and 1 Ba on each side). However, it is often easier to check equations by counting groups: There are $2 \text{ CH}_3\text{COO}$ groups, as well as 1 Ba, and 4 additional H atoms and 2 additional O atoms on each side of the equation. The net ionic equation checks out because the numbers of each kind of element and the net charge are the same on both sides of the equation.

Practice Exercise 1

Which is the correct net ionic equation for the reaction of aqueous ammonia with nitric acid?

(a)
$$NH_4^+(aq) + H^+(aq) \longrightarrow NH_5^{2+}(aq)$$

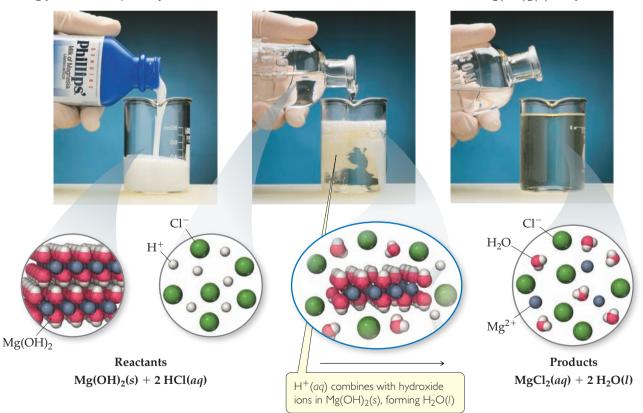

(b) $NH_3(aq) + NO_3^-(aq) \longrightarrow NH_2^-(aq) + HNO_3(aq)$
(c) $NH_2^-(aq) + H^+(aq) \longrightarrow NH_3(aq)$
(d) $NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$

Practice Exercise 2

For the reaction of phosphorous acid (H_3PO_3) and potassium hydroxide (KOH), write (a) the balanced molecular equation and (b) the net ionic equation.

A GO FIGURE

Adding just a few drops of hydrochloric acid would not be sufficient to dissolve all the $Mg(OH)_2(s)$. Why not?

▲ Figure 4.9 Neutralization reaction between $Mg(OH)_2(s)$ and hydrochloric acid. Milk of magnesia is a suspension of water-insoluble magnesium hydroxide, $Mg(OH)_2(s)$, in water. When sufficient hydrochloric acid, HCI(aq), is added, a reaction ensues that leads to an aqueous solution containing $Mg^{2+}(aq)$ and $CI^-(aq)$ ions.

Neutralization Reactions with Gas Formation

Many bases besides OH^- react with H^+ to form molecular compounds. Two of these that you might encounter in the laboratory are the sulfide ion and the carbonate ion. Both of these anions react with acids to form gases that have low solubilities in water. Hydrogen sulfide (H_2S), the substance that gives rotten eggs their foul odor and that is emitted in deep sea vents, forms when an acid such as HCl(aq) reacts with a metal sulfide such as Na_2S :

Molecular equation:

$$2 \operatorname{HCl}(aq) + \operatorname{Na_2S}(aq) \longrightarrow \operatorname{H_2S}(g) + 2 \operatorname{NaCl}(aq)$$
 [4.17]

Net ionic equation:

$$2 \operatorname{H}^{+}(aq) + \operatorname{S}^{2-}(aq) \longrightarrow \operatorname{H}_{2}\operatorname{S}(q)$$
 [4.18]

Carbonates and bicarbonates react with acids to form $CO_2(g)$. Reaction of CO_3^{2-} or HCO_3^- with an acid first gives carbonic acid (H_2CO_3) . For example, when hydrochloric acid is added to sodium bicarbonate, the reaction is

$$HCl(aq) + NaHCO_3(aq) \longrightarrow NaCl(aq) + H_2CO_3(aq)$$
 [4.19]

Carbonic acid is unstable. If present in solution in sufficient concentrations, it decomposes to H_2O and CO_2 , which escapes from the solution as a gas:

$$H_2CO_3(aq) \longrightarrow H_2O(l) + CO_2(g)$$
 [4.20]

The overall reaction is summarized by the following equations:

Molecular equation:

$$HCl(aq) + NaHCO_3(aq) \longrightarrow NaCl(aq) + H_2O(l) + CO_2(g)$$
 [4.21]

Net ionic equation:

$$H^+(aq) + HCO_3^-(aq) \longrightarrow H_2O(l) + CO_2(g)$$
 [4.22]

Both NaHCO₃(s) and Na₂CO₃(s) are used as neutralizers in acid spills; either salt is added until the fizzing caused by CO₂(g) formation stops. Sometimes sodium bicarbonate is used as an antacid to soothe an upset stomach. In that case the HCO₃⁻ reacts with stomach acid to form CO₂(g).

Give It Some Thought

By analogy to examples given in the text, predict what gas forms when $Na_2SO_3(s)$ reacts with HCI(aq).

4.4 | Oxidation-Reduction Reactions

In precipitation reactions, cations and anions come together to form an insoluble ionic compound. In neutralization reactions, protons are transferred from one reactant to another. Now let's consider a third kind of reaction, one in which electrons are transferred from one reactant to another. Such reactions are called either **oxidation-reduction reactions** or **redox reactions**. In this chapter we concentrate on redox reactions where one of the reactants is a metal in its elemental form. Redox reactions are critical in understanding many biological and geological processes in the world around us, including those occurring in deep sea vents; they also form the basis for energy-related technologies such as batteries and fuel cells (Chapter 20).

Oxidation and Reduction

One of the most familiar redox reactions is *corrosion* of a metal (**Figure 4.11**). In some instances corrosion is limited to the surface of the metal, as is the case with the green coating that forms on copper roofs and statues. In other instances the corrosion

Chemistry Put to Work

Antacids

Your stomach secretes acids to help digest foods. These acids, which include hydrochloric acid, contain about 0.1 mol of H^+ per liter of solution. The stomach and digestive tract are normally protected from the corrosive effects of stomach acid by a mucosal lining. Holes can develop in this lining, however, allowing the acid to attack the underlying tissue, causing painful damage. These holes, known as ulcers, can be caused by the secretion of excess acids and/or by a weakness in the digestive lining. Many peptic ulcers are caused by infection by the bacterium $Helicobacter\ pylori$. Between 10 and 20% of Americans suffer from ulcers at some point in their lives. Many others experience

▲ Figure 4.10 Antacids. These products all serve as acid-neutralizing agents in the stomach.

occasional indigestion, heartburn, or reflux due to digestive acids entering the esophagus.

The problem of excess stomach acid can be addressed by (1) removing the excess acid or (2) decreasing the production of acid. Substances that remove excess acid are called *antacids*, whereas those that decrease acid production are called *acid inhibitors*. ◀ Figure 4.10 shows several common over-the-counter antacids, which usually contain hydroxide, carbonate, or bicarbonate ions (▼ Table 4.4). Antiulcer drugs, such as Tagamet® and Zantac®, are acid inhibitors. They act on acid-producing cells in the lining of the stomach. Formulations that control acid in this way are now available as over-the-counter drugs.

goes deeper, eventually compromising the structural integrity of the metal as happens with the rusting of iron.

Corrosion is the conversion of a metal into a metal compound, by a reaction between the metal and some substance in its environment. When a metal corrodes, each metal atom loses electrons and so forms a cation, which can combine with an anion to form an ionic compound. The green coating on the Statue of Liberty contains Cu^{2+} combined with carbonate and hydroxide anions; rust contains Fe^{3+} combined with oxide and hydroxide anions; and silver tarnish contains Ag^+ combined with sulfide anions.

When an atom, ion, or molecule becomes more positively charged (that is, when it loses electrons), we say that it has been *oxidized*. Loss of electrons by a substance is

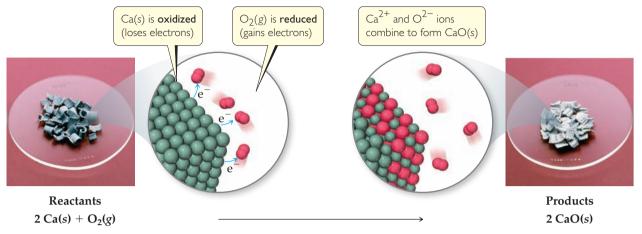

▲ Figure 4.11 Familiar corrosion products. (a) A green coating forms when copper is oxidized. (b) Rust forms when iron corrodes. (c) A black tarnish forms as silver corrodes.

^{*}Bunke, B. "Inhibition of pepsin proteolytic activity by some common antacids." NCBI. 1962.

▲ GO FIGURE

How many electrons does each oxygen atom gain during the course of this reaction?

▲ Figure 4.12 Oxidation of calcium metal by molecular oxygen.

called **oxidation**. The term *oxidation* is used because the first reactions of this sort to be studied were reactions with oxygen. Many metals react directly with O_2 in air to form metal oxides. In these reactions the metal loses electrons to oxygen, forming an ionic compound of the metal ion and oxide ion. The familiar example of rusting involves the reaction between iron metal and oxygen in the presence of water. In this process Fe is *oxidized* (loses electrons) to form Fe^{3+} .

The reaction between iron and oxygen tends to be relatively slow, but other metals, such as the alkali and alkaline earth metals, react quickly upon exposure to air.

A Figure 4.12 shows how the bright metallic surface of calcium tarnishes as CaO forms in the reaction

$$2 \operatorname{Ca}(s) + \operatorname{O}_2(g) \longrightarrow 2 \operatorname{CaO}(s)$$
 [4.23]

In this reaction Ca is oxidized to Ca^{2+} and neutral O_2 is transformed to O^{2-} ions. When an atom, ion, or molecule becomes more negatively charged (gains electrons), we say that it is *reduced*. The gain of electrons by a substance is called **reduction**. When one reactant loses electrons (that is, when it is oxidized), another reactant must gain them. In other words, oxidation of one substance must be accompanied by reduction of some other substance. The oxidation involves transfer of electrons from the calcium metal to the O_2 , leading to formation of CaO.

Oxidation Numbers

Before we can identify an oxidation-reduction reaction, we must have a bookkeeping system—a way of keeping track of electrons gained by the substance being reduced and electrons lost by the substance being oxidized. The concept of oxidation numbers (also called *oxidation states*) was devised as a way of doing this. Each atom in a neutral substance or ion is assigned an **oxidation number**. For monatomic ions the oxidation number is the same as the charge. For neutral molecules and polyatomic ions, the oxidation number of a given atom is a hypothetical charge. This charge is assigned by artificially dividing up the electrons among the atoms in the molecule or ion. We use the following rules for assigning oxidation numbers:

- 1. For an atom in its elemental form, the oxidation number is always zero. Thus, each H atom in the H_2 molecule has an oxidation number of 0 and each P atom in the P_4 molecule has an oxidation number of 0.
- **2.** For any monatomic ion the oxidation number equals the ionic charge. Thus, K^+ has an oxidation number of +1, S^{2-} has an oxidation number of -2, and so forth.

In ionic compounds the alkali metal ions (group 1A) always have a 1+ charge and therefore an oxidation number of +1. The alkaline earth metals (group 2A) are always +2, and aluminum (group 3A) is always +3 in ionic compounds. (In writing oxidation numbers we will write the sign before the number to distinguish them from the actual electronic charges, which we write with the number first.)

- **3.** *Nonmetals* usually have negative oxidation numbers, although they can sometimes be positive:
 - (a) The oxidation number of **oxygen** is usually -2 in both ionic and molecular compounds. The major exception is in compounds called peroxides, which contain the O_2^{2-} ion, giving each oxygen an oxidation number of -1.
 - **(b)** The oxidation number of **hydrogen** is usually +1 when bonded to nonmetals and -1 when bonded to metals (for example, metal hydrides such as sodium hydride, NaH).
 - (c) The oxidation number of **fluorine** is -1 in all compounds. The other **halogens** have an oxidation number of -1 in most binary compounds. When combined with oxygen, as in oxyanions, however, they have positive oxidation states.
- **4.** The sum of the oxidation numbers of all atoms in a neutral compound is zero. The sum of the oxidation numbers in a polyatomic ion equals the charge of the ion. For example, in the hydronium ion H_3O^+ , which is a more accurate description of $H^+(aq)$, the oxidation number of each hydrogen is +1 and that of oxygen is -2. Thus, the sum of the oxidation numbers is 3(+1) + (-2) = +1, which equals the net charge of the ion. This rule is useful in obtaining the oxidation number of one atom in a compound or ion if you know the oxidation numbers of the other atoms, as illustrated in Sample Exercise 4.8.

Give It Some Thought

What is the oxidation number of nitrogen (a) in aluminum nitride, AIN, and (b) in nitric acid, HNO_3 ?

SAMPLE EXERCISE 4.8 Determining Oxidation Numbers

Determine the oxidation number of sulfur in (a) H_2S , (b) S_8 , (c) SCl_2 , (d) Na_2SO_3 , (e) SO_4^{2-} .

SOLUTION

Analyze We are asked to determine the oxidation number of sulfur in two molecular species, in the elemental form, and in two substances containing ions.

Plan In each species the sum of oxidation numbers of all the atoms must equal the charge on the species. We will use the rules outlined previously to assign oxidation numbers.

Solve

- (a) When bonded to a nonmetal, hydrogen has an oxidation number of +1. Because the H_2S molecule is neutral, the sum of the oxidation numbers must equal zero. Letting x equal the oxidation number of S, we have 2(+1) + x = 0. Thus, S has an oxidation number of -2.
- (b) Because S₈ is an elemental form of sulfur, the oxidation number of S is 0.
- (c) Because SCl_2 is a binary compound, we expect chlorine to have an oxidation number of -1. The sum of the oxidation numbers must equal zero. Letting x equal the oxidation number of S, we have x + 2(-1) = 0. Consequently, the oxidation number of S must be +2.
- (d) Sodium, an alkali metal, always has an oxidation number of +1 in its compounds. Oxygen commonly has an oxidation

- state of -2. Letting x equal the oxidation number of S, we have 2(+1) + x + 3(-2) = 0. Therefore, the oxidation number of S in this compound (Na₂SO₃) is +4.
- (e) The oxidation state of O is -2. The sum of the oxidation numbers equals -2, the net charge of the $SO_4^{\ 2^-}$ ion. Thus, we have x + 4(-2) = -2. From this relation we conclude that the oxidation number of S in this ion is +6.

Comment These examples illustrate that the oxidation number of a given element depends on the compound in which it occurs. The oxidation numbers of sulfur, as seen in these examples, range from -2 to +6.

Practice Exercise 1

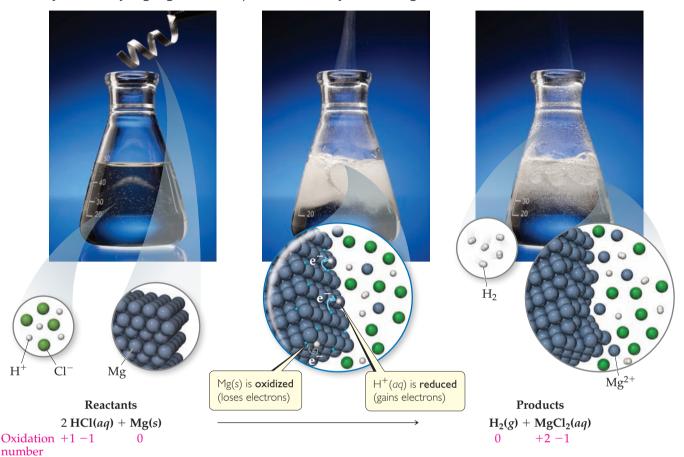

In which compound is the oxidation state of oxygen -1? (a) O_2 , (b) H_2O , (c) H_2SO_4 , (d) H_2O_2 , (e) KCH_3COO .

Practice Exercise 2

What is the oxidation state of the boldfaced element in (a) P_2O_5 , (b) NaH, (c) $Cr_2O_7^{2-}$, (d) $SnBr_4$, (e) BaO_2 ?

▲ GO FIGURE

How many moles of hydrogen gas would be produced for every mole of magnesium added into the HCI solution?

▲ Figure 4.13 Reaction of magnesium metal with hydrochloric acid. The metal is readily oxidized by the acid, producing hydrogen gas, $H_2(g)$, and $MgCl_2(aq)$.

Oxidation of Metals by Acids and Salts

The reaction between a metal and either an acid or a metal salt conforms to the general pattern

$$A + BX \longrightarrow AX + B$$

$$Examples: Zn(s) + 2 HBr(aq) \longrightarrow ZnBr_2(aq) + H_2(g)$$

$$Mn(s) + Pb(NO_3)_2(aq) \longrightarrow Mn(NO_3)_2(aq) + Pb(s)$$

$$[4.24]$$

These reactions are called **displacement reactions** because the ion in solution is *displaced* (replaced) through oxidation of an element.

Many metals undergo displacement reactions with acids, producing salts and hydrogen gas. For example, magnesium metal reacts with hydrochloric acid to form magnesium chloride and hydrogen gas (**A Figure 4.13**):

The oxidation number of Mg changes from 0 to +2, an increase that indicates the atom has lost electrons and has therefore been oxidized. The oxidation number of H^+ in the acid decreases from +1 to 0, indicating that this ion has gained electrons and has

therefore been reduced. Chlorine has an oxidation number of -1 both before and after the reaction, indicating that it is neither oxidized nor reduced. In fact the Cl^- ions are spectator ions, dropping out of the net ionic equation:

$$Mg(s) + 2 H^{+}(aq) \longrightarrow Mg^{2+}(aq) + H_2(g)$$
 [4.26]

Metals can also be oxidized by aqueous solutions of various salts. Iron metal, for example, is oxidized to Fe^{2+} by aqueous solutions of Ni^{2+} such as $Ni(NO_3)_2(aq)$:

Molecular equation:
$$Fe(s) + Ni(NO_3)_2(aq) \longrightarrow Fe(NO_3)_2(aq) + Ni(s)$$
 [4.27]

Net ionic equation:
$$Fe(s) + Ni^{2+}(aq) \longrightarrow Fe^{2+}(aq) + Ni(s)$$
 [4.28]

The oxidation of Fe to Fe²⁺ in this reaction is accompanied by the reduction of Ni²⁺ to Ni. Remember: *Whenever one substance is oxidized, another substance must be reduced.*

SAMPLE EXERCISE 4.9 Writing Equations for Oxidation-Reduction Reactions

Write the balanced molecular and net ionic equations for the reaction of aluminum with hydrobromic acid.

SOLUTION

Analyze We must write two equations—molecular and net ionic—for the redox reaction between a metal and an acid.

Plan Metals react with acids to form salts and H_2 gas. To write the balanced equations, we must write the chemical formulas for the two reactants and then determine the formula of the salt, which is composed of the cation formed by the metal and the anion of the acid.

Solve The reactants are Al and HBr. The cation formed by Al is Al^{3+} , and the anion from hydrobromic acid is Br^- . Thus, the salt formed in the reaction is $AlBr_3$. Writing the reactants and products and then balancing the equation gives the molecular equation:

$$2 \text{ Al}(s) + 6 \text{ HBr}(aq) \longrightarrow 2 \text{ AlBr}_3(aq) + 3 \text{ H}_2(g)$$

Both HBr and ${\rm AlBr_3}$ are soluble strong electrolytes. Thus, the complete ionic equation is

$$2 \text{ Al}(s) + 6 \text{ H}^{+}(aq) + 6 \text{ Br}^{-}(aq) \longrightarrow$$

 $2 \text{ Al}^{3+}(aq) + 6 \text{ Br}^{-}(aq) + 3 \text{ H}_{2}(g)$

Because Br is a spectator ion, the net ionic equation is

$$2 \text{ Al}(s) + 6 \text{ H}^{+}(aq) \longrightarrow 2 \text{ Al}^{3+}(aq) + 3 \text{ H}_{2}(g)$$

Comment The substance oxidized is the aluminum metal because its oxidation state changes from 0 in the metal to +3 in the cation, thereby increasing in oxidation number. The H^+ is reduced because its oxidation state changes from +1 in the acid to 0 in H_2 .

Practice Exercise 1

Which of the following statements is true about the reaction between zinc and copper sulfate? (a) Zinc is oxidized, and copper ion is reduced. (b) Zinc is reduced, and copper ion is oxidized. (c) All reactants and products are soluble strong electrolytes. (d) The oxidation state of copper in copper sulfate is 0. (e) More than one of the previous choices are true.

Practice Exercise 2

(a) Write the balanced molecular and net ionic equations for the reaction between magnesium and cobalt(II) sulfate. (b) What is oxidized and what is reduced in the reaction?

The Activity Series

Can we predict whether a certain metal will be oxidized either by an acid or by a particular salt? This question is of practical importance as well as chemical interest. According to Equation 4.27, for example, it would be unwise to store a solution of nickel nitrate in an iron container because the solution would dissolve the container. When a metal is oxidized, it forms various compounds. Extensive oxidation can lead to the failure of metal machinery parts or the deterioration of metal structures.

Different metals vary in the ease with which they are oxidized. Zn is oxidized by aqueous solutions of Cu²⁺, for example, but Ag is not. Zn, therefore, loses electrons more readily than Ag; that is, Zn is easier to oxidize than Ag.

A list of metals arranged in order of decreasing ease of oxidation, such as in **Table 4.5**, is called an **activity series**. The metals at the top of the table, such as the alkali metals and the alkaline earth metals, are most easily oxidized; that is, they react most readily to form compounds. They are called the *active metals*. The metals at the bottom of the activity series, such as the transition elements from groups 8B and 1B, are very stable and form compounds less readily. These metals, which are used to make coins and jewelry, are called *noble metals* because of their low reactivity.

The activity series can be used to predict the outcome of reactions between metals and either metal salts or acids. Any metal on the list can be oxidized by the ions of

Table 4.5 Activity Series of Metals in Aqueous Solution				
Metal	Oxidation Reaction			
Lithium	$Li(s) \longrightarrow Li^+(aq) + e^-$			
Potassium	$K(s) \longrightarrow K^+(aq) + e^-$			
Barium	$Ba(s) \longrightarrow Ba^{2+}(aq) + 2e^{-}$			
Calcium	$Ca(s) \longrightarrow Ca^{2+}(aq) + 2e^{-}$			
Sodium	$Na(s) \longrightarrow Na^{+}(aq) + e^{-}$	1		
Magnesium	$Mg(s) \longrightarrow Mg^{2+}(aq) + 2e^{-}$			
Aluminum	$Al(s) \longrightarrow Al^{3+}(aq) + 3e^{-}$			
Manganese	$Mn(s) \longrightarrow Mn^{2+}(aq) + 2e^{-}$	SS		
Zinc	$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^{-}$	rease		
Chromium	$Cr(s) \longrightarrow Cr^{3+}(aq) + 3e^{-}$	Ease of oxidation increases		
Iron	$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^{-}$	tion		
Cobalt	$Co(s) \longrightarrow Co^{2+}(aq) + 2e^{-}$	xida		
Nickel	$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^{-}$	o Jo		
Tin	$\operatorname{Sn}(s) \longrightarrow \operatorname{Sn}^{2+}(aq) + 2e^{-}$	ase		
Lead	$Pb(s) \longrightarrow Pb^{2+}(aq) + 2e^{-}$	1		
Hydrogen	$H_2(g) \longrightarrow 2 H^+(aq) + 2e^-$			
Copper	$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^{-}$			
Silver	$Ag(s) \longrightarrow Ag^+(aq) + e^-$			
Mercury	$Hg(l) \longrightarrow Hg^{2+}(aq) + 2e^{-}$			
Platinum	$Pt(s) \longrightarrow Pt^{2+}(aq) + 2e^{-}$			
Gold	$Au(s) \longrightarrow Au^{3+}(aq) + 3e^{-}$			

Table 4.5 Activity Series of Metals in Aqueous Solution

elements below it. For example, copper is above silver in the series. Thus, copper metal is oxidized by silver ions:

$$Cu(s) + 2 Ag^{+}(aq) \longrightarrow Cu^{2+}(aq) + 2 Ag(s)$$
 [4.29]

The oxidation of copper to copper ions is accompanied by the reduction of silver ions to silver metal. The silver metal is evident on the surface of the copper wire in ▶ Figure 4.14. The copper(II) nitrate produces a blue color in the solution, as can be seen most clearly in the photograph on the right of Figure 4.14.

Give It Some Thought

Does a reaction occur (a) when an aqueous solution of $NiCl_2(aq)$ is added to a test tube containing strips of metallic zinc, and (b) when $NiCl_2(aq)$ is added to a test tube containing $Zn(NO_3)_2(aq)$?

Only metals above hydrogen in the activity series are able to react with acids to form H_2 . For example, Ni reacts with HCl(aq) to form H_2 :

$$Ni(s) + 2 HCl(aq) \longrightarrow NiCl_2(aq) + H_2(g)$$
 [4.30]

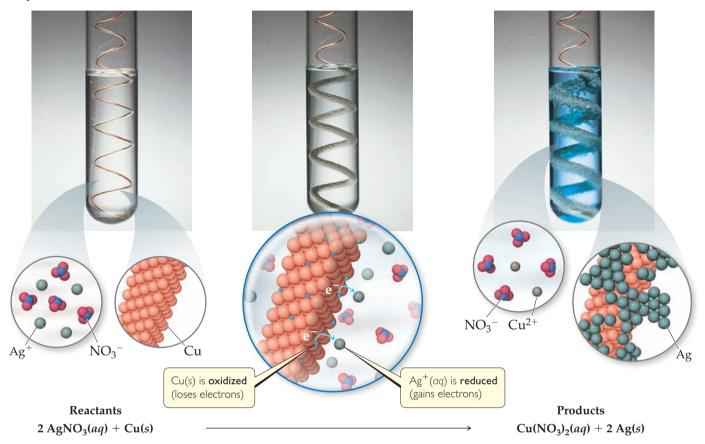

Because elements below hydrogen in the activity series are not oxidized by H^+ , Cu does not react with HCl(aq). Interestingly, copper does react with nitric acid, as shown in Figure 1.11, but the reaction is not oxidation of Cu by H^+ ions. Instead, the metal is oxidized to Cu^{2^+} by the nitrate ion, accompanied by the formation of brown nitrogen dioxide, $NO_2(g)$:

$$Cu(s) + 4 HNO_3(aq) \longrightarrow Cu(NO_3)_2(aq) + 2 H_2O(l) + 2 NO_2(g)$$
 [4.31]

As the copper is oxidized in this reaction, NO_3^- , where the oxidation number of nitrogen is +5, is reduced to NO_2 , where the oxidation number of nitrogen is +4. We will examine reactions of this type in Chapter 20.

▲ GO FIGURE

Why does this solution turn blue?

▲ Figure 4.14 Reaction of copper metal with silver ion. When copper metal is placed in a solution of silver nitrate, a redox reaction forms silver metal and a blue solution of copper(II) nitrate.

SAMPLE EXERCISE 4.10 Determining When an Oxidation-Reduction Reaction Can Occur

Will an aqueous solution of iron(II) chloride oxidize magnesium metal? If so, write the balanced molecular and net ionic equations for the reaction.

SOLUTION

Analyze We are given two substances—an aqueous salt, FeCl₂, and a metal, Mg—and asked if they react with each other.

Plan A reaction occurs if the reactant that is a metal in its elemental form (Mg) is located above the reactant that is a metal in its oxidized form (Fe^{2+}) in Table 4.5. If the reaction occurs, the Fe^{2+} ion in $FeCl_2$ is reduced to Fe, and the Mg is oxidized to Mg^{2+} .

Solve Because Mg is above Fe in the table, the reaction occurs. To write the formula for the salt produced in the reaction, we must remember the charges on common ions. Magnesium is always present in compounds as Mg^{2+} ; the chloride ion is Cl^- . The magnesium salt formed in the reaction is $MgCl_2$, meaning the balanced molecular equation is

$$Mg(s) + FeCl_2(aq) \longrightarrow MgCl_2(aq) + Fe(s)$$

Both $FeCl_2$ and $MgCl_2$ are soluble strong electrolytes and can be written in ionic form, which shows us that Cl^- is a spectator ion in the reaction. The net ionic equation is

$$Mg(s) + Fe^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Fe(s)$$

The net ionic equation shows that Mg is oxidized and Fe^{2+} is reduced in this reaction.

Check Note that the net ionic equation is balanced with respect to both charge and mass.

Practice Exercise 1

Which of these metals is the easiest to oxidize? (a) gold, (b) lithium, (c) iron, (d) sodium, (e) aluminum.

Practice Exercise 2

Which of the following metals will be oxidized by $Pb(NO_3)_2$: Zn, Cu, Fe?

Strategies in Chemistry

Analyzing Chemical Reactions

In this chapter you have been introduced to a great number of chemical reactions. It's not easy to get a "feel" for what happens when chemicals react. One goal of this textbook is to help you become more adept at predicting the outcomes of reactions. The key to gaining this "chemical intuition" is to learn how to categorize reactions.

Attempting to memorize individual reactions would be a futile task. It is far more fruitful to recognize patterns to determine the general category of a reaction, such as metathesis or oxidation-reduction. When faced with the challenge of predicting the outcome of a chemical reaction, ask yourself the following questions:

- What are the reactants?
- Are they electrolytes or nonelectrolytes?
- Are they acids or bases?
- If the reactants are electrolytes, will metathesis produce a precipitate? Water? A gas?
- If metathesis cannot occur, can the reactants engage in an oxidation-reduction reaction? This requires that there be both a reactant that can be oxidized and a reactant that can be reduced.

Being able to predict what happens during a reaction follows from asking basic questions like the ones above. Each question narrows the set of possible outcomes, steering you ever closer to a likely outcome. Your prediction might not always be entirely correct, but if you keep your wits about you, you will not be far off. As you gain experience, you will begin to look for reactants that might not be immediately obvious, such as water from the solution or oxygen from the atmosphere. Because proton transfer (acid-base) and electron transfer (oxidation-reduction) are involved in a huge number of chemical reactions, knowing the hallmarks of such reactions will mean you are well on your way to becoming an excellent chemist!

The laboratory is the best place to learn how to think like a chemist. One of the greatest tools available to chemists is experimentation. If you perform an experiment in which two solutions are mixed, you can make observations that help you understand what is happening. Consider, for example, the precipitation experiment in Figure 4.4. Although you might use Table 4.1 to predict whether a precipitate will form, it is much more exciting to actually see the precipitate form! Careful observation in the laboratory portion of the course will make your lecture material both more meaningful and easier to master.

4.5 | Concentrations of Solutions

Scientists use the term **concentration** to designate the amount of solute dissolved in a given quantity of solvent or quantity of solution. The greater the amount of solute dissolved in a certain amount of solvent, the more concentrated the resulting solution. In chemistry we often need to express the concentrations of solutions quantitatively.

Molarity

Molarity (symbol *M*) expresses the concentration of a solution as the number of moles of solute in a liter of solution (soln):

Molarity =
$$\frac{\text{moles solute}}{\text{volume of solution in liters}}$$
 [4.32]

A 1.00 molar solution (written 1.00 M) contains 1.00 mol of solute in every liter of solution. \blacktriangleright **Figure 4.15** shows the preparation of 0.250 L of a 1.00 M solution of CuSO₄. The molarity of the solution is $(0.250 \text{ mol CuSO}_4)/(0.250 \text{ L soln}) = 1.00 M$.

Give It Some Thought

Which is more concentrated, a solution prepared by dissolving $21.0 \, \text{g}$ of NaF (0.500 mol) in enough water to make 500 mL of solution or a solution prepared by dissolving $10.5 \, \text{g}$ (0.250 mol) of NaF in enough water to make $100 \, \text{mL}$ of solution?

SAMPLE EXERCISE 4.11 Calculating Molarity

Calculate the molarity of a solution made by dissolving 23.4 g of sodium sulfate (Na_2SO_4) in enough water to form 125 mL of solution.

SOLUTION

Analyze We are given the number of grams of solute (23.4 g), its chemical formula (Na_2SO_4) , and the volume of the solution (125 mL) and asked to calculate the molarity of the solution.

Plan We can calculate molarity using Equation 4.32. To do so, we must convert the number of grams of solute to moles and the volume of the solution from milliliters to liters.

Solve The number of moles of Na₂SO₄ is obtained by using its molar mass:

$$Moles Na_2SO_4 = (23.4 \text{ g-Na}_2SO_4) \left(\frac{1 \text{ mol Na}_2SO_4}{142.1 \text{ g-Na}_2SO_4}\right) = 0.165 \text{ mol Na}_2SO_4$$

Converting the volume of the solution to liters: Liters soln =
$$(125 \text{ mH}) \left(\frac{1 \text{ L}}{1000 \text{ mH}} \right) = 0.125 \text{ L}$$

Molarity =
$$\frac{0.165 \text{ mol Na}_2 \text{SO}_4}{0.125 \text{ L soln}} = 1.32 \frac{\text{mol Na}_2 \text{SO}_4}{\text{L soln}} = 1.32 M$$

Check Because the numerator is only slightly larger than the denominator, it is reasonable for the answer to be a little over 1 M. The units (mol/L) are appropriate for molarity, and three significant figures are appropriate for the answer because each of the initial pieces of data had three significant figures.

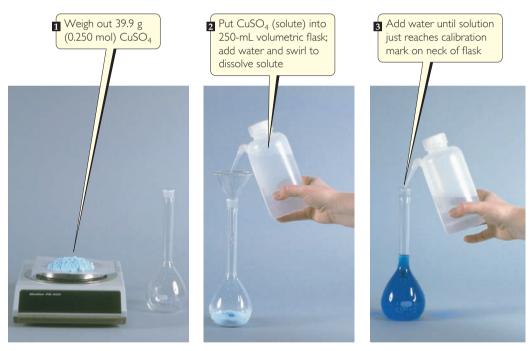

solution? (a) 13.4 M, (b) 7.43 \times 10⁻² M, (c) 3.91 \times 10⁻² M (d) $7.43 \times 10^{-5} M$ (e) $3.91 \times 10^{-5} M$.

Practice Exercise 2

Calculate the molarity of a solution made by dissolving 5.00 g of glucose (C₆H₁₂O₆) in sufficient water to form exactly 100 mL of

Practice Exercise 1

What is the molarity of a solution that is made by dissolving 3.68 g of sucrose (C₁₂H₂₂O₁₁) in sufficient water to form 275.0 mL of

▲ Figure 4.15 Preparing 0.250 L of a 1.00 M solution of CuSO₄.

Expressing the Concentration of an Electrolyte

In biology, the total concentration of ions in solution is very important in metabolic and cellular processes. When an ionic compound dissolves, the relative concentrations of the ions in the solution depend on the chemical formula of the compound. For example, a 1.0 M solution of NaCl is 1.0 M in Na⁺ ions and 1.0 M in Cl⁻ ions, and a 1.0 M solution of Na_2SO_4 is 2.0 M in Na^+ ions and 1.0 M in SO_4^{2-} ions. Thus, the concentration of an electrolyte solution can be specified either in terms of the compound used to make the solution (1.0 M Na₂SO₄) or in terms of the ions in the solution (2.0 M Na⁺ and $1.0 M SO_4^{2-}$).

SAMPLE EXERCISE 4.12 Calculating Molar Concentrations of Ions

What is the molar concentration of each ion present in a $0.025\,M$ aqueous solution of calcium nitrate?

SOLUTION

Analyze We are given the concentration of the ionic compound used to make the solution and asked to determine the concentrations of the ions in the solution.

Plan We can use the subscripts in the chemical formula of the compound to determine the relative ion concentrations.

Solve Calcium nitrate is composed of calcium ions (Ca^{2+}) and nitrate ions (NO_3^-) , so its chemical formula is $Ca(NO_3)_2$. Because there are two NO_3^- ions for each Ca^{2+} ion, each mole of $Ca(NO_3)_2$ that dissolves dissociates into 1 mol of Ca^{2+} and 2 mol of NO_3^- . Thus, a solution that is 0.025 M in $Ca(NO_3)_2$ is 0.025 M in Ca^{2+} and 2 \times 0.025 M = 0.050 M in NO_3^- :

$$\frac{\text{mol NO}_{3}^{-}}{\text{L}} = \left(\frac{0.025 \text{ mol Ca}(\text{NO}_{3})_{2}}{\text{L}}\right) \left(\frac{2 \text{ mol NO}_{3}^{-}}{1 \text{ mol Ca}(\text{NO}_{3})_{2}}\right) = 0.050 \text{ M}$$

Check The concentration of NO_3^- ions is twice that of Ca^{2+} ions, as the subscript 2 after the NO_3^- in the chemical formula $Ca(NO_3)_2$ suggests.

Practice Exercise 1

What is the ratio of the concentration of potassium ions to the concentration of carbonate ions in a 0.015 *M* solution of potassium carbonate? (a) 1:0.015, (b) 0.015:1, (c) 1:1, (d) 1:2, (e) 2:1.

Practice Exercise 2

What is the molar concentration of K^+ ions in a 0.015 M solution of potassium carbonate?

Interconverting Molarity, Moles, and Volume

If we know any two of the three quantities in Equation 4.32, we can calculate the third. For example, if we know the molarity of an HNO_3 solution to be 0.200 M, which means 0.200 mol of HNO_3 per liter of solution, we can calculate the number of moles of solute in a given volume, say 2.0 L. Molarity therefore is a conversion factor between volume of solution and moles of solute:

$$Moles\,HNO_3 = (2.0\,Lsoln) \bigg(\frac{0.200\,mol\,HNO_3}{1\,Lsoln}\bigg) = 0.40\,mol\,HNO_3$$

To illustrate the conversion of moles to volume, let's calculate the volume of 0.30 *M* HNO₃ solution required to supply 2.0 mol of HNO₃:

Liters soln =
$$(2.0 \text{ mol HNO}_3) \left[\frac{1 \text{ L soln}}{0.30 \text{ mol HNO}_3} \right] = 6.7 \text{ L soln}$$

In this case we must use the reciprocal of molarity in the conversion:

Liters = moles
$$\times 1/M$$
 = moles \times liters/mole.

If one of the solutes is a liquid, we can use its density to convert its mass to volume and vice versa. For example, a typical American beer contains 5.0% ethanol (CH_3CH_2OH) by volume in water (along with other components). The density of ethanol is 0.789 g/mL. Therefore, if we wanted to calculate the molarity of ethanol (usually just called "alcohol" in everyday language) in beer, we would first consider 1.00 L of beer.

This 1.00 L of beer contains 0.950 L of water and 0.050 L of ethanol:

$$5\% = 5/100 = 0.050$$

Then we can calculate the moles of ethanol by proper cancellation of units, taking into account the density of ethanol and its molar mass (46.0 g/mol):

$$\text{Moles ethanol} = (0.050 \, \text{L}) \left(\frac{1000 \, \text{m/L}}{\text{L}} \right) \left(\frac{0.789 \, \text{g}}{\text{m/L}} \right) \left(\frac{1 \, \text{mol}}{46.0 \, \text{g}} \right) = 0.858 \, \text{mol}$$

Because there are 0.858 moles of ethanol in 1.00 L of beer, the concentration of ethanol in beer is 0.86 *M* (taking into account significant digits).

SAMPLE EXERCISE 4.13 Using Molarity to Calculate Grams of Solute

How many grams of Na₂SO₄ are required to make 0.350 L of 0.500 M Na₂SO₄?

SOLUTION

Analyze We are given the volume of the solution (0.350 L), its concentration (0.500 M), and the identity of the solute Na_2SO_4 and asked to calculate the number of grams of the solute in the solution.

Plan We can use the definition of molarity (Equation 4.32) to determine the number of moles of solute, and then convert moles to grams using the molar mass of the solute.

$$M_{\text{Na}_2\text{SO}_4} = \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}}$$

Solve Calculating the moles of Na₂SO₄ using the molarity and volume of solution gives

$$\begin{split} M_{\mathrm{Na_2SO_4}} &= \frac{\mathrm{moles\ Na_2SO_4}}{\mathrm{liters\ soln}} \\ \mathrm{Moles\ Na_2SO_4} &= \mathrm{liters\ soln} \times M_{\mathrm{Na_2SO_4}} \\ &= (0.350\ \mathrm{L\ soln}) \bigg(\frac{0.500\ \mathrm{mol\ Na_2SO_4}}{1\ \mathrm{L\ soln}} \bigg) \\ &= 0.175\ \mathrm{mol\ Na_2SO_4} \end{split}$$

Because each mole of Na_2SO_4 has a mass of 142.1 g, the required number of grams of Na_2SO_4 is

Grams
$$Na_2SO_4 = (0.175 \text{ mol-Na}_2SO_4) \left(\frac{142.1 \text{ g } Na_2SO_4}{1 \text{ mol-Na}_2SO_4}\right)$$

= 24.9 g Na_2SO_4

Check The magnitude of the answer, the units, and the number of significant figures are all appropriate.

Practice Exercise 1

What is the concentration of ammonia in a solution made by dissolving 3.75 g of ammonia in 120.0 L of water? (a) $1.84 \times 10^{-3} M$, (b) $3.78 \times 10^{-2} M$, (c) 0.0313 M, (d) 1.84 M, (e) 7.05 M.

Practice Exercise 2

(a) How many grams of Na₂SO₄ are there in 15 mL of 0.50 *M* Na₂SO₄? (b) How many milliliters of 0.50 *M* Na₂SO₄ solution are needed to provide 0.038 mol of this salt?

Dilution

Solutions used routinely in the laboratory are often purchased or prepared in concentrated form (called *stock solutions*). Solutions of lower concentrations can then be obtained by adding water, a process called **dilution**.*

Let's see how we can prepare a dilute solution from a concentrated one. Suppose we want to prepare 250.0 mL (that is, 0.2500 L) of 0.100 M CuSO₄ solution by diluting a 1.00 M CuSO₄ stock solution. The main point to remember is that when solvent is added to a solution, the number of moles of solute remains unchanged:

Moles solute before dilution
$$=$$
 moles solute after dilution [4.33]

Because we know both the volume (250.0 mL) and the concentration (0.100 mol/L) of the dilute solution, we can calculate the number of moles of $CuSO_4$ it contains:

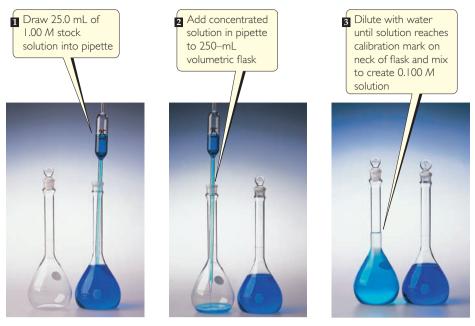

$$\begin{aligned} \text{Moles CuSO}_4 \text{ in dilute soln} &= (0.2500 \text{ Lsoln}) \bigg(\frac{0.100 \text{ mol CuSO}_4}{\text{Lsoln}} \bigg) \\ &= 0.0250 \text{ mol CuSO}_4 \end{aligned}$$

The volume of stock solution needed to provide 0.0250 mol CuSO₄ is therefore:

$$\text{Liters of conc soln} = (0.0250 \, \text{mol CuSO}_4) \left(\frac{1 \, \text{L soln}}{1.00 \, \text{mol CuSO}_4} \right) = 0.0250 \, \text{L}$$

Figure 4.16 shows the dilution carried out in the laboratory. Notice that the diluted solution is less intensely colored than the concentrated one.

^{*}In diluting a concentrated acid or base, the acid or base should be added to water and then further diluted by adding more water. Adding water directly to concentrated acid or base can cause spattering because of the intense heat generated.

▲ Figure 4.16 Preparing 250.0 mL of 0.100 M CuSO₄ by dilution of 1.00 M CuSO₄

Give It Some Thought

How is the molarity of a 0.50 *M* KBr solution changed when water is added to double its volume?

In laboratory situations, calculations of this sort are often made with an equation derived by remembering that the number of moles of solute is the same in both the concentrated and dilute solutions and that moles = molarity \times liters:

Moles solute in conc soln = moles solute in dilute soln

$$M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}}$$
 [4.34]

Although we derived Equation 4.34 in terms of liters, any volume unit can be used as long as it is used on both sides of the equation. For example, in the calculation we did for the ${\rm CuSO_4}$ solution, we have

$$(1.00 M)(V_{\text{conc}}) = (0.100 M)(250.0 \text{ mL})$$

Solving for V_{conc} gives $V_{\text{conc}} = 25.0 \text{ mL}$ as before.

SAMPLE EXERCISE 4.14 Preparing a Solution by Dilution

How many milliliters of 3.0 M H₂SO₄ are needed to make 450 mL of 0.10 M H₂SO₄?

SOLUTION

Analyze We need to dilute a concentrated solution. We are given the molarity of a more concentrated solution $(3.0 \, M)$ and the volume and molarity of a more dilute one containing the same solute $(450 \, \text{mL})$ of $0.10 \, M$ solution). We must calculate the volume of the concentrated solution needed to prepare the dilute solution.

Plan We can calculate the number of moles of solute, H_2SO_4 , in the dilute solution and then calculate the volume of the concentrated solution needed to supply this amount of solute. Alternatively, we can directly apply Equation 4.34. Let's compare the two methods.

Solve Calculating the moles of H₂SO₄ in the dilute solution:

$$\begin{aligned} \text{Moles H_2SO}_4 \text{ in dilute solution} &= (0.450 \text{ L-soln}) \bigg(\frac{0.10 \text{ mol } H_2 \text{SO}_4}{1 \text{ L-soln}} \bigg) \\ &= 0.045 \text{ mol } H_2 \text{SO}_4 \end{aligned}$$

Calculating the volume of the concentrated solution that contains $0.045 \text{ mol } H_2SO_4$:

$$L \ conc \ soln \ = \ (0.045 \ mol \ H_2 SO_4) \bigg(\frac{1 \ L \ soln}{3.0 \ mol \ H_2 SO_4} \bigg) \ = \ 0.015 \ L \ soln$$

Converting liters to milliliters gives 15 mL.

If we apply Equation 4.34, we get the same result:

$$(3.0 M)(V_{\text{conc}}) = (0.10 M)(450 \text{ mL})$$

 $(V_{\text{conc}}) = \frac{(0.10 M)(450 \text{ mL})}{3.0 M} = 15 \text{ mL}$

Either way, we see that if we start with 15 mL of $3.0~M~H_2SO_4$ and dilute it to a total volume of 450 mL, the desired 0.10~M solution will be obtained.

Check The calculated volume seems reasonable because a small volume of concentrated solution is used to prepare a large volume of dilute solution.

Comment The first approach can also be used to find the final concentration when two solutions of different concentrations are mixed, whereas the second approach, using Equation 4.34,

can be used only for diluting a concentrated solution with pure solvent.

Practice Exercise 1

What volume of a 1.00 M stock solution of glucose must be used to make 500.0 mL of a 1.75 \times 10⁻² M glucose solution in water? (a) 1.75 mL, (b) 8.75 mL, (c) 48.6 mL, (d) 57.1 mL, (e) 28,570 mL.

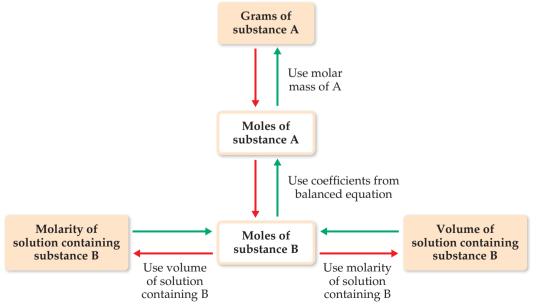

Practice Exercise 2

(a) What volume of 2.50 M lead(II) nitrate solution contains 0.0500 mol of Pb²⁺? (b) How many milliliters of 5.0 M K₂Cr₂O₇ solution must be diluted to prepare 250 mL of 0.10 M solution? (c) If 10.0 mL of a 10.0 M stock solution of NaOH is diluted to 250 mL, what is the concentration of the resulting stock solution?

4.6 | Solution Stoichiometry and Chemical Analysis

In Chapter 3 we learned that given the chemical equation for a reaction and the amount of one reactant consumed in the reaction, you can calculate the quantities of other reactants and products. In this section we extend this concept to reactions involving solutions.

Recall that the coefficients in a balanced equation give the relative number of moles of reactants and products. ∞ (Section 3.6) To use this information, we must convert the masses of substances involved in a reaction into moles. When dealing with pure substances, as we did in Chapter 3, we use molar mass to convert between grams and moles of the substances. This conversion is not valid when working with a solution because both solute and solvent contribute to its mass. However, if we know the solute concentration, we can use molarity and volume to determine the number of moles (moles solute $= M \times V$). \blacktriangledown Figure 4.17 summarizes this approach to using stoichiometry for the reaction between a pure substance and a solution.

▲ Figure 4.17 Procedure for solving stoichiometry problems involving reactions between a pure substance A and a solution containing a known concentration of substance B. Starting from a known mass of substance A, we follow the red arrows to determine either the volume of the solution containing B (if the molarity of B is known) or the molarity of the solution containing B (if the volume of B is known). Starting from either a known volume or known molarity of the solution containing B, we follow the green arrows to determine the mass of substance A.

SAMPLE EXERCISE 4.15 Using Mass Relations in a Neutralization Reaction

How many grams of Ca(OH)₂ are needed to neutralize 25.0 mL of 0.100 M HNO₃?

SOLUTION

Analyze The reactants are an acid, HNO_3 , and a base, $Ca(OH)_2$. The volume and molarity of HNO_3 are given, and we are asked how many grams of $Ca(OH)_2$ are needed to neutralize this quantity of HNO_3 .

Plan Following the steps outlined by the green arrows in Figure 4.17, we use the molarity and volume of the HNO_3 solution (substance B in Figure 4.17) to calculate the number of moles of HNO_3 . We then use the balanced equation to relate moles of HNO_3 to moles of $Ca(OH)_2$ (substance A). Finally, we use the molar mass to convert moles to grams of $Ca(OH)_2$:

$$V_{\text{HNO}_3} \times M_{\text{HNO}_3} \Longrightarrow \text{mol HNO}_3 \Longrightarrow \text{mol Ca(OH)}_2 \Longrightarrow \text{g Ca(OH)}_2$$

Solve The product of the molar concentration of a solution and its volume in liters gives the number of moles of solute:

Moles HNO₃ =
$$V_{\text{HNO}_3} \times M_{\text{HNO}_3} = (0.0250 \text{ E}) \left(\frac{0.100 \text{ mol HNO}_3}{\text{E}} \right)$$

= 2.50 × 10⁻³ mol HNO₃

Because this is a neutralization reaction, HNO_3 and $Ca(OH)_2$ react to form H_2O and the salt containing Ca^{2+} and NO_3^{-} :

$$2 \text{ HNO}_3(aq) + \text{Ca}(\text{OH})_2(s) \longrightarrow 2 \text{ H}_2\text{O}(l) + \text{Ca}(\text{NO}_3)_2(aq)$$

Thus, 2 mol HNO₃ \simeq mol Ca(OH)₂. Therefore, Grams Ca(OH)₂ = $(2.50 \times 10^{-3} \text{ mol-HNO}_3)$

$$\times \left(\frac{1 \operatorname{mol-Ca(OH)_2}}{2 \operatorname{mol-HNO_3}}\right) \left(\frac{74.1 \operatorname{g Ca(OH)_2}}{1 \operatorname{mol-Ca(OH)_2}}\right)$$
= 0.0926 g Ca(OH)₂

Check The answer is reasonable because a small volume of dilute acid requires only a small amount of base to neutralize it.

Practice Exercise 1

How many milligrams of sodium sulfide are needed to completely react with 25.00 mL of a 0.0100 *M* aqueous solution of cadmium nitrate, to form a precipitate of CdS(s)? (a) 13.8 mg, (b) 19.5 mg, (c) 23.5 mg, (d) 32.1 mg, (e) 39.0 mg.

Practice Exercise 2

(a) How many grams of NaOH are needed to neutralize 20.0 mL of $0.150 \, M \, H_2 SO_4$ solution? (b) How many liters of $0.500 \, M \, HCl(aq)$ are needed to react completely with $0.100 \, mol$ of $Pb(NO_3)_2(aq)$, forming a precipitate of $PbCl_2(s)$?

Titrations

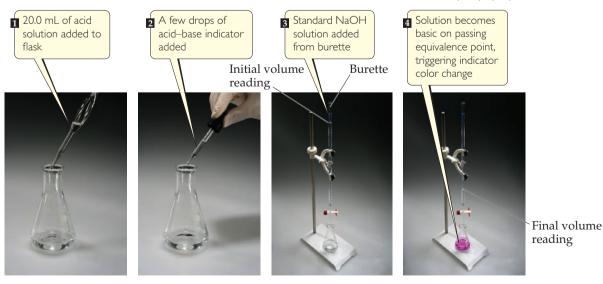

To determine the concentration of a particular solute in a solution, chemists often carry out a **titration**, which involves combining a solution where the solute concentration is not known with a reagent solution of known concentration, called a **standard solution**. Just enough standard solution is added to completely react with the solute in the solution of unknown concentration. The point at which stoichiometrically equivalent quantities are brought together is known as the **equivalence point**.

Titrations can be conducted using neutralization, precipitation, or oxidation-reduction reactions. ▼ Figure 4.18 illustrates a typical neutralization titration, one

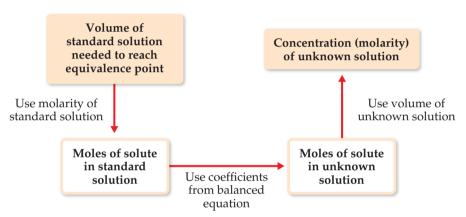

GO FIGURE

How would the volume of standard solution added change if that solution were $Ba(OH)_2(aq)$ instead of NaOH(aq)?

▲ Figure 4.18 Procedure for titrating an acid against a standard solution of NaOH. The acid—base indicator, phenolphthalein, is colorless in acidic solution but takes on a pink color in basic solution.

between an HCl solution of unknown concentration and a standard NaOH solution. To determine the HCl concentration, we first add a specific volume of the HCl solution, 20.0 mL in this example, to a flask. Next we add a few drops of an acid-base indicator. The acid-base indicator is a dye that changes color on passing the equivalence point.* For example, the dye phenolphthalein is colorless in acidic solution but pink in basic solution. The standard solution is then slowly added until the solution turns pink, telling us that the neutralization reaction between HCl and NaOH is complete. The standard solution is added from a *burette* so that we can accurately determine the added volume of NaOH solution. Knowing the volumes of both solutions and the concentration of the standard solution, we can calculate the concentration of the unknown solution as diagrammed in Figure 4.19.

▲ Figure 4.19 Procedure for determining the concentration of a solution from titration with a standard solution.

SAMPLE EXERCISE 4.16 Determining Solution Concentration by an Acid-Base Titration

One commercial method used to peel potatoes is to soak them in a NaOH solution for a short time and then remove the potatoes and spray off the peel. The NaOH concentration is normally 3 to 6 M, and the solution must be analyzed periodically. In one such analysis, 45.7 mL of 0.500 M H₂SO₄ is required to neutralize 20.0 mL of NaOH solution. What is the concentration of the NaOH solution?

SOLUTION

Analyze We are given the volume (45.7 mL) and molarity (0.500 M) of an $\rm H_2SO_4$ solution (the standard solution) that reacts completely with 20.0 mL of NaOH solution. We are asked to calculate the molarity of the NaOH solution.

Plan Following the steps given in Figure 4.19, we use the H_2SO_4 volume and molarity to calculate the number of moles of H_2SO_4 . Then we can use this quantity and the balanced equation for the reaction to calculate moles of NaOH. Finally, we can use moles of NaOH and the NaOH volume to calculate NaOH molarity.

Solve The number of moles of H_2SO_4 is the product of the volume and molarity of this solution:

Moles
$$H_2SO_4 = (45.7 \text{ mL soln}) \left(\frac{1 \text{L soln}}{1000 \text{ mL soln}} \right) \left(\frac{0.500 \text{ mol } H_2SO_4}{\text{L soln}} \right)$$

$$= 2.28 \times 10^{-2} \text{ mol } H_2SO_4$$

Acids react with metal hydroxides to form water and a salt. Thus, the balanced equation for the neutralization reaction is

$$H_2SO_4(aq) + 2 NaOH(aq) \longrightarrow 2 H_2O(l) + Na_2SO_4(aq)$$

^{*}More precisely, the color change of an indicator signals the end point of the titration, which if the proper indicator is chosen lies very near the equivalence point. Acid-base titrations are discussed in more detail in Section 17.3.

According to the balanced equation, 1 mol $H_2SO_4 \simeq 2$ mol NaOH. Therefore,

Moles NaOH =
$$(2.28 \times 10^{-2} \text{ mol H}_{\overline{2}}\text{SO}_{\overline{4}}) \left(\frac{2 \text{ mol NaOH}}{1 \text{ mol H}_{\overline{2}}\text{SO}_{\overline{4}}}\right)$$

= $4.56 \times 10^{-2} \text{ mol NaOH}$

Knowing the number of moles of NaOH in 20.0 mL of solution allows us to calculate the molarity of this solution:

$$\begin{split} \text{Molarity NaOH} &= \frac{\text{mol NaOH}}{\text{L soln}} \\ &= \bigg(\frac{4.56 \times 10^{-2} \, \text{mol NaOH}}{20.0 \, \text{mL soln}}\bigg) \bigg(\frac{1000 \, \text{mL soln}}{1 \, \text{L soln}}\bigg) \\ &= 2.28 \, \frac{\text{mol NaOH}}{\text{L soln}} = 2.28 \, M \end{split}$$

Practice Exercise 1

What is the molarity of an HCl solution if 27.3 mL of it neutralizes 134.5 mL of $0.0165 M \text{ Ba}(\text{OH})_2$? (a) 0.0444 M, (b) 0.0813 M, (c) 0.163 M, (d) 0.325 M, (e) 3.35 M.

Practice Exercise 2

What is the molarity of a NaOH solution if 48.0 mL neutralizes 35.0 mL of $0.144 \text{ M H}_2\text{SO}_4$?

SAMPLE EXERCISE 4.17

Determining the Quantity of Solute by Titration

The quantity of Cl^- in a municipal water supply is determined by titrating the sample with Ag^+ . The precipitation reaction taking place during the titration is

$$Ag^{+}(aq) + Cl^{-}(aq) \longrightarrow AgCl(s)$$

The end point in this type of titration is marked by a change in color of a special type of indicator. (a) How many grams of chloride ion are in a sample of the water if 20.2 mL of $0.100 M \text{ Ag}^+$ is needed to react with all the chloride in the sample? (b) If the sample has a mass of 10.0 g, what percentage of Cl^- does it contain?

SOLUTION

Analyze We are given the volume (20.2 mL) and molarity (0.100 M) of a solution of Ag^+ and the chemical equation for reaction of this ion with Cl^- . We are asked to calculate the number of grams of Cl^- in the sample and the mass percentage of Cl^- in the sample.

(a) Plan We can use the procedure outlined by the green arrows in Figure 4.17. We begin by using the volume and molarity of Ag⁺ to calculate the number of moles of Ag⁺ used in the titration. We then use the balanced equation to determine the moles of Cl⁻ in the sample and from that the grams of Cl⁻.

Solve

$$\begin{split} \text{Moles Ag}^+ &= (20.2 \text{ mL-soln}) \bigg(\frac{1 \text{ L-soln}}{1000 \text{ mL-soln}} \bigg) \bigg(\frac{0.100 \text{ mol Ag}^+}{\text{L-soln}} \bigg) \\ &= 2.02 \times 10^{-3} \text{ mol Ag}^+ \end{split}$$

From the balanced equation we see that 1 mol Ag $^+\simeq 1$ mol Cl $^-$. Using this information and the molar mass of Cl, we have

Grams
$$Cl^- = (2.02 \times 10^{-3} \text{ mol-Ag}^+) \left(\frac{1 \text{ mol-Cl}^-}{1 \text{ mol-Ag}^+}\right) \left(\frac{35.5 \text{ g Cl}^-}{\text{mol-Cl}^-}\right)$$

= 7.17 × 10⁻² g Cl⁻

(b) Plan To calculate the percentage of Cl $^-$ in the sample, we compare the number of grams of Cl $^-$ in the sample, 7.17×10^{-2} g, with the original mass of the sample, 10.0 g.

Solve

$$Percent \ Cl^- = \frac{7.17 \, \times \, 10^{-2} \, g}{10.0 \, g} \times \, 100\% \, = \, 0.717\% \ Cl^-$$

Comment Chloride ion is one of the most common ions in water and sewage. Ocean water contains 1.92% Cl^- . Whether water containing Cl^- tastes salty depends on the other ions present. If the only accompanying ions are Na^+ , a salty taste may be detected with as little as 0.03% Cl^- .

Practice Exercise 1

A mysterious white powder is found at a crime scene. A simple chemical analysis concludes that the powder is a mixture of sugar and morphine ($C_{17}H_{19}NO_3$), a weak base similar to ammonia. The crime lab takes 10.00 mg of the mysterious white powder, dissolves it in 100.00 mL water, and titrates it to the equivalence point with 2.84 mL of a standard 0.0100 M HCl solution. What is the percentage of morphine in the white powder? (a) 8.10%, (b) 17.3%, (c) 32.6%, (d) 49.7%, (e) 81.0%.

Practice Exercise 2

A sample of an iron ore is dissolved in acid, and the iron is converted to ${\rm Fe}^{2+}$. The sample is then titrated with 47.20 mL of 0.02240 $M\,{\rm MnO_4}^-$ solution. The oxidation-reduction reaction that occurs during titration is

$$MnO_4^-(aq) + 5 Fe^{2+}(aq) + 8 H^+(aq) \longrightarrow Mn^{2+}(aq) + 5 Fe^{3+}(aq) + 4 H_2O(l)$$

- (a) How many moles of MnO₄ were added to the solution?
- (b) How many moles of Fe^{2+} were in the sample? (c) How many grams of iron were in the sample? (d) If the sample had a mass of 0.8890 g, what is the percentage of iron in the sample?

SAMPLE INTEGRATIVE EXERCISE

Putting Concepts Together

Note: *Integrative exercises require skills from earlier chapters as well as ones from the present chapter.*

A sample of 70.5 mg of potassium phosphate is added to 15.0 mL of 0.050 M silver nitrate, resulting in the formation of a precipitate. (a) Write the molecular equation for the reaction. (b) What is the limiting reactant in the reaction? (c) Calculate the theoretical yield, in grams, of the precipitate that forms.

SOLUTION

(a) Potassium phosphate and silver nitrate are both ionic compounds. Potassium phosphate contains K⁺ and PO₄³⁻ ions, so its chemical formula is K₃PO₄. Silver nitrate contains Ag⁺ and NO₃⁻ ions, so its chemical formula is AgNO₃. Because both reactants are strong electrolytes, the solution contains, K⁺, PO₄³⁻, Ag⁺, and NO₃⁻ ions before the reaction occurs. According to the solubility guidelines in Table 4.1, Ag⁺ and PO₄³⁻ form an insoluble compound, so Ag₃PO₄ will precipitate from the solution. In contrast, K⁺ and NO₃⁻ will remain in solution because KNO₃ is water soluble. Thus, the balanced molecular equation for the reaction is

$$K_3PO_4(aq) + 3 AgNO_3(aq) \longrightarrow Ag_3PO_4(s) + 3 KNO_3(aq)$$

(b) To determine the limiting reactant, we must examine the number of moles of each reactant. \bigcirc (Section 3.7) The number of moles of K_3PO_4 is calculated from the mass of the sample using the molar mass as a conversion factor. \bigcirc (Section 3.4) The molar mass of K_3PO_4 is 3(39.1) + 31.0 + 4(16.0) = 212.3 g/mol. Converting milligrams to grams and then to moles, we have

$$(70.5 \text{ mg } \text{K}_{3} \text{PO}_{4}) \left(\frac{10^{-3} \text{ g } \text{K}_{3} \text{PO}_{4}}{1 \text{ mg } \text{K}_{3} \text{PO}_{4}} \right) \left(\frac{1 \text{ mol } \text{K}_{3} \text{PO}_{4}}{212.3 \text{ g } \text{K}_{3} \text{PO}_{4}} \right)$$

$$= 3.32 \times 10^{-4} \text{ mol } \text{K}_{3} \text{PO}_{4}$$

We determine the number of moles of AgNO₃ from the volume and molarity of the solution. (Section 4.5) Converting milliliters to liters and then to moles, we have

$$\begin{split} (15.0 \text{ mL}) & \bigg(\frac{10^{-3} \text{L}}{1 \text{ mL}}\bigg) \bigg(\frac{0.050 \text{ mol AgNO}_3}{\text{L}}\bigg) \\ & = 7.5 \times 10^{-4} \text{mol AgNO}_3 \end{split}$$

Comparing the amounts of the two reactants, we find that there are $(7.5 \times 10^{-4})/(3.32 \times 10^{-4}) = 2.3$ times as many moles of AgNO₃ as there are moles of K₃PO₄. According to the balanced equation, however, 1 mol K₃PO₄ requires 3 mol AgNO₃. Thus, there is insufficient AgNO₃ to consume the K₃PO₄, and AgNO₃ is the limiting reactant.

(c) The precipitate is Ag_3PO_4 , whose molar mass is 3(107.9) + 31.0 + 4(16.0) = 418.7 g/mol. To calculate the number of grams of Ag_3PO_4 that could be produced in this reaction (the theoretical yield), we use the number of moles of the limiting reactant, converting mol $AgNO_3 \Rightarrow mol\ Ag_3PO_4 \Rightarrow g\ Ag_3PO_4$. We use the coefficients in the balanced equation to convert moles of $AgNO_3$ to moles Ag_3PO_4 , and we use the molar mass of Ag_3PO_4 to convert the number of moles of this substance to grams.

$$(7.5 \times 10^{-4} \, \text{mol AgNO}_{3}) \left(\frac{1 \, \text{mol Ag}_{3} \text{PO}_{4}}{3 \, \text{mol AgNO}_{3}}\right) \left(\frac{418.7 \, \text{g Ag}_{3} \text{PO}_{4}}{1 \, \text{mol Ag}_{3} \text{PO}_{4}}\right) \\ = 0.10 \, \text{g Ag}_{3} \text{PO}_{4}$$

The answer has only two significant figures because the quantity of $AgNO_3$ is given to only two significant figures.

Chapter Summary and Key Terms

GENERAL PROPERTIES OF AQUEOUS SOLUTIONS (INTRODUC-TION AND SECTION 4.1) Solutions in which water is the dissolving medium are called **aqueous solutions**. The component of the solution that is present in the greatest quantity is the **solvent**. The other components are **solutes**.

Any substance whose aqueous solution contains ions is called an electrolyte. Any substance that forms a solution containing no ions is a nonelectrolyte. Electrolytes that are present in solution entirely as ions are strong electrolytes, whereas those that are present partly as ions and partly as molecules are weak electrolytes. Ionic compounds dissociate into ions when they dissolve, and they are strong electrolytes. The solubility of ionic substances is made possible by solvation, the interaction of ions with polar solvent molecules. Most molecular compounds are nonelectrolytes, although some are weak electrolytes, and a few are strong electrolytes. When representing the ionization of a weak electrolyte in solution, half-arrows in both directions are used, indicating that the forward and reverse reactions can achieve a chemical balance called a chemical equilibrium.

PRECIPITATION REACTIONS (SECTION 4.2) Precipitation reactions are those in which an insoluble product, called a **precipitate**, forms. Solubility guidelines help determine whether an ionic compound will be soluble in water. (The **solubility** of a substance is the amount that dissolves in a given quantity of solvent.) Reactions such as precipitation

reactions, in which cations and anions appear to exchange partners, are called exchange reactions, or metathesis reactions.

Chemical equations can be written to show whether dissolved substances are present in solution predominantly as ions or molecules. When the complete chemical formulas of all reactants and products are used, the equation is called a molecular equation. A complete ionic equation shows all dissolved strong electrolytes as their component ions. In a net ionic equation, those ions that go through the reaction unchanged (spectator ions) are omitted.

ACIDS, BASES, AND NEUTRALIZATION REACTIONS (SECTION 4.3)

Acids and bases are important electrolytes. Acids are proton donors; they increase the concentration of $H^+(aq)$ in aqueous solutions to which they are added. Bases are proton acceptors; they increase the concentration of $OH^-(aq)$ in aqueous solutions. Those acids and bases that are strong electrolytes are called strong acids and strong bases, respectively. Those that are weak electrolytes are weak acids and weak bases. When solutions of acids and bases are mixed, a neutralization reaction occurs. The neutralization reaction between an acid and a metal hydroxide produces water and a salt. Gases can also be formed as a result of neutralization reactions. The reaction of a sulfide with an acid forms $H_2S(g)$; the reaction between a carbonate and an acid forms $CO_2(g)$.

OXIDATION-REDUCTION REACTIONS (SECTION 4.4) Oxidation is the loss of electrons by a substance, whereas **reduction** is the gain of electrons by a substance. **Oxidation numbers** keep track of electrons during chemical reactions and are assigned to atoms using specific rules. The oxidation of an element results in an increase in its oxidation number, whereas reduction is accompanied by a decrease in oxidation number. Oxidation is always accompanied by reduction, giving **oxidation-reduction**, or **redox. reactions**.

Many metals are oxidized by O_2 , acids, and salts. The redox reactions between metals and acids as well as those between metals and salts are called **displacement reactions**. The products of these displacement reactions are always an element (H_2 or a metal) and a salt. Comparing such reactions allows us to rank metals according to their ease of oxidation. A list of metals arranged in order of decreasing ease of oxidation is called an **activity series**. Any metal on the list can be oxidized by ions of metals (or H^+) below it in the series.

CONCENTRATIONS OF SOLUTIONS (SECTION 4.5) The **concentration** of a solution expresses the amount of a solute dissolved in the solution. One of the common ways to express the concentration of a solute

is in terms of molarity. The **molarity** of a solution is the number of moles of solute per liter of solution. Molarity makes it possible to interconvert solution volume and number of moles of solute. If the solute is a liquid, its density can be used in molarity calculations to convert between mass, volume, and moles. Solutions of known molarity can be formed either by weighing out the solute and diluting it to a known volume or by the **dilution** of a more concentrated solution of known concentration (a stock solution). Adding solvent to the solution (the process of dilution) decreases the concentration of the solute without changing the number of moles of solute in the solution ($M_{\rm conc} \times V_{\rm conc} = M_{\rm dil} \times V_{\rm dil}$).

SOLUTION STOICHIOMETRY AND CHEMICAL ANALYSIS (SECTION 4.6) In the process called titration, we combine a solution of known concentration (a standard solution) with a solution of unknown concentration to determine the unknown concentration or the quantity of solute in the unknown. The point in the titration at which stoichiometrically equivalent quantities of reactants are brought together is called the equivalence point. An indicator can be used to show the end point of the titration, which coincides closely with the equivalence point.

Learning Outcomes After studying this chapter, you should be able to:

- Identify compounds as acids or bases, and as strong, weak, or nonelectrolytes. (Sections 4.1 and 4.3)
- Recognize reactions by type and be able to predict the products of simple acid—base, precipitation, and redox reactions. (Sections 4.2–4.4)
- Be able to calculate molarity and use it to convert between moles of a substance in solution and volume of the solution. (Section 4.5)
- Describe how to carry out a dilution to achieve a desired solution concentration. (Section 4.5)
- Describe how to perform and interpret the results of a titration. (Section 4.6)

Key Equations

• Molarity =
$$\frac{\text{moles solute}}{\text{volume of solution in liters}}$$
 [4..32]

Molarity is the most commonly used unit of concentration in chemistry.

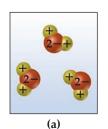

•
$$M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}}$$
 [4.34]

When adding solvent to a concentrated solution to make a dilute solution, molarities and volumes of both concentrated and dilute solutions can be calculated if three of the quantities are known.

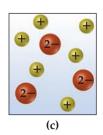

Exercises

Visualizing Concepts

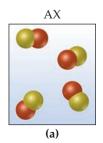

4.1 Which of the following schematic drawings best describes a solution of Li₂SO₄ in water (water molecules not shown for simplicity)? [Section 4.1]

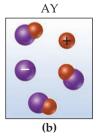

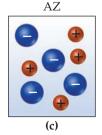

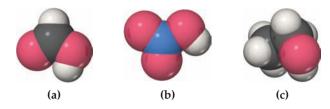

4.2 Aqueous solutions of three different substances, AX, AY, and AZ, are represented by the three accompanying diagrams. Identify each substance as a strong electrolyte, a weak electrolyte, or a nonelectrolyte. [Section 4.1]

4.3 Use the molecular representations shown here to classify each compound as a nonelectrolyte, a weak electrolyte, or a strong electrolyte (see Figure 4.6 for element color scheme). [Sections 4.1 and 4.3]

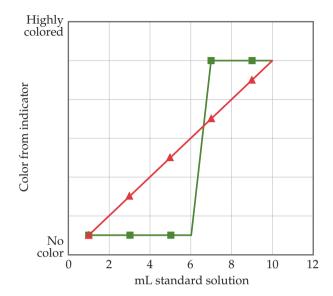

- **4.4** The concept of chemical equilibrium is very important. Which one of the following statements is the most correct way to think about equilibrium?
 - (a) If a system is at equilibrium, nothing is happening.
 - (b) If a system is at equilibrium, the rate of the forward reaction is equal to the rate of the back reaction.
 - (c) If a system is at equilibrium, the product concentration is changing over time. [Section 4.1]
- 4.5 You are presented with a white solid and told that due to careless labeling it is not clear if the substance is barium chloride, lead chloride, or zinc chloride. When you transfer the solid to a beaker and add water, the solid dissolves to give a clear solution. Next a $Na_2SO_4(aq)$ solution is added and a white precipitate forms. What is the identity of the unknown white solid? [Section 4.2]

- **4.6** We have seen that ions in aqueous solution are stabilized by the attractions between the ions and the water molecules. Why then do some pairs of ions in solution form precipitates? [Section 4.2]
- 4.7 Which of the following ions will *always* be a spectator ion in a precipitation reaction? (a) Cl⁻, (b) NO₃⁻, (c) NH₄⁺, (d) S²⁻, (e) SO₄²⁻. [Section 4.2]
- **4.8** The labels have fallen off three bottles containing powdered samples of metals; one contains zinc, one lead, and the other platinum. You have three solutions at your disposal: 1 *M* sodium nitrate, 1 *M* nitric acid, and 1 *M* nickel nitrate. How could you use these solutions to determine the identities of each metal powder? [Section 4.4]
- **4.9** Explain how a redox reaction involves electrons in the same way that a neutralization reaction involves protons. [Sections 4.3 and 4.4]
- **4.10** If you want to double the concentration of a solution, how could you do it? [Section 4.5]

4.11 Which data set, of the two graphed here, would you expect to observe from a titration like that shown in Figure 4.18? [Section 4.6]

4.12 You are titrating an acidic solution with a basic one, and just realized you forgot to add the indicator that tells you when the equivalence point is reached. In this titration, the indicator turns blue at the equivalence point from an initially colorless solution. You quickly grab a bottle of indicator and throw some into your titration beaker, and the whole solution turns dark blue. What do you do now? [Section 4.6]

General Properties of Aqueous Solutions (Section 4.1)

- **4.13** State whether each of the statements below is true or false. Justify your answer in each case.
 - (a) Electrolyte solutions conduct electricity because electrons are moving through the solution.
 - **(b)** If you add a nonelectrolyte to an aqueous solution that already contains an electrolyte, the electrical conductivity will not change.
- **4.14** State whether each of the statements below is true or false. Justify your answer in each case.
 - (a) When methanol, CH₃OH, is dissolved in water, a conducting solution results.
 - (b) When acetic acid, CH₃COOH, dissolves in water, the solution is weakly conducting and acidic in nature.
- **4.15** We have learned in this chapter that many ionic solids dissolve in water as strong electrolytes; that is, as separated ions in solution. Which statement is most correct about this process? (a) Water is a strong acid and therefore is good at

- dissolving ionic solids. (b) Water is good at solvating ions because the hydrogen and oxygen atoms in water molecules bear partial charges. (c) The hydrogen and oxygen bonds of water are easily broken by ionic solids.
- 4.16 Would you expect that anions would be physically closer to the oxygen or to the hydrogens of water molecules that surround it in solution?
- 4.17 Specify what ions are present in solution upon dissolving each of the following substances in water: (a) FeCl₂, (b) HNO₃,
 (c) (NH₄)₂SO₄, (d) Ca(OH)₂.
- 4.18 Specify what ions are present upon dissolving each of the following substances in water: (a) MgI₂, (b) K₂CO₃, (c) HClO₄, (d) NaCH₃COO.
- **4.19** Formic acid, HCOOH, is a weak electrolyte. What solutes are present in an aqueous solution of this compound? Write the chemical equation for the ionization of HCOOH.
- **4.20** Acetone, CH₃COCH₃, is a nonelectrolyte; hypochlorous acid, HClO, is a weak electrolyte; and ammonium chloride, NH₄Cl, is a strong electrolyte. (a) What are the solutes present in aqueous solutions of each compound? (b) If 0.1 mol of each compound is dissolved in solution, which one contains 0.2 mol of solute particles, which contains 0.1 mol of solute particles, and which contains somewhere between 0.1 and 0.2 mol of solute particles?

Precipitation Reactions (Section 4.2)

- 4.21 Using solubility guidelines, predict whether each of the following compounds is soluble or insoluble in water: (a) MgBr₂,
 (b) PbI₂, (c) (NH₄)₂CO₃, (d) Sr(OH)₂, (e) ZnSO₄.
- **4.22** Predict whether each of the following compounds is soluble in water: (a) AgI, (b) Na₂CO₃, (c) BaCl₂, (d) Al(OH)₃, (e) Zn(CH₃COO)₂.
- **4.23** Will precipitation occur when the following solutions are mixed? If so, write a balanced chemical equation for the reaction. (a) Na₂CO₃ and AgNO₃, (b) NaNO₃ and NiSO₄, (c) FeSO₄ and Pb(NO₃)₂.
- 4.24 Identify the precipitate (if any) that forms when the following solutions are mixed, and write a balanced equation for each reaction. (a) NaCH₃COO and HCl, (b) KOH and Cu(NO₃)₂, (c) Na₂S and CdSO₄.
- **4.25** Which ions remain in solution, unreacted, after each of the following pairs of solutions is mixed?
 - (a) potassium carbonate and magnesium sulfate
 - (b) lead nitrate and lithium sulfide
 - (c) ammonium phosphate and calcium chloride
- **4.26** Write balanced net ionic equations for the reactions that occur in each of the following cases. Identify the spectator ion or ions in each reaction.
 - (a) $Cr_2(SO_4)_3(aq) + (NH_4)_2CO_3(aq) \longrightarrow$
 - **(b)** Ba(NO₃)₂(aq) + K₂SO₄(aq) \longrightarrow
 - (c) $Fe(NO_3)_2(aq) + KOH(aq) \longrightarrow$
- **4.27** Separate samples of a solution of an unknown salt are treated with dilute solutions of HBr, H₂SO₄, and NaOH. A precipitate forms in all three cases. Which of the following cations could be present in the unknown salt solution: K⁺, Pb²⁺, Ba²⁺?
- **4.28** Separate samples of a solution of an unknown ionic compound are treated with dilute AgNO₃, Pb(NO₃)₂, and BaCl₂.

- Precipitates form in all three cases. Which of the following could be the anion of the unknown salt: Br⁻, CO₃²⁻, NO₃⁻?
- 4.29 You know that an unlabeled bottle contains an aqueous solution of one of the following: AgNO₃, CaCl₂, or Al₂(SO₄)₃. A friend suggests that you test a portion of the solution with Ba(NO₃)₂ and then with NaCl solutions. According to your friend's logic, which of these chemical reactions could occur, thus helping you identify the solution in the bottle? (a) Barium sulfate could precipitate. (b) Silver chloride could precipitate. (c) Silver sulfate could precipitate. (d) More than one, but not all, of the reactions described in answers a–c could occur. (e) All three reactions described in answers a–c could occur.
- 4.30 Three solutions are mixed together to form a single solution; in the final solution, there are 0.2 mol Pb(CH₃COO)₂, 0.1 mol Na₂S, and 0.1 mol CaCl₂ present. What solid(s) will precipitate?

Acids, Bases, and Neutralization Reactions (Section 4.3)

- **4.31** Which of the following solutions is the most acidic? (a) 0.2 *M* LiOH, (b) 0.2 *M* HI, (c) 1.0 *M* methyl alcohol (CH₃OH).
- **4.32** Which of the following solutions is the most basic? (a) 0.6 M NH₃, (b) 0.150 M KOH, (c) 0.100 M Ba(OH)₂.
- **4.33** State whether each of the following statements is true or false. Justify your answer in each case.
 - (a) Sulfuric acid is a monoprotic acid.
 - (b) HCl is a weak acid.
 - (c) Methanol is a base.
- **4.34** State whether each of the following statements is true or false. Justify your answer in each case.
 - (a) NH₃ contains no OH⁻ ions, and yet its aqueous solutions are basic.
 - (b) HF is a strong acid.
 - (c) Although sulfuric acid is a strong electrolyte, an aqueous solution of $\rm H_2SO_4$ contains more $\rm HSO_4^-$ ions than $\rm SO_4^{2-}$ ions.
- **4.35** Label each of the following substances as an acid, base, salt, or none of the above. Indicate whether the substance exists in aqueous solution entirely in molecular form, entirely as ions, or as a mixture of molecules and ions. (**a**) HF, (**b**) acetonitrile, CH₃CN, (**c**) NaClO₄, (**d**) Ba(OH)₂.
- 4.36 An aqueous solution of an unknown solute is tested with litmus paper and found to be acidic. The solution is weakly conducting compared with a solution of NaCl of the same concentration. Which of the following substances could the unknown be: KOH, NH₃, HNO₃, KClO₂, H₃PO₃, CH₃COCH₃ (acetone)?
- 4.37 Classify each of the following substances as a nonelectrolyte, weak electrolyte, or strong electrolyte in water: (a) H₂SO₃,
 (b) C₂H₅OH (ethanol), (c) NH₃, (d) KClO₃, (e) Cu(NO₃)₂.
- 4.38 Classify each of the following aqueous solutions as a non-electrolyte, weak electrolyte, or strong electrolyte: (a) LiClO₄,
 (b) HClO, (c) CH₃CH₂CH₂OH (propanol), (d) HClO₃,
 (e) CuSO₄, (f) C₁₂H₂₂O₁₁ (sucrose).
- **4.39** Complete and balance the following molecular equations, and then write the net ionic equation for each:
 - (a) $HBr(aq) + Ca(OH)_2(aq) \longrightarrow$
 - **(b)** $Cu(OH)_2(s) + HClO_4(aq) \longrightarrow$
 - (c) $Al(OH)_3(s) + HNO_3(aq) \longrightarrow$

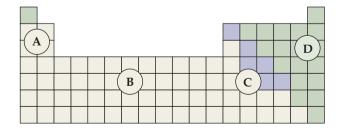

- **4.40** Write the balanced molecular and net ionic equations for each of the following neutralization reactions:
 - (a) Aqueous acetic acid is neutralized by aqueous barium hydroxide.
 - (b) Solid chromium(III) hydroxide reacts with nitrous acid.
 - (c) Aqueous nitric acid and aqueous ammonia react.
- 4.41 Write balanced molecular and net ionic equations for the following reactions, and identify the gas formed in each:(a) solid cadmium sulfide reacts with an aqueous solution of sulfuric acid;(b) solid magnesium carbonate reacts with an aqueous solution of perchloric acid.
- **4.42** Because the oxide ion is basic, metal oxides react readily with acids. (a) Write the net ionic equation for the following reaction:

$$FeO(s) + 2 HClO_4(aq) \longrightarrow Fe(ClO_4)_2(aq) + H_2O(l)$$

- (**b**) Based on the equation in part (a), write the net ionic equation for the reaction that occurs between NiO(*s*) and an aqueous solution of nitric acid.
- 4.43 Magnesium carbonate, magnesium oxide, and magnesium hydroxide are all white solids that react with acidic solutions. (a) Write a balanced molecular equation and a net ionic equation for the reaction that occurs when each substance reacts with a hydrochloric acid solution. (b) By observing the reactions in part (a), how could you distinguish any of the three magnesium substances from the other two?
- 4.44 As K₂O dissolves in water, the oxide ion reacts with water molecules to form hydroxide ions. (a) Write the molecular and net ionic equations for this reaction. (b) Based on the definitions of acid and base, what ion is the base in this reaction?(c) What is the acid in the reaction? (d) What is the spectator ion in the reaction?

Oxidation-Reduction Reactions (Section 4.4)

- **4.45** True or false:
 - (a) If a substance is oxidized, it is gaining electrons.
 - (b) If an ion is oxidized, its oxidation number increases.
- 4.46 True or false:
 - (a) Oxidation can occur without oxygen.
 - (b) Oxidation can occur without reduction.
- **4.47** (a) Which region of the periodic table shown here contains elements that are easiest to oxidize? (b) Which region contains the least readily oxidized elements?

- 4.48 Determine the oxidation number of sulfur in each of the following substances: (a) barium sulfate, BaSO₄, (b) sulfurous acid, H₂SO₃, (c) strontium sulfide, SrS, (d) hydrogen sulfide, H₂S. (e) Locate sulfur in the periodic table in Exercise 4.47; what region is it in? (f) Which region(s) of the period table contains elements that can adopt both positive and negative oxidation numbers?
- **4.49** Determine the oxidation number for the indicated element in each of the following substances: (a) S in SO₂, (b) C in COCl₂, (c) Mn in KMnO₄, (d) Br in HBrO, (e) P in PF₃, (f) O in K₂O₂.

- **4.50** Determine the oxidation number for the indicated element in each of the following compounds: (a) Co in LiCoO₂, (b) Al in NaAlH₄, (c) C in CH₃OH (methanol), (d) N in GaN, (e) Cl in HClO₂, (f) Cr in BaCrO₄.
- **4.51** Which element is oxidized and which is reduced in the following reactions?

(a)
$$N_2(g) + 3 H_2(g) \longrightarrow 2 NH_3(g)$$

(b)
$$3 \operatorname{Fe}(NO_3)_2(aq) + 2 \operatorname{Al}(s) \longrightarrow$$

$$3 \text{ Fe}(s) + 2 \text{ Al}(NO_3)_3(aq)$$

(c)
$$Cl_2(aq) + 2 NaI(aq) \longrightarrow I_2(aq) + 2 NaCl(aq)$$

(d)
$$PbS(s) + 4 H_2O_2(aq) \longrightarrow PbSO_4(s) + 4 H_2O(l)$$

4.52 Which of the following are redox reactions? For those that are, indicate which element is oxidized and which is reduced. For those that are not, indicate whether they are precipitation or neutralization reactions.

(a)
$$P_4(s) + 10 \text{ HClO}(aq) + 6 \text{ H}_2\text{O}(l) \longrightarrow 4 \text{ H}_3\text{PO}_4(aq) + 10 \text{ HCl}(aq)$$

- **(b)** $Br_2(l) + 2K(s) \longrightarrow 2KBr(s)$
- (c) $CH_3CH_2OH(l) + 3O_2(g) \longrightarrow 3H_2O(l) + 2CO_2(g)$

(d)
$$ZnCl_2(aq) + 2 NaOH(aq) \longrightarrow Zn(OH)_2(s) +$$

2 NaCl(aq)

- **4.53** Write balanced molecular and net ionic equations for the reactions of (a) manganese with dilute sulfuric acid, (b) chromium with hydrobromic acid, (c) tin with hydrochloric acid, (d) aluminum with formic acid, HCOOH.
- **4.54** Write balanced molecular and net ionic equations for the reactions of (a) hydrochloric acid with nickel, (b) dilute sulfuric acid with iron, (c) hydrobromic acid with magnesium, (d) acetic acid, CH₃COOH, with zinc.
- **4.55** Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, write NR. (a) Iron metal is added to a solution of copper(II) nitrate, (b) zinc metal is added to a solution of magnesium sulfate, (c) hydrobromic acid is added to tin metal, (d) hydrogen gas is bubbled through an aqueous solution of nickel(II) chloride, (e) aluminum metal is added to a solution of cobalt(II) sulfate.
- **4.56** Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, write NR. (a) Nickel metal is added to a solution of copper(II) nitrate, (b) a solution of zinc nitrate is added to a solution of magnesium sulfate, (c) hydrochloric acid is added to gold metal, (d) chromium metal is immersed in an aqueous solution of cobalt(II) chloride, (e) hydrogen gas is bubbled through a solution of silver nitrate.
- 4.57 The metal cadmium tends to form Cd²⁺ ions. The following observations are made: (i) When a strip of zinc metal is placed in CdCl₂(aq), cadmium metal is deposited on the strip. (ii) When a strip of cadmium metal is placed in Ni(NO₃)₂(aq), nickel metal is deposited on the strip. (a) Write net ionic equations to explain each of the preceding observations. (b) Which elements more closely define the position of cadmium in the activity series? (c) What experiments would you need to perform to locate more precisely the position of cadmium in the activity series?
- **4.58** The following reactions (note that the arrows are pointing only one direction) can be used to prepare an activity series for the halogens:

$$Br_2(aq) + 2 NaI(aq) \longrightarrow 2 NaBr(aq) + I_2(aq)$$

 $Cl_2(aq) + 2 NaBr(aq) \longrightarrow 2 NaCl(aq) + Br_2(aq)$

(a) Which elemental halogen would you predict is the most stable, upon mixing with other halides? (b) Predict whether a reaction will occur when elemental chlorine and potassium iodide are mixed. (c) Predict whether a reaction will occur when elemental bromine and lithium chloride are mixed.

Concentrations of Solutions (Section 4.5)

- **4.59** (a) Is the concentration of a solution an intensive or an extensive property? (b) What is the difference between 0.50 mol HCl and 0.50 *M* HCl?
- **4.60** Your lab partner tells you that he has prepared a solution that contains 1.50 moles of NaOH in 1.50 L of aqueous solution, and therefore that the concentration of NaOH is 1.5 *M.* (a) Is he correct? (b) If not, what is the correct concentration?
- **4.61** (a) Calculate the molarity of a solution that contains 0.175 mol ZnCl₂ in exactly 150 mL of solution. (b) How many moles of protons are present in 35.0 mL of a 4.50 *M* solution of nitric acid? (c) How many milliliters of a 6.00 *M* NaOH solution are needed to provide 0.350 mol of NaOH?
- 4.62 (a) Calculate the molarity of a solution made by dissolving 12.5 grams of Na₂CrO₄ in enough water to form exactly 750 mL of solution. (b) How many moles of KBr are present in 150 mL of a 0.112 M solution? (c) How many milliliters of 6.1 M HCl solution are needed to obtain 0.150 mol of HCl?
- **4.63** The average adult human male has a total blood volume of 5.0 L. If the concentration of sodium ion in this average individual is 0.135 *M*, what is the mass of sodium ion circulating in the blood?
- **4.64** A person suffering from hyponatremia has a sodium ion concentration in the blood of 0.118 *M* and a total blood volume of 4.6 L. What mass of sodium chloride would need to be added to the blood to bring the sodium ion concentration up to 0.138 *M*, assuming no change in blood volume?
- **4.65** The concentration of alcohol (CH₃CH₂OH) in blood, called the "blood alcohol concentration" or BAC, is given in units of grams of alcohol per 100 mL of blood. The legal definition of intoxication, in many states of the United States, is that the BAC is 0.08 or higher. What is the concentration of alcohol, in terms of molarity, in blood if the BAC is 0.08?
- **4.66** The average adult male has a total blood volume of 5.0 L. After drinking a few beers, he has a BAC of 0.10 (see Exercise 4.65). What mass of alcohol is circulating in his blood?
- 4.67 (a) How many grams of ethanol, CH₃CH₂OH, should you dissolve in water to make 1.00 L of vodka (which is an aqueous solution that is 6.86 M ethanol)? (b) Using the density of ethanol (0.789 g/mL), calculate the volume of ethanol you need to make 1.00 L of vodka.
- **4.68** One cup of fresh orange juice contains 124 mg of ascorbic acid (vitamin C, $C_6H_8O_6$). Given that one cup = 236.6 mL, calculate the molarity of vitamin C in organic juice.
- 4.69 (a) Which will have the highest concentration of potassium ion: 0.20 M KCl, 0.15 M K₂CrO₄, or 0.080 M K₃PO₄?
 (b) Which will contain the greater number of moles of potassium ion: 30.0 mL of 0.15 M K₂CrO₄ or 25.0 mL of 0.080 M K₃PO₄?
- **4.70** In each of the following pairs, indicate which has the higher concentration of I $^-$ ion: (a) 0.10 M BaI $_2$ or 0.25 M KI solution, (b) 100 mL of 0.10 M KI solution or 200 mL of 0.040 M ZnI $_2$ solution, (c) 3.2 M HI solution or a solution made by dissolving 145 g of NaI in water to make 150 mL of solution.
- **4.71** Indicate the concentration of each ion or molecule present in the following solutions: (a) 0.25 M NaNO₃,

- (**b**) $1.3 \times 10^{-2} M \, \text{MgSO}_4$, (**c**) $0.0150 \, M \, \text{C}_6 \text{H}_{12} \text{O}_6$, (**d**) a mixture of 45.0 mL of 0.272 $M \, \text{NaCl}$ and 65.0 mL of 0.0247 $M \, (\text{NH}_4)_2 \text{CO}_3$. Assume that the volumes are additive.
- 4.72 Indicate the concentration of each ion present in the solution formed by mixing (a) 42.0 mL of 0.170 M NaOH with 37.6 mL of 0.400 M NaOH, (b) 44.0 mL of 0.100 M Na₂SO₄ with 25.0 mL of 0.150 M KCl, (c) 3.60 g KCl in 75.0 mL of 0.250 M CaCl₂ solution. Assume that the volumes are additive.
- **4.73** (a) You have a stock solution of 14.8 *M* NH₃. How many milliliters of this solution should you dilute to make 1000.0 mL of 0.250 *M* NH₃? (b) If you take a 10.0-mL portion of the stock solution and dilute it to a total volume of 0.500 L, what will be the concentration of the final solution?
- 4.74 (a) How many milliliters of a stock solution of 6.0 M HNO₃ would you have to use to prepare 110 mL of 0.500 M HNO₃?
 (b) If you dilute 10.0 mL of the stock solution to a final volume of 0.250 L, what will be the concentration of the diluted solution?
- **4.75** (a) Starting with solid sucrose, $C_{12}H_{22}O_{11}$, describe how you would prepare 250 mL of a 0.250 M sucrose solution. (b) Describe how you would prepare 350.0 mL of 0.100 M $C_{12}H_{22}O_{11}$ starting with 3.00 L of 1.50 M $C_{12}H_{22}O_{11}$.
- **4.76** (a) How many grams of solid silver nitrate would you need to prepare 200.0 mL of a 0.150 *M* AgNO₃ solution? (b) An experiment calls for you to use 100 mL of 0.50 *M* HNO₃ solution. All you have available is a bottle of 3.6 *M* HNO₃. How many milliliters of the 3.6 *M* HNO₃ solution and of water do you need to prepare the desired solution?
- 4.77 Pure acetic acid, known as glacial acetic acid, is a liquid with a density of 1.049 g/mL at 25 °C. Calculate the molarity of a solution of acetic acid made by dissolving 20.00 mL of glacial acetic acid at 25 °C in enough water to make 250.0 mL of solution.
- **4.78** Glycerol, $C_3H_8O_3$, is a substance used extensively in the manufacture of cosmetics, foodstuffs, antifreeze, and plastics. Glycerol is a water-soluble liquid with a density of $1.2656\,\mathrm{g/mL}$ at $15\,^\circ\mathrm{C}$. Calculate the molarity of a solution of glycerol made by dissolving $50.000\,\mathrm{mL}$ glycerol at $15\,^\circ\mathrm{C}$ in enough water to make $250.00\,\mathrm{mL}$ of solution.

Solution Stoichiometry and Chemical Analysis (Section 4.6)

- 4.79 You want to analyze a silver nitrate solution. (a) You could add HCl(aq) to the solution to precipitate out AgCl(s). What volume of a 0.150 M HCl(aq) solution is needed to precipitate the silver ions from 15.0 mL of a 0.200 M AgNO₃ solution? (b) You could add solid KCl to the solution to precipitate out AgCl(s). What mass of KCl is needed to precipitate the silver ions from 15.0 mL of 0.200 M AgNO₃ solution? (c) Given that a 0.150 M HCl(aq) solution costs \$39.95 for 500 mL, and that KCl costs \$10/ton, which analysis procedure is more cost-effective?
- **4.80** You want to analyze a cadmium nitrate solution. What mass of NaOH is needed to precipitate the Cd^{2+} ions from 35.0 mL of 0.500 M Cd(NO₃)₂ solution?
- 4.81 (a) What volume of 0.115 *M* HClO₄ solution is needed to neutralize 50.00 mL of 0.0875 *M* NaOH? (b) What volume of 0.128 *M* HCl is needed to neutralize 2.87 g of Mg(OH)₂? (c) If 25.8 mL of an AgNO₃ solution is needed to precipitate all the Cl⁻ ions in a 785-mg sample of KCl (forming AgCl), what is the molarity of the AgNO₃ solution? (d) If 45.3 mL of a 0.108 *M* HCl solution is needed to neutralize a solution of KOH, how many grams of KOH must be present in the solution?

161

4.83 Some sulfuric acid is spilled on a lab bench. You can neutralize the acid by sprinkling sodium bicarbonate on it and then mopping up the resultant solution. The sodium bicarbonate reacts with sulfuric acid according to:

$$2 \text{ NaHCO}_3(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{Na}_2\text{SO}_4(aq) + 2 \text{H}_2\text{O}(l) + 2 \text{CO}_2(g)$$

Sodium bicarbonate is added until the fizzing due to the formation of $CO_2(g)$ stops. If 27 mL of 6.0 M H₂SO₄ was spilled, what is the minimum mass of NaHCO₃ that must be added to the spill to neutralize the acid?

4.84 The distinctive odor of vinegar is due to acetic acid, CH₃COOH, which reacts with sodium hydroxide according to:

$$CH_3COO(aq) + NaOH(aq) \longrightarrow H_2O(l) + NaCH_3OO(aq)$$

If 3.45 mL of vinegar needs 42.5 mL of 0.115 *M* NaOH to reach the equivalence point in a titration, how many grams of acetic acid are in a 1.00-qt sample of this vinegar?

4.85 A 4.36-g sample of an unknown alkali metal hydroxide is dissolved in 100.0 mL of water. An acid–base indicator is added and the resulting solution is titrated with 2.50 *M* HCl(*aq*) solution. The indicator changes color signaling that the equivalence point has been reached after 17.0 mL of the hydrochloric acid solution has been added. (a) What is the molar mass of

the metal hydroxide? (**b**) What is the identity of the alkali metal cation: Li⁺, Na⁺, K⁺, Rb⁺, or Cs⁺?

4.86 An 8.65-g sample of an unknown group 2A metal hydroxide is dissolved in 85.0 mL of water. An acid-base indicator is added and the resulting solution is titrated with 2.50 *M* HCl(*aq*) solution. The indicator changes color signaling that the equivalence point has been reached after 56.9 mL of the hydrochloric acid solution has been added. (**a**) What is the molar mass of the metal hydroxide? (**b**) What is the identity of the metal cation: Ca²⁺, Sr²⁺, Ba²⁺?

4.87 A solution of 100.0 mL of 0.200 *M* KOH is mixed with a solution of 200.0 mL of 0.150 *M* NiSO₄. (a) Write the balanced chemical equation for the reaction that occurs. (b) What precipitate forms? (c) What is the limiting reactant? (d) How many grams of this precipitate form? (e) What is the concentration of each ion that remains in solution?

4.88 A solution is made by mixing 15.0 g of Sr(OH)₂ and 55.0 mL of 0.200 *M* HNO₃. (a) Write a balanced equation for the reaction that occurs between the solutes. (b) Calculate the concentration of each ion remaining in solution. (c) Is the resultant solution acidic or basic?

4.89 A 0.5895-g sample of impure magnesium hydroxide is dissolved in 100.0 mL of 0.2050 *M* HCl solution. The excess acid then needs 19.85 mL of 0.1020 *M* NaOH for neutralization. Calculate the percentage by mass of magnesium hydroxide in the sample, assuming that it is the only substance reacting with the HCl solution.

4.90 A 1.248-g sample of limestone rock is pulverized and then treated with 30.00 mL of 1.035 *M* HCl solution. The excess acid then requires 11.56 mL of 1.010 *M* NaOH for neutralization. Calculate the percentage by mass of calcium carbonate in the rock, assuming that it is the only substance reacting with the HCl solution.

Additional Exercises

- **4.91** Uranium hexafluoride, UF₆, is processed to produce fuel for nuclear reactors and nuclear weapons. UF₆ is made from the reaction of elemental uranium with ClF₃, which also produces Cl₂ as a by-product.
 - (a) Write the balanced molecular equation for the conversion of U and ClF₃ into UF₆ and Cl₂.
 - (b) Is this a metathesis reaction?
 - (c) Is this a redox reaction?
- **4.92** The accompanying photo shows the reaction between a solution of Cd(NO₃)₂ and one of Na₂S. (a) What is the identity of the precipitate? (b) What ions remain in solution? (c) Write the net ionic equation for the reaction. (d) Is this a redox reaction?

- **4.93** Suppose you have a solution that might contain any or all of the following cations: Ni²⁺, Ag⁺, Sr²⁺, and Mn²⁺. Addition of HCl solution causes a precipitate to form. After filtering off the precipitate, H₂SO₄ solution is added to the resulting solution and another precipitate forms. This is filtered off, and a solution of NaOH is added to the resulting solution. No precipitate is observed. Which ions are present in each of the precipitates? Which of the four ions listed above must be absent from the original solution?
- **4.94** You choose to investigate some of the solubility guidelines for two ions not listed in Table 4.1, the chromate ion (CrO_4^{2-}) and the oxalate ion $(C_2O_4^{2-})$. You are given 0.01 M solutions (A, B, C, D) of four water-soluble salts:

Solution	Solute	Color of Solution
A	Na ₂ CrO ₄	Yellow
В	$(NH_4)_2C_2O_4$	Colorless
С	$AgNO_3$	Colorless
D	CaCl ₂	Colorless

When these solutions are mixed, the following observations are made:

Experiment Number	Solutions Mixed	Result
1	A + B	No precipitate, yellow solution
2	A + C	Red precipitate forms
3	A + D	Yellow precipitate forms
4	B + C	White precipitate forms
5	B + D	White precipitate forms
6	C + D	White precipitate forms

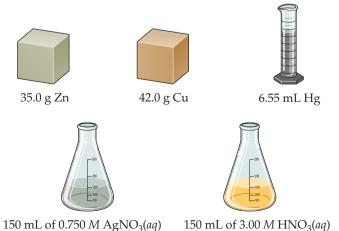

- (a) Write a net ionic equation for the reaction that occurs in each of the experiments. (b) Identify the precipitate formed, if any, in each of the experiments.
- 4.95 Antacids are often used to relieve pain and promote healing in the treatment of mild ulcers. Write balanced net ionic equations for the reactions between the aqueous HCl in the stomach and each of the following substances used in various antacids: (a) Al(OH)₃(s), (b) Mg(OH)₂(s), (c) MgCO₃(s), (d) NaAl(CO₃)(OH)₂(s), (e) CaCO₃(s).
- **4.96** The commercial production of nitric acid involves the following chemical reactions:

$$4 \text{ NH}_3(g) + 5 \text{ O}_2(g) \longrightarrow 4 \text{ NO}(g) + 6 \text{ H}_2\text{O}(g)$$

$$2 \text{ NO}(g) + \text{O}_2(g) \longrightarrow 2 \text{ NO}_2(g)$$

$$3 \text{ NO}_2(g) + \text{H}_2\text{O}(l) \longrightarrow 2 \text{ HNO}_3(aq) + \text{NO}(g)$$

- (a) Which of these reactions are redox reactions? (b) In each redox reaction identify the element undergoing oxidation and the element undergoing reduction. (c) How many grams of ammonia must you start with to make 1000.0 L of a 0.150 M aqueous solution of nitric acid? Assume all the reactions give 100% yield.
- 4.97 Consider the following reagents: zinc, copper, mercury (density 13.6 g/mL), silver nitrate solution, nitric acid solution. (a) Given a 500-mL Erlenmeyer flask and a balloon, can you combine two or more of the foregoing reagents to initiate a chemical reaction that will inflate the balloon? Write a balanced chemical equation to represent this process. What is the identity of the substance that inflates the balloon? (b) What is the theoretical yield of the substance that fills the balloon? (c) Can you combine two or more of the foregoing reagents to initiate a chemical reaction that will produce metallic silver? Write a balanced chemical equation to represent this process. What ions are left behind in solution? (d) What is the theoretical yield of silver?

- **4.98** Lanthanum metal forms cations with a charge of 3+. Consider the following observations about the chemistry of lanthanum: When lanthanum metal is exposed to air, a white solid (compound A) is formed that contains lanthanum and one other element. When lanthanum metal is added to water, gas bubbles are observed and a different white solid (compound B) is formed. Both A and B dissolve in hydrochloric acid to give a clear solution. When either of these solutions is evaporated, a soluble white solid (compound C) remains. If compound C is dissolved in water and sulfuric acid is added, a white precipitate (compound D) forms. (a) Propose identities for the substances A, B, C, and D. (b) Write net ionic equations for all the reactions described. (c) Based on the preceding observations, what can be said about the position of lanthanum in the activity series (Table 4.5)?
- **4.99** A 35.0-mL sample of 1.00 *M* KBr and a 60.0-mL sample of 0.600 *M* KBr are mixed. The solution is then heated to evaporate water until the total volume is 50.0 mL. How many grams of silver nitrate are required to precipitate out silver bromide in the final solution?
- **4.100** Using modern analytical techniques, it is possible to detect sodium ions in concentrations as low as 50 pg/mL. What is this detection limit expressed in (a) molarity of Na⁺, (b) the number of Na⁺ ions per cubic centimeter of solution, (c) the mass of sodium per 1000 L of solution?
- **4.101** Hard water contains Ca²⁺, Mg²⁺, and Fe²⁺, which interfere with the action of soap and leave an insoluble coating on the insides of containers and pipes when heated. Water softeners replace these ions with Na⁺. Keep in mind that charge balance must be maintained. (**a**) If 1500 L of hard water contains 0.020 *M* Ca²⁺ and 0.0040 *M* Mg²⁺, how many moles of Na⁺ is needed to replace these ions? (**b**) If the sodium is added to the water softener in the form of NaCl, how many grams of sodium chloride are needed?
- 4.102 Tartaric acid, H₂C₄H₄O₆, has two acidic hydrogens. The acid is often present in wines and precipitates from solution as the wine ages. A solution containing an unknown concentration of the acid is titrated with NaOH. It requires 24.65 mL of 0.2500 M NaOH solution to titrate both acidic protons in 50.00 mL of the tartaric acid solution. Write a balanced net ionic equation for the neutralization reaction, and calculate the molarity of the tartaric acid solution.
- 4.103 (a) A strontium hydroxide solution is prepared by dissolving 12.50 g of Sr(OH)₂ in water to make 50.00 mL of solution. What is the molarity of this solution? (b) Next the strontium hydroxide solution prepared in part (a) is used to titrate a nitric acid solution of unknown concentration. Write a balanced chemical equation to represent the reaction between strontium hydroxide and nitric acid solutions. (c) If 23.9 mL of the strontium hydroxide solution was needed to neutralize a 37.5 mL aliquot of the nitric acid solution, what is the concentration (molarity) of the acid?
- **4.104** A solid sample of $Zn(OH)_2$ is added to 0.350 L of 0.500 M aqueous HBr. The solution that remains is still acidic. It is then titrated with 0.500 M NaOH solution, and it takes 88.5 mL of the NaOH solution to reach the equivalence point. What mass of $Zn(OH)_2$ was added to the HBr solution?

Integrative Exercises

- **4.105** Suppose you have 5.00 g of powdered magnesium metal, 1.00 L of 2.00 *M* potassium nitrate solution, and 1.00 L of 2.00 *M* silver nitrate solution. (a) Which one of the solutions will react with the magnesium powder? (b) What is the net ionic equation that describes this reaction? (c) What volume of solution is needed to completely react with the magnesium? (d) What is the molarity of the Mg²⁺ ions in the resulting solution?
- **4.106** (a) By titration, 15.0 mL of 0.1008 *M* sodium hydroxide is needed to neutralize a 0.2053-g sample of a weak acid. What is the molar mass of the acid if it is monoprotic? (b) An elemental analysis of the acid indicates that it is composed of 5.89% H, 70.6% C, and 23.5% O by mass. What is its molecular formula?
- 4.107 A 3.455-g sample of a mixture was analyzed for barium ion by adding a small excess of sulfuric acid to an aqueous solution of the sample. The resultant reaction produced a precipitate of barium sulfate, which was collected by filtration, washed, dried, and weighed. If 0.2815 g of barium sulfate was obtained, what was the mass percentage of barium in the sample?
- **4.108** A fertilizer railroad car carrying 34,300 gallons of commercial aqueous ammonia (30% ammonia by mass) tips over and spills. The density of the aqueous ammonia solution is 0.88 g/cm^3 . What mass of citric acid, $C(OH)(COOH)(CH_2COOH)_2$, (which contains three acidic protons) is required to neutralize the spill? 1 gallon = 3.785 L.
- **4.109** A sample of 7.75 g of Mg(OH)₂ is added to 25.0 mL of 0.200 *M* HNO₃. (a) Write the chemical equation for the reaction that occurs. (b) Which is the limiting reactant in the reaction? (c) How many moles of Mg(OH)₂, HNO₃, and Mg(NO₃)₂ are present after the reaction is complete?
- 4.110 Lead glass contains 18–40% by mass of PbO (instead of CaO in regular glass). Lead glass is still used industrially, but "lead crystal" drinking goblets are no longer considered safe, as the lead may leach out and cause toxic responses in humans. A particular 286-g lead crystal goblet that holds 450 mL of liquid is 27% PbO by mass, and it leaches 3.4 micrograms of lead every time it is filled. How many grams of sodium sulfide would be required to decontaminate all the lead in the entire goblet?
- **4.111** The average concentration of gold in seawater is $100 \, fM$ (femtomolar). Given that the price of gold is \$1764.20 per troy ounce (1 troy ounce = $31.103 \, g$), how many liters of seawater would you need to process to collect \$5000 worth of gold,

- assuming your processing technique captures only 50% of the gold present in the samples?
- **4.112** The mass percentage of chloride ion in a 25.00-mL sample of seawater was determined by titrating the sample with silver nitrate, precipitating silver chloride. It took 42.58 mL of 0.2997 *M* silver nitrate solution to reach the equivalence point in the titration. What is the mass percentage of chloride ion in seawater if its density is 1.025 g/mL?
- **4.113** The arsenic in a 1.22-g sample of a pesticide was converted to AsO₄³⁻ by suitable chemical treatment. It was then titrated using Ag⁺ to form Ag₃AsO₄ as a precipitate. (a) What is the oxidation state of As in AsO₄³⁻? (b) Name Ag₃AsO₄ by analogy to the corresponding compound containing phosphorus in place of arsenic. (c) If it took 25.0 mL of 0.102 *M* Ag⁺ to reach the equivalence point in this titration, what is the mass percentage of arsenic in the pesticide?
- 4.114 The U.S. standard for arsenate in drinking water requires that public water supplies must contain no greater than 10 parts per billion (ppb) arsenic. If this arsenic is present as arsenate, AsO₄³⁻, what mass of sodium arsenate would be present in a 1.00-L sample of drinking water that just meets the standard? Parts per billion is defined on a mass basis as

$$ppb = \frac{g \, solute}{g \, solution} \times 10^9$$

4.115 Federal regulations set an upper limit of 50 parts per million (ppm) of NH₃ in the air in a work environment [that is, 50 molecules of NH₃(g) for every million molecules in the air]. Air from a manufacturing operation was drawn through a solution containing 1.00×10^2 mL of 0.0105 M HCl. The NH₃ reacts with HCl according to:

$$NH_3(aq) + HCl(aq) \longrightarrow NH_4Cl(aq)$$

After drawing air through the acid solution for 10.0 min at a rate of $10.0 \, \text{L/min}$, the acid was titrated. The remaining acid needed 13.1 mL of $0.0588 \, M$ NaOH to reach the equivalence point. (a) How many grams of NH₃ were drawn into the acid solution? (b) How many ppm of NH₃ were in the air? (Air has a density of $1.20 \, \text{g/L}$ and an average molar mass of $29.0 \, \text{g/mol}$ under the conditions of the experiment.) (c) Is this manufacturer in compliance with regulations?

Design an Experiment

You are cleaning out a chemistry lab and find three unlabeled bottles, each containing white powder. Nearby these bottles are three loose labels: "Sodium sulfide," "Sodium bicarbonate" and "Sodium chloride." Let's design an experiment to figure out which label goes with which bottle.

(a) You could try to use the physical properties of the three solids to distinguish among them. Using an internet resource or the *CRC Handbook of Chemistry and Physics*, look up the melting points, aqueous solubilities, or other properties of these salts. Are the differences among these properties for each salt large enough to distinguish among them? If so, design a set of experiments to

distinguish each salt and therefore figure out which label goes on which bottle.

(b) You could use the chemical reactivity of each salt to distinguish it from the others. Which of these salts, if any, will act as an acid? A base? A strong electrolyte? Can any of these salts be easily oxidized or reduced? Can any of these salts react to produce a gas? Based on your answers to these questions, design a set of experiments to distinguish each salt and thus determine which label goes on which bottle.

Thermochemistry

Everything we do is connected in one way or another with energy. Not only our modern society but life itself depends on energy for its existence. The issues surrounding energy—its sources, production, distribution, and consumption—pervade conversations in science, politics, and economics, and relate to environmental concerns and public policy.

With the exception of the energy from the Sun, most of the energy used in our daily lives comes from chemical reactions. The combustion of gasoline, the production of electricity from coal, the heating of homes by natural gas, and the use of batteries to power electronic devices are all examples of how chemistry is used to produce energy. Even solar cells, such as those shown in the chapter-opening photo, rely on chemistry to produce the silicon and other materials that convert solar energy directly to electricity. In addition, chemical reactions provide the energy that sustains living systems. Plants use solar energy to carry out photosynthesis, allowing them to grow. The plants in turn provide food from which we humans derive the energy needed to move, maintain body temperature, and carry out all other bodily functions.

It is evident that the topic of energy is intimately related to chemistry. What exactly is energy, though, and what principles are involved in its production, consumption, and transformation from one form to another?

In this chapter we begin to explore energy and its changes. We are motivated not only by the impact of energy on so many aspects of our daily lives but also because if

➤ SOLAR PANELS. Each panel consists of an assembly of solar cells, also known as photovoltaic cells. Various materials have been used in solar cells, but crystalline silicon is most common.

5.1 THE NATURE OF ENERGY We begin by considering the nature of *energy* and the forms it takes, notably *kinetic energy* and *potential energy*. We discuss the units used in measuring energy and the fact that energy can be used to do *work* or to transfer *heat*. To study energy changes, we focus on a particular part of the universe, which we call the *system*. Everything else is called the *surroundings*.

5.2 THE FIRST LAW OF THERMODYNAMICS We then explore the *first law of thermodynamics*: Energy cannot be created or destroyed but can be transformed from one form to another or transferred between systems and surroundings. The energy possessed by a system is called its *internal energy*. Internal energy is a *state function*, a quantity whose value depends only on the current state of a system, not on how the system came to be in that state.

5.3 ENTHALPY Next, we encounter a state function called *enthalpy* that is useful because the change in enthalpy measures the quantity of heat energy gained or lost by a system in a process occurring under constant pressure.

5.4 ENTHALPIES OF REACTION We see that the enthalpy change associated with a chemical reaction is the enthalpies of the products minus the enthalpies of the reactants. This quantity is directly proportional to the amount of reactant consumed in the reaction

5.5 CALORIMETRY We next examine *calorimetry*, an experimental technique used to measure heat changes in chemical processes.

5.6 HESS'S LAW We observe that the enthalpy change for a given reaction can be calculated using appropriate enthalpy changes for related reactions. To do so, we apply *Hess's law*.

5.7 ENTHALPIES OF FORMATION We discuss how to establish standard values for enthalpy changes in chemical reactions and how to use them to calculate enthalpy changes for reactions.

5.8 FOODS AND FUELS Finally, we examine foods and fuels as sources of energy and discuss some related health and social issues.

we are to properly understand chemistry, we must understand the energy changes that accompany chemical reactions.

The study of energy and its transformations is known as **thermodynamics** (Greek: *thérme*-, "heat"; *dy'namis*, "power"). This area of study began during the Industrial Revolution in order to develop the relationships among heat, work, and fuels in steam engines. In this chapter we will examine the relationships between chemical reactions and energy changes that involve heat. This portion of thermodynamics is called **thermochemistry**. We will discuss additional aspects of thermodynamics in Chapter 19.

GO FIGURE

Why is a pitcher able to throw a baseball faster than he could throw a bowling ball?

(a)

(h)

▲ Figure 5.1 Work and heat, two forms of energy. (a) Work is energy used to cause an object to move. (b) Heat is energy used to cause the temperature of an object to increase.

5.1 | **Energy**

Unlike matter, energy does not have mass and cannot be held in our hands, but its effects can be observed and measured. **Energy** is the capacity to do work or transfer heat. Before we can make any use of this definition we must understand the concepts of work and heat. **Work** is the energy used to cause an object to move against a force, and **heat** is the energy used to cause the temperature of an object to increase (**Figure 5.1**). Before we examine these definitions more closely, let's first consider the ways in which matter can possess energy and how that energy can be transferred from one piece of matter to another.

Kinetic Energy and Potential Energy

Objects, whether they are baseballs or molecules, can possess **kinetic energy**, the energy of *motion*. The magnitude of the kinetic energy, E_k , of an object depends on its mass, m, and speed, v:

$$E_k = \frac{1}{2} m v^2 \tag{5.1}$$

Thus, the kinetic energy of an object increases as its speed increases. For example, a car moving at 55 miles per hour (mi/h) has greater kinetic energy than it does at 25 mi/h. For a given speed the kinetic energy increases with increasing mass. Thus, a large truck traveling at 55 mi/h has greater kinetic energy than a small sedan traveling at the same speed because the truck has the greater mass.

In chemistry, we are interested in the kinetic energy of atoms and molecules. Although too small to be seen, these particles have mass and are in motion and, therefore, possess kinetic energy.

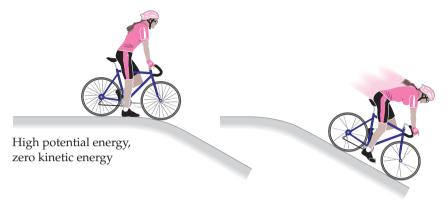

All other kinds of energy—the energy stored in a stretched spring, in a weight held above your head, or in a chemical bond, for example—are potential energy. An object has **potential energy** by virtue of its position relative to other objects. Potential energy is, in essence, the "stored" energy that arises from the attractions and repulsions an object experiences in relation to other objects.

We are familiar with many instances in which potential energy is converted into kinetic energy. For example, think of a cyclist poised at the top of a hill (**Figure 5.2**). Because of the attractive force of gravity, the potential energy of the cyclist and her bicycle is greater at the top of the hill than at the bottom. As a result, the bicycle easily moves down the hill with increasing speed. As it does so, potential energy is converted into kinetic energy. The potential energy decreases as the bicycle rolls down the hill, but its kinetic energy increases as the speed increases (Equation 5.1). This example illustrates that forms of energy are interconvertible.

Gravitational forces play a negligible role in the ways that atoms and molecules interact with one another. Forces that arise from electrical charges are more important when dealing with atoms and molecules. One of the most important forms of potential energy in chemistry is *electrostatic potential energy*, $E_{\rm el}$, which arises from

GO FIGURE

Suppose the bicyclist is coasting (not pedaling) at constant speed on a flat road and begins to go up a hill. If she does not start pedaling, what happens to her speed? Why?

Decreasing potential energy, increasing kinetic energy

▲ Figure 5.2 Potential energy and kinetic energy. The potential energy initially stored in the motionless bicycle and rider at the top of the hill is converted to kinetic energy as the bicycle moves down the hill and loses potential energy.

the interactions between charged particles. This energy is proportional to the electrical charges on the two interacting objects, Q_1 and Q_2 , and inversely proportional to the distance, d, separating them:

$$E_{\rm el} = \frac{\kappa Q_1 \, Q_2}{d} \tag{5.2}$$

In this equation κ is the proportionality constant, 8.99×10^9 J-m/C², that relates the units for energy to the units for the charges and their distance of separation. C is the coulomb, a unit of electrical charge ∞ (Section 2.2), and J is the joule, a unit of energy we will discuss soon.* At the molecular level, the electrical charges Q_1 and Q_2 are typically on the order of magnitude of the charge of the electron (1.60 \times 10⁻¹⁹ C).

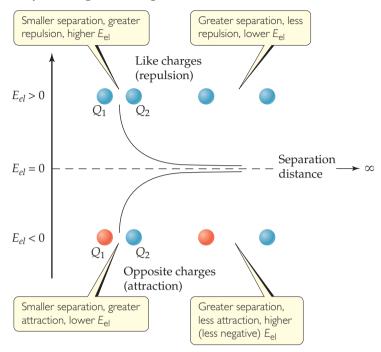

Equation 5.2 shows that the electrostatic potential energy goes to zero as d becomes infinite. Thus, the zero of electrostatic potential energy is defined as infinite separation of the charged particles. Figure 5.3 illustrates how $E_{\rm el}$ behaves as the distance between two charges changes. When Q_1 and Q_2 have the same sign (for example, both positive), the two charged particles repel each other, and a repulsive force pushes them apart. In this case, $E_{\rm el}$ is positive, and the potential energy decreases as the particles move farther apart. When Q_1 and Q_2 have opposite signs, the particles attract each other, and an attractive force pulls them toward each other. In this case, $E_{\rm el}$ is negative, and the potential energy increases (becomes less negative) as the particles move apart.

One of our goals in chemistry is to relate the energy changes seen in the macroscopic world to the kinetic or potential energy of substances at the molecular level. Many substances—fuels, for example—release energy when they react. The *chemical energy* of a fuel is due to the potential energy stored in the arrangements of its atoms.

^{*}We read the combined units J-m/C² as joule-meters per coulomb squared. You may see combinations of units such as J-m/C² expressed with dots separating units instead of short dashes ($J \cdot m/C^2$) or with dashes or dots totally absent ($J \cdot m/C^2$).

GO FIGURE

A positively charged particle and a negatively charged particle are initially far apart. What happens to their electrostatic potential energy as they are brought closer together?

▲ Figure 5.3 Electrostatic potential energy. At finite separation distances for two charged particles, *E*_{el} is positive for like charges and negative for opposite charges. As the particles move farther apart, their electrostatic potential energy approaches zero.

When a fuel burns, this chemical energy is converted to *thermal energy*, energy associated with temperature. The increase in thermal energy arises from the increased molecular motion and hence increased kinetic energy at the molecular level.

Give It Some Thought

The cyclist and bicycle illustrated in Figure 5.2 come to a stop at the bottom of the hill.

- (a) Is the potential energy the same as it was at the top of the hill?
- (b) Is the kinetic energy the same as it was at the top of the hill?

Units of Energy

The SI unit for energy is the **joule** (pronounced "jool"), J, in honor of James Joule (1818–1889), a British scientist who investigated work and heat: $1 \text{ J} = 1 \text{ kg-m}^2/\text{s}^2$. Equation 5.1 shows that a mass of 2 kg moving at a speed of 1 m/s possesses a kinetic energy of 1 J:

$$E_k = \frac{1}{2} m v^2 = \frac{1}{2} (2 \text{ kg}) (1 \text{ m/s})^2 = 1 \text{ kg-m}^2/\text{s}^2 = 1 \text{ J}$$

Because a joule is not a large amount of energy, we often use *kilojoules* (kJ) in discussing the energies associated with chemical reactions.

Traditionally, energy changes accompanying chemical reactions have been expressed in calories, a non–SI unit still widely used in chemistry, biology, and biochemistry. A **calorie** (cal) was originally defined as the amount of energy required to raise the temperature of 1 g of water from 14.5 to 15.5 °C. A calorie is now defined in terms of the joule:

$$1 \text{ cal} = 4.184 \text{ J (exactly)}$$

A related energy unit used in nutrition is the nutritional *Calorie* (note the capital C): 1 Cal = 1000 cal = 1 kcal.

System and Surroundings

When analyzing energy changes, we need to focus on a limited and well-defined part of the universe to keep track of the energy changes that occur. The portion we single out for study is called the **system**; everything else is called the **surroundings**. When we study the energy change that accompanies a chemical reaction in a laboratory, the reactants and products constitute the system. The container and everything beyond it are considered the surroundings.

Systems may be open, closed, or isolated. An *open* system is one in which matter and energy can be exchanged with the surroundings. An uncovered pot of boiling water on a stove, such as that in Figure 5.1(b), is an open system: Heat comes into the system from the stove, and water is released to the surroundings as steam.

The systems we can most readily study in thermochemistry are called *closed systems*—systems that can exchange energy but not matter with their surroundings. For example, consider a mixture of hydrogen gas, H_2 , and oxygen gas, O_2 , in a cylinder fitted with a piston (\triangleright Figure 5.4). The system is just the hydrogen and oxygen; the cylinder, piston, and everything beyond them (including us) are the surroundings. If the gases react to form water, energy is liberated:

$$2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(g) + energy$$

Although the chemical form of the hydrogen and oxygen atoms in the system is changed by this reaction, the system has not lost or gained mass, which means it has not exchanged any matter with its surroundings. However, it can exchange energy with its surroundings in the form of *work* and *heat*.

An *isolated* system is one in which neither energy nor matter can be exchanged with the surroundings. An insulated thermos containing hot coffee approximates an isolated system. We know, however, that the coffee eventually cools, so it is not perfectly isolated.

Give It Some Thought

Is a human being an isolated, closed, or open system?

Transferring Energy: Work and Heat

Figure 5.1 illustrates the two ways we experience energy changes in our everyday lives—in the form of work and in the form of heat. In Figure 5.1(a) work is done as energy is transferred from the pitcher's arm to the ball, directing it toward the plate at high speed. In Figure 5.1(b) energy is transferred in the form of heat. Causing the motion of an object against a force and causing a temperature change are the two general ways that energy can be transferred into or out of a system.

We define *work*, *w*, as the energy transferred when a *force* moves an object. A **force** is any push or pull exerted on an object. The magnitude of the work equals the product of the force, *F*, and the distance, *d*, the object moves:

$$w = F \times d \tag{5.3}$$

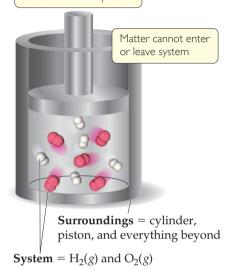

We perform work, for example, when we lift an object against the force of gravity. If we define the object as the system, then we—as part of the surroundings—are performing work on that system, transferring energy to it.

The other way in which energy is transferred is as heat. *Heat* is the energy transferred from a hotter object to a colder one. A combustion reaction, such as the burning of natural gas illustrated in Figure 5.1(b), releases the chemical energy stored in the molecules of the fuel. (Section 3.2) If we define the substances involved in the reaction as the system and everything else as the surroundings, we find that the released energy causes the temperature of the system to increase. Energy in the form of heat is then transferred from the hotter system to the cooler surroundings.

If the piston is pulled upward so that it sits halfway between the position shown and the top of the cylinder, is the system still closed?

Energy can enter or leave system as heat or as work done on piston

▲ Figure 5.4 A closed system.

SAMPLE EXERCISE 5.1 Describing and Calculating Energy Changes

A bowler lifts a 5.4-kg (12-lb) bowling ball from ground level to a height of 1.6 m (5.2 ft) and then drops it. (a) What happens to the potential energy of the ball as it is raised? (b) What quantity of work, in J, is used to raise the ball? (c) After the ball is dropped, it gains kinetic energy. If all the work done in part (b) has been converted to kinetic energy by the time the ball strikes the ground, what is the ball's speed just before it hits the ground? (*Note*: The force due to gravity is $F = m \times g$, where m is the mass of the object and g is the gravitational constant; $g = 9.8 \text{ m/s}^2$.)

SOLUTION

Analyze We need to relate the potential energy of the bowling ball to its position relative to the ground. We then need to establish the relationship between work and the change in the ball's potential energy. Finally, we need to connect the change in potential energy when the ball is dropped with the kinetic energy attained by the ball.

Plan We can calculate the work done in lifting the ball by using Equation 5.3: $w = F \times d$. The kinetic energy of the ball just before it hits the ground equals its initial potential energy. We can use the kinetic energy and Equation 5.1 to calculate the speed, v, just before impact.

Solve

- (a) Because the ball is raised above the ground, its potential energy relative to the ground increases
- (b) The ball has a mass of 5.4 kg and is lifted 1.6 m. To calculate the work performed to raise the ball, we use Equation 5.3 and $F = m \times g$ for the force that is due to gravity:

$$w = F \times d = m \times g \times d = (5.4 \text{ kg})(9.8 \text{ m/s}^2)(1.6 \text{ m}) = 85 \text{ kg-m}^2/\text{s}^2 = 85 \text{ J}$$

Thus, the bowler has done 85 J of work to lift the ball to a height of 1.6 m.

(c) When the ball is dropped, its potential energy is converted to kinetic energy. We assume that the kinetic energy just before the ball hits the ground is equal to the work done in part (b), 85 J:

$$E_k = \frac{1}{2} m v^2 = 85 \text{ J} = 85 \text{ kg-m}^2/\text{s}^2$$

We can now solve this equation for v:

$$v^{2} = \left(\frac{2E_{k}}{m}\right) = \left(\frac{2(85 \text{ kg} \cdot \text{m}^{2}/\text{s}^{2})}{5.4 \text{ kg}}\right) = 31.5 \text{ m}^{2}/\text{s}^{2}$$
$$v = \sqrt{31.5 \text{ m}^{2}/\text{s}^{2}} = 5.6 \text{ m/s}$$

Check Work must be done in (b) to increase the potential energy of the ball, which is in accord with our experience. The units are appropriate in (b) and (c). The work is in units of J and the speed in units of m/s. In (c) we carry an additional digit in the intermediate calculation involving the square root, but we report the final value to only two significant figures, as appropriate.

Comment A speed of 1 m/s is roughly 2 mph, so the bowling ball has a speed greater than 10 mph just before impact.

Practice Exercise 1

Which of the following objects has the greatest kinetic energy? (a) a 500-kg motorcycle moving at 100 km/h, (b) a 1,000-kg car moving at 50 km/h, (c) a 1,500-kg car moving at 30 km/h, (d) a 5,000-kg truck moving at 10 km/h, (e) a 10,000-kg truck moving at 5 km/h.

Practice Exercise 2

What is the kinetic energy, in J, of (a) an Ar atom moving at a speed of 650 m/s, (b) a mole of Ar atoms moving at 650 m/s? (*Hint*: 1 amu = 1.66×10^{-27} kg.)

5.2 | The First Law of Thermodynamics

We have seen that the potential energy of a system can be converted into kinetic energy, and vice versa. We have also seen that energy can be transferred back and forth between a system and its surroundings in the forms of work and heat. All of these conversions and transfers proceed in accord with one of the most important observations in science: *Energy can be neither created nor destroyed*. Any energy that is lost by a system must be gained by the surroundings, and vice versa. This important observation—that *energy is conserved*—is known as the **first law of thermodynamics**. To apply this law quantitatively, let's first define the energy of a system more precisely.

Internal Energy

The **internal energy**, E, of a system is the sum of *all* the kinetic and potential energies of the components of the system. For the system in Figure 5.4, for example, the internal energy includes not only the motions and interactions of the H_2 and O_2 molecules but also the motions and interactions of their component nuclei and electrons. We generally do not know the numerical value of a system's internal energy. In thermodynamics, we are mainly concerned with the *change* in E (and, as we shall see, changes in other quantities as well) that accompanies a change in the system.

Imagine that we start with a system with an initial internal energy E_{initial} . The system then undergoes a change, which might involve work being done or heat being transferred. After the change, the final internal energy of the system is E_{final} . We define the *change* in internal energy, denoted ΔE (read "delta E"),* as the difference between E_{final} and E_{initial} :

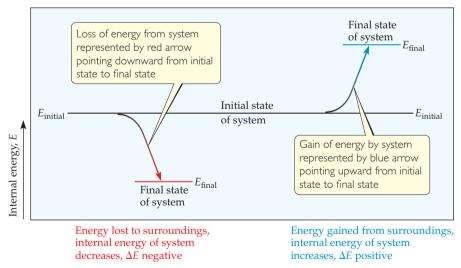

$$\Delta E = E_{\text{final}} - E_{\text{initial}}$$
 [5.4]

We generally cannot determine the actual values of E_{final} and E_{initial} for any system of practical interest. Nevertheless, we can determine the value of ΔE experimentally by applying the first law of thermodynamics.

Thermodynamic quantities such as ΔE have three parts: (1) a number and (2) a unit, which together give the magnitude of the change, and (3) a sign that gives the direction. A *positive* value of ΔE results when $E_{\text{final}} > E_{\text{initial}}$, indicating that the system has gained energy from its surroundings. A *negative* value of ΔE results when $E_{\text{final}} < E_{\text{initial}}$, indicating that the system has lost energy to its surroundings. Notice that we are taking the point of view of the system rather than that of the surroundings in discussing the energy changes. We need to remember, however, that any increase in the energy of the system is accompanied by a decrease in the energy of the surroundings, and vice versa. These features of energy changes are summarized in ∇ Figure 5.5.

What is the value of ΔE if E_{final} equals E_{initial} ?

▲ Figure 5.5 Changes in internal energy.

In a chemical reaction, the initial state of the system refers to the reactants and the final state refers to the products. In the reaction

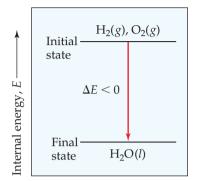

$$2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(l)$$

for instance, the initial state is the $2 H_2(g) + O_2(g)$ and the final state is the $2 H_2O(l)$. When hydrogen and oxygen form water at a given temperature, the system loses energy to the surroundings. Because energy is lost from the system, the internal energy of the products (final state) is less than that of the reactants (initial state), and ΔE for the process is

^{*}The symbol Δ is commonly used to denote *change*. For example, a change in height, h, can be represented by Δh .

GO FIGURE

The internal energy for a mixture of Mg(s) and $Cl_2(g)$ is greater than that of $MgCl_2(s)$. Sketch an energy diagram that represents the reaction $MgCl_2(s) \longrightarrow Mg(s) + Cl_2(g)$.

 $E_{\rm initial}$ greater than $E_{\rm final}$; therefore, energy is released from system to surroundings during reaction and $\Delta E < 0$

▲ Figure 5.6 Energy diagram for the reaction $2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(I)$.

negative. Thus, the *energy diagram* in \triangleleft **Figure 5.6** shows that the internal energy of the mixture of H₂ and O₂ is greater than that of the H₂O produced in the reaction.

Relating ΔE to Heat and Work

As we noted in Section 5.1, a system may exchange energy with its surroundings in two general ways: as heat or as work. The internal energy of a system changes in magnitude as heat is added to or removed from the system or as work is done on or by the system. If we think of internal energy as the system's bank account of energy, we see that deposits or withdrawals can be made either in the form of heat or in the form of work. Deposits increase the energy of the system (positive ΔE), whereas withdrawals decrease the energy of the system (negative ΔE).

We can use these ideas to write a useful algebraic expression of the first law of thermodynamics. When a system undergoes any chemical or physical change, the accompanying change in internal energy, ΔE , is the sum of the heat added to or liberated from the system, q, and the work done on or by the system, w:

$$\Delta E = q + w \tag{5.5}$$

When heat is added to a system or work is done on a system, its internal energy increases. Therefore, when heat is transferred to the system from the surroundings, q has a positive value. Adding heat to the system is like making a deposit to the energy account—the energy of the system increases (\blacktriangledown Figure 5.7). Likewise, when work is done on the

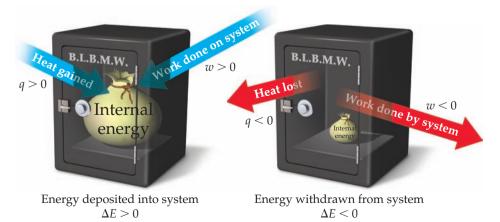

GO FIGURE

Suppose a system receives a "deposit" of 50 J of work from the surroundings and loses a "withdrawal" of 85 J of heat to the surroundings. What is the magnitude and the sign of ΔE for this process?

System is interior of vault

▲ Figure 5.7 Sign conventions for heat and work. Heat, *q*, gained by a system and work, *w*, done on a system are both positive quantities, corresponding to "deposits" of internal energy into the system. Conversely, heat transferred from the system to the surroundings and work done by the system on the surroundings are both "withdrawals" of internal energy from the system.

Table 5.1 Sign Conventions for q, w, and ΔE

For q	+ means system <i>gains</i> heat	— means system <i>loses</i> heat
For w	+ means work done <i>on</i> system	— means work done <i>by</i> system
For ΔE	+ means <i>net gain</i> of energy by system	— means <i>net loss</i> of energy by system

system by the surroundings, *w* has a positive value. Conversely, both the heat lost by the system to the surroundings and the work done by the system on the surroundings have negative values; that is, they lower the internal energy of the system. They are energy withdrawals and lower the amount of energy in the system's account.

The sign conventions for q, w, and ΔE are summarized in \triangle **Table 5.1**. Notice that any energy entering the system as either heat or work carries a positive sign.

SAMPLE EXERCISE 5.2 Relating Heat and Work to Changes of Internal Energy

Gases A(g) and B(g) are confined in a cylinder-and-piston arrangement like that in Figure 5.4 and react to form a solid product C(s): $A(g) + B(g) \longrightarrow C(s)$. As the reaction occurs, the system loses 1150 J of heat to the surroundings. The piston moves downward as the gases react to form a solid. As the volume of the gas decreases under the constant pressure of the atmosphere, the surroundings do 480 J of work on the system. What is the change in the internal energy of the system?

SOLUTION

Analyze The question asks us to determine ΔE , given information about q and w.

Plan We first determine the signs of q and w (Table 5.1) and then use Equation 5.5, $\Delta E = q + w$, to calculate ΔE .

Solve Heat is transferred from the system to the surroundings, and work is done on the system by the surroundings, so q is negative and w is positive: q = -1150 J and w = 480 kJ. Thus,

$$\Delta E = q + w = (-1150 \,\text{J}) + (480 \,\text{J}) = -670 \,\text{J}$$

The negative value of ΔE tells us that a net quantity of 670 J of energy has been transferred from the system to the surroundings.

Comment You can think of this change as a decrease of 670 J in the net value of the system's energy bank account (hence, the negative sign); 1150 J is withdrawn in the form of heat while 480 J is deposited in the form of work. Notice that as the volume of the gases decreases, work is being done *on* the system *by* the surroundings, resulting in a deposit of energy.

Practice Exercise 1

Consider the following four cases: (i) A chemical process in which heat is absorbed, (ii) A change in which $q=30\,\mathrm{J}$, $w=44\,\mathrm{J}$, (iii) A process in which a system does work on its surroundings with no change in q, (iv) A process in which work is done on a system and an equal amount of heat is withdrawn.

In how many of these cases does the internal energy of the system decrease? (a) 0, (b) 1, (c) 2, (d) 3, (e) 4.

Practice Exercise 2

Calculate the change in the internal energy for a process in which a system absorbs 140 J of heat from the surroundings and does 85 J of work on the surroundings.

Endothermic and Exothermic Processes

Because transfer of heat to and from the system is central to our discussion in this chapter, we have some special terminology to indicate the direction of transfer. When a process occurs in which the system absorbs heat, the process is called **endothermic** (*endo-* means "into"). During an endothermic process, such as the melting of ice, heat flows *into* the system from its surroundings [Figure 5.8(a)]. If we, as part of the surroundings, touch a container in which ice is melting, the container feels cold to us because heat has passed from our hand to the container.

A process in which the system loses heat is called **exothermic** (*exo*- means "out of"). During an exothermic process, such as the combustion of gasoline, heat *exits* or flows *out* of the system into the surroundings [Figure 5.8(b)].

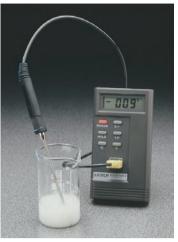

Give It Some Thought

When $H_2(g)$ and $O_2(g)$ react to form $H_2O(I)$, heat is released to the surroundings. Consider the reverse reaction, namely, the formation of $H_2(g)$ and $O_2(g)$ from $H_2O(I)$: 2 $H_2O(I) \rightarrow$ 2 $H_2(g) + O_2(g)$. Is this reaction exothermic or endothermic? (*Hint:* Refer to Figure 5.6.)

System: reactants + products

Surroundings: solvent, initially at room temperature

(a) An endothermic reaction

Heat flows from surroundings into system, temperature of surroundings drops, thermometer reads temperature well below room temperature **System:** reactants + products

Surroundings: air around reactants

(b) An exothermic reaction

Heat flows (violently) from system into surroundings, temperature of surroundings increases

▲ Figure 5.8 Endothermic and exothermic reactions. (a) When ammonium thiocyanate and barium hydroxide octahydrate are mixed at room temperature, the temperature drops. (b) The reaction of powdered aluminum with Fe_2O_3 (the thermite reaction) proceeds vigorously, releasing heat and forming Al_2O_3 and molten iron.

State Functions

Although we usually have no way of knowing the precise value of the internal energy of a system, E, it does have a fixed value for a given set of conditions. The conditions that influence internal energy include the temperature and pressure. Furthermore, the internal energy of a system is proportional to the total quantity of matter in the system because energy is an extensive property. ∞ (Section 1.3)

Suppose we define our system as 50 g of water at 25 °C (∇ Figure 5.9). The system could have reached this state by cooling 50 g of water from 100 to 25 °C or by melting 50 g of ice and subsequently warming the water to 25 °C. The internal energy of the water at 25 °C is the same in either case. Internal energy is an example of a **state function**, a property of a system that is determined by specifying the system's condition, or state (in terms of temperature, pressure, and so forth). The value of a state function depends only on the present state of the system, not on the path the system took to reach that state. Because E is a state function, ΔE depends only on the initial and final states of the system, not on how the change occurs.

Initially hot water cools to water at 25 °C; once this temperature is reached, system has internal energy *E*

Ice warms up to water at 25 °C; once this temperature is reached, system has internal energy *E*

▲ Figure 5.9 Internal energy, *E*, a state function. Any state function depends only on the present state of the system and not on the path by which the system arrived at that state.

An analogy may help you understand the difference between quantities that are state functions and those that are not. Suppose you drive from Chicago, which is 596 ft above sea level, to Denver, which is 5280 ft above sea level. No matter which route you take, the altitude change is 4684 ft. The distance you travel, however, depends on your route. Altitude is analogous to a state function because the change in altitude

is independent of the path taken. Distance traveled is not a state function.

Some thermodynamic quantities, such as E, are state functions. Other quantities, such as Q and W, are not. This means that, although $\Delta E = Q + W$ does not depend on how the change occurs, the specific amounts of heat and work depend on the way in which the change occurs. Thus, if changing the path by which a system goes from an initial state to a final state increases the value of Q, that path change will also decrease the value of W by exactly the same amount. The result is that W is the same for the two paths.

We can illustrate this principle using a flashlight battery as our system. As the battery is discharged, its internal energy decreases as the energy stored in the battery is released to the surroundings. In \triangleright Figure 5.10, we consider two possible ways of discharging the battery at constant temperature. If a wire shorts out the battery, no work is accomplished because nothing is moved against a force. All the energy lost from the battery is in the form of heat. (The wire gets warmer and releases heat to the surroundings.) If the battery is used to make a motor turn, the discharge produces work. Some heat is released, but not as much as when the battery is shorted out. We see that the magnitudes of q and w must be different for these two cases. If the initial and final states of the battery are identical in the two cases, however, then $\Delta E = q + w$ must be the same in both cases because E is a state function. Remember: ΔE depends only on the initial and final states of the system, not on the specific path taken from the initial to the final state.

Give It Some Thought

In what ways is the balance in your checkbook a state function?

5.3 | Enthalpy

The chemical and physical changes that occur around us, such as photosynthesis in the leaves of a plant, evaporation of water from a lake, or a reaction in an open beaker in a laboratory, occur under the essentially constant pressure of Earth's atmosphere.* These changes can result in the release or absorption of heat and can be accompanied by work done by or on the system. In exploring these changes, it is useful to have a thermodynamic function that is a state function and relates mainly to heat flow. Under conditions of constant pressure, a thermodynamic quantity called *enthalpy* (from the Greek *enthalpein*, "to warm") provides such a function.

Enthalpy, which we denote by the symbol *H*, is defined as the internal energy plus the product of the *pressure*, *P*, and *volume*, *V*, of the system:

$$H = E + PV ag{5.6}$$

Like internal energy *E*, both *P* and *V* are state functions—they depend only on the current state of the system and not on the path taken to that state. Because energy, pressure, and volume are all state functions, enthalpy is also a state function.

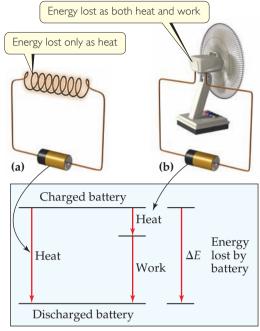

Pressure-Volume Work

To better understand the significance of enthalpy, recall from Equation 5.5 that ΔE involves not only the heat q added to or removed from the system but also the work w done by or on the system. Most commonly, the only kind of work produced by chemical or physical changes open to the atmosphere is the mechanical work associated with a change in volume. For example, when the reaction of zinc metal with hydrochloric acid solution

$$Zn(s) + 2 H^{+}(aq) \rightarrow Zn^{2+}(aq) + H_{2}(g)$$
 [5.7]

▲ GO FIGURE

If the battery is defined as the system, what is the sign on *w* in part (b)?

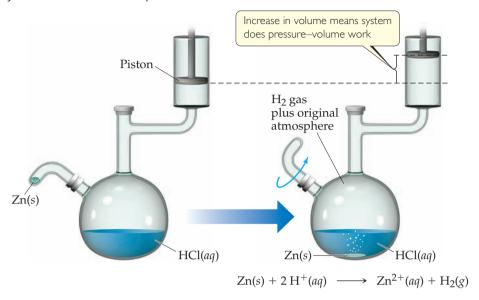

▲ Figure 5.10 Internal energy is a state function, but heat and work are not. (a) A battery shorted out by a wire loses energy to the surroundings only as heat; no work is performed. (b) A battery discharged through a motor loses energy as work (to make the fan turn) and also loses some energy as heat. The value of ΔE is the same for both processes even though the values of q and w in (a) are different from those in (b).

^{*}You are probably familiar with the notion of atmospheric pressure from a previous course in chemistry. We will discuss it in detail in Chapter 10. Here we need realize only that the atmosphere exerts a pressure on the surface of Earth that is nearly constant.

GO FIGURE

If the amount of zinc used in the reaction is increased, will more work be done by the system? Is there additional information you need to answer this question?

▲ Figure 5.11 A system that does work on its surroundings.

is run at constant pressure in the apparatus illustrated in \triangle Figure 5.11, the piston moves up or down to maintain a constant pressure in the vessel. If we assume for simplicity that the piston has no mass, the pressure in the apparatus is the same as atmospheric pressure. As the reaction proceeds, H_2 gas forms, and the piston rises. The gas within the flask is thus doing work on the surroundings by lifting the piston against the force of atmospheric pressure.

The work involved in the expansion or compression of gases is called **pressure-volume work** (P–V work). When pressure is constant in a process, as in our preceding example, the sign and magnitude of the pressure–volume work are given by

$$w = -P \Delta V \tag{5.8}$$

where P is pressure and $\Delta V = V_{\rm final} - V_{\rm initial}$ is the change in volume of the system. The pressure P is always either a positive number or zero. If the volume of the system expands, then ΔV is positive as well. The negative sign in Equation 5.8 is necessary to conform to the sign convention for w (Table 5.1). When a gas expands, the system does work on the surroundings, as indicated by a negative value of w. (The negative sign \times positive $P \times$ positive ΔV results in a negative number for w.) On the other hand, if the gas is compressed, ΔV is negative (the volume decreases), and Equation 5.8 indicates that w is therefore positive, meaning work is done on the system by the surroundings. "A Closer Look: Energy, Enthalpy, and P-V Work" box discusses pressure–volume work in detail, but all you need to keep in mind for now is Equation 5.8, which applies to processes occurring at constant pressure.

The units of work obtained by using Equation 5.8 will be those of pressure (usually atm) multiplied by those of volume (usually L). To express the work in the more familiar unit of joules, we use the conversion factor 1 L-atm = 101.3 J.

Give It Some Thought

If a system does not change its volume during the course of a process, does it do pressure–volume work?

SAMPLE EXERCISE 5.3

A fuel is burned in a cylinder equipped with a piston. The initial volume of the cylinder is 0.250 L, and the final volume is 0.980 L. If the piston expands against a constant pressure of 1.35 atm, how much work (in J) is done? (1 L-atm = 101.3 J)

SOLUTION

Analyze We are given an initial volume and a final volume from which we can calculate ΔV . We are also given the pressure, P. We are asked to calculate work, w.

Plan The equation $w = -P \Delta V$ allows us to calculate the work done by the system from the given information.

Solve The volume change is

$$\Delta V = V_{\text{final}} - V_{\text{initial}} = 0.980 \,L - 0.250 \,L = 0.730 \,L$$

Thus, the quantity of work is

$$w = -P\Delta V = -(1.35 \text{ atm})(0.730 \text{ L}) = -0.9855 \text{ L-atm}$$

Converting L-atm to J, we have

$$-(0.9855 \text{ L-atm}) \left(\frac{101.3 \text{ J}}{1 \text{ L-atm}} \right) = -99.8 \text{ J}$$

Check The significant figures are correct (3), and the units are the requested ones for energy (J). The negative sign is consistent with an expanding gas doing work on its surroundings.

Practice Exercise 1

If a balloon is expanded from 0.055 to 1.403 L against an external pressure of 1.02 atm, how many L-atm of work is done? (a) -0.056 L-atm, (b) -1.37 L-atm, (c) 1.43 L-atm, (d) 1.49 L-atm, (e) 139 L-atm.

Practice Exercise 2

Calculate the work, in J, if the volume of a system contracts from 1.55 to 0.85 L at a constant pressure of 0.985 atm.

Enthalpy Change

Let's now return to our discussion of enthalpy. When a change occurs at constant pressure, the change in enthalpy, ΔH , is given by the relationship

$$\Delta H = \Delta (E + PV)$$

$$= \Delta E + P\Delta V \quad \text{(constant pressure)}$$
 [5.9]

That is, the change in enthalpy equals the change in internal energy plus the product of the constant pressure and the change in volume.

Recall that $\Delta E = q + w$ (Equation 5.5) and that the work involved in the expansion or compression of a gas is $w = -P \Delta V$ (at constant pressure). Substituting -w for $P \Delta V$ and q + w for ΔE into Equation 5.9, we have

$$\Delta H = \Delta E + P \Delta V = (q_P + w) - w = q_P$$
 [5.10]

The subscript P on q indicates that the process occurs at constant pressure. Thus, the change in enthalpy equals the heat q_P gained or lost at constant pressure. Because q_P is something we can either measure or calculate and because so many physical and chemical changes of interest to us occur at constant pressure, enthalpy is a more useful function for most reactions than is internal energy. In addition, for most reactions the difference in ΔH and ΔE is small because P ΔV is small.

When ΔH is positive (that is, when q_P is positive), the system has gained heat from the surroundings (Table 5.1), which means the process is endothermic. When ΔH is negative, the system has released heat to the surroundings, which means the process is exothermic. To continue the bank analogy of Figure 5.7, under constant pressure, an endothermic process deposits energy in the system in the form of heat and an exothermic process withdraws energy in the form of heat (\triangleright Figure 5.12).

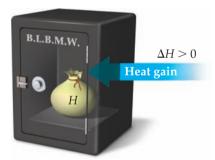

Give It Some Thought

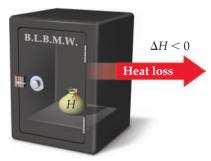

When a reaction occurs in a flask, you notice that the flask gets colder. What is the sign of ΔH ?

Because H is a state function, ΔH (which equals q_P) depends only on the initial and final states of the system, not on how the change occurs. At first glance this statement might seem to contradict our discussion in Section 5.2, in which we said that q is *not* a state function. There is no contradiction, however, because the relationship between ΔH and q_P has special limitations that only P-V work is involved and that the pressure is constant.

(a) An endothermic reaction

(b) An exothermic reaction

 ΔH is amount of heat that flows into or out of system under constant pressure

▲ Figure 5.12 Endothermic and exothermic processes. (a) An endothermic process $(\Delta H > 0)$ deposits heat into the system. (b) An exothermic process $(\Delta H < 0)$ withdraws heat from the system.

SAMPLE EXERCISE 5.4 Determining the Sign of ΔH

Indicate the sign of the enthalpy change, ΔH , in the following processes carried out under atmospheric pressure and indicate whether each process is endothermic or exothermic: (a) An ice cube melts; (b) 1 g of butane (C_4H_{10}) is combusted in sufficient oxygen to give complete combustion to CO_2 and H_2O .

SOLUTION

Analyze Our goal is to determine whether ΔH is positive or negative for each process. Because each process occurs at constant pressure, the enthalpy change equals the quantity of heat absorbed or released, $\Delta H = q_P$.

Plan We must predict whether heat is absorbed or released by the system in each process. Processes in which heat is absorbed are endothermic and have a positive sign for ΔH ; those in which heat is released are exothermic and have a negative sign for ΔH .

Solve In (a) the water that makes up the ice cube is the system. The ice cube absorbs heat from the surroundings as it melts, so ΔH is positive and the process is endothermic. In (b) the system is the 1 g of butane and the oxygen required to combust it. The combustion of butane in oxygen gives off heat, so ΔH is negative and the process is exothermic.

Practice Exercise 1

A chemical reaction that gives off heat to its surroundings is said $\underline{\hspace{0.5cm}}$ and has a $\underline{\hspace{0.5cm}}$ value of ΔH .

- (a) endothermic, positive (c) exothermic, positive
- (b) endothermic, negative (d) exothermic, negative

Practice Exercise 2

Molten gold poured into a mold solidifies at atmospheric pressure. With the gold defined as the system, is the solidification an exothermic or endothermic process?

in cylinder

A Closer Look

Energy, Enthalpy, and P-V Work

In chemistry we are interested mainly in two types of work: electrical work and mechanical work done by expanding gases. We focus here on the latter, called pressure-volume, or P-V, work. Expanding gases in the cylinder of an automobile engine do *P*–*V* work on the piston; this work eventually turns the wheels. Expanding gases from an open reaction vessel do *P*–*V* work on the atmosphere. This work accomplishes nothing in a practical sense, but we must keep track of all work, useful or not, when monitoring energy changes in a system.

Let's consider a gas confined to a cylinder with a movable piston of cross-sectional area A (∇ Figure 5.13). A downward force F acts on the piston. The *pressure*, P, on the gas is the force per area: P = F/A.

System does work $w = -P\Delta V$ on surroundings as gas expands, pushing piston up distance Δh P = F/AP = F/A Δh ΔV Volume change Gas enclosed

Final

state

▲ Figure 5.13 Pressure-volume work. The amount of work done by the system on the surroundings is $w = -P\Delta V$.

Cross-sectional

area = A

Initial

state

We assume that the piston is massless and that the only pressure acting on it is the atmospheric pressure that is due to Earth's atmosphere, which we assume to be constant.

Suppose the gas expands and the piston moves a distance Δh . From Equation 5.3, the magnitude of the work done by the system is

Magnitude of work = force
$$\times$$
 distance = $F \times \Delta h$ [5.11]

We can rearrange the definition of pressure, P = F/A, to $F = P \times A$. The volume change, ΔV , resulting from the movement of the piston is the product of the cross-sectional area of the piston and the distance it moves: $\Delta V = A \times \Delta h$. Substituting into Equation 5.11 gives

Magnitude of work =
$$F \times \Delta h = P \times A \times \Delta h$$

= $P \times \Delta V$

Because the system (the confined gas) does work on the surroundings, the work is a negative quantity:

$$w = -P \,\Delta V \tag{5.12}$$

Now, if P-V work is the only work that can be done, we can substitute Equation 5.12 into Equation 5.5 to give

$$\Delta E = q + w = q - P \Delta V$$
 [5.13]

When a reaction is carried out in a constant-volume container $(\Delta V = 0)$, therefore, the heat transferred equals the change in internal energy:

$$\Delta E = q - P\Delta V = q - P(0) = q_V$$
 (constant volume) [5.14]

The subscript V indicates that the volume is constant.

Most reactions are run under constant pressure, so that Equation 5.13 becomes

$$\Delta E = q_P - P \Delta V$$

$$q_P = \Delta E + P \Delta V \quad \text{(constant pressure)}$$
 [5.15]

We see from Equation 5.9 that the right side of Equation 5.15 is the enthalpy change under constant-pressure conditions. Thus, $\Delta H = q_P$, as we saw in Equation 5.10.

In summary, the change in internal energy is equal to the heat gained or lost at constant volume, and the change in enthalpy is equal to the heat gained or lost at constant pressure. The difference between ΔE and ΔH is the amount of P-V work done by the system when the process occurs at constant pressure, $-P \Delta V$. The volume change accompanying many reactions is close to zero,

which makes $P \Delta V$ and, therefore, the difference between ΔE and ΔH small. Under most circumstances, it is generally satisfactory to use ΔH as the measure of energy changes during most chemical processes.

Related Exercises: 5.35, 5.36, 5.37, 5.38

5.4 | Enthalpies of Reaction

Because $\Delta H = H_{\text{final}} - H_{\text{initial}}$, the enthalpy change for a chemical reaction is given by

$$\Delta H = H_{\text{products}} - H_{\text{reactants}}$$
 [5.16]

The enthalpy change that accompanies a reaction is called either the **enthalpy of reaction** or the *heat of reaction* and is sometimes written ΔH_{rxn} , where "rxn" is a commonly used abbreviation for "reaction."

When we give a numerical value for $\Delta H_{\rm rxn}$, we must specify the reaction involved. For example, when 2 mol $H_2(g)$ burn to form 2 mol $H_2O(g)$ at a constant pressure, the system releases 483.6 kJ of heat. We can summarize this information as

$$2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(g)$$
 $\Delta H = -483.6 \text{ kJ}$ [5.17]

The negative sign for ΔH tells us that this reaction is exothermic. Notice that ΔH is reported at the end of the balanced equation, without explicitly specifying the amounts of chemicals involved. In such cases the coefficients in the balanced equation represent the number of moles of reactants and products producing the associated enthalpy change. Balanced chemical equations that show the associated enthalpy change in this way are called *thermochemical equations*.

The exothermic nature of this reaction is also shown in the *enthalpy diagram* in **Tigure 5.14**. Notice that the enthalpy of the reactants is greater (more positive) than the enthalpy of the products. Thus, $\Delta H = H_{\text{products}} - H_{\text{reactants}}$ is negative.

Give It Some Thought

If the reaction to form water were written $H_2(g) + \frac{1}{2} O_2(g) \longrightarrow H_2O(g)$, would you expect the same value of ΔH as in Equation 5.17? Why or why not?

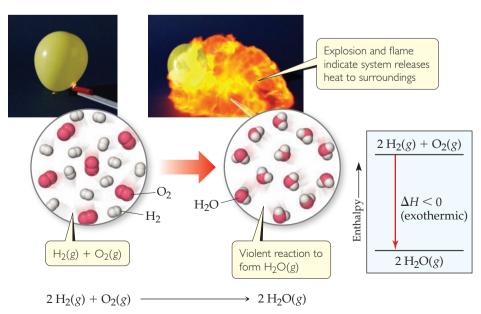

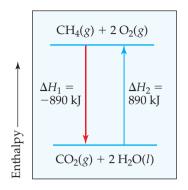

Figure 5.14 Exothermic reaction of hydrogen with oxygen. When a mixture of $H_2(g)$ and $O_2(g)$ is ignited to form $H_2O(g)$, the resultant explosion produces a ball of flame. Because the system releases heat to the surroundings, the reaction is exothermic as indicated in the enthalpy diagram.

► Figure 5.15 ΔH for a reverse reaction. Reversing a reaction changes the sign but not the magnitude of the enthalpy change: $\Delta H_2 = -\Delta H_1$.

The following guidelines are helpful when using thermochemical equations and enthalpy diagrams:

1. Enthalpy is an extensive property. The magnitude of ΔH is proportional to the amount of reactant consumed in the process. For example, 890 kJ of heat is produced when 1 mol of CH₄ is burned in a constant-pressure system:

$$CH_4(g) + 2 O_2(g) \longrightarrow CO_2(g) + 2 H_2O(l)$$
 $\Delta H = -890 \text{ kJ}$ [5.18]

Because the combustion of 1 mol of $\mathrm{CH_4}$ with 2 mol of $\mathrm{O_2}$ releases 890 kJ of heat, the combustion of 2 mol of $\mathrm{CH_4}$ with 4 mol of $\mathrm{O_2}$ releases twice as much heat, 1780 kJ. Although chemical equations are usually written with whole-number coefficients, thermochemical equations sometimes utilize fractions, as in the preceding Give It Some Thought Question.

2. The enthalpy change for a reaction is equal in magnitude, but opposite in sign, to ΔH for the reverse reaction. For example, ΔH for the reverse of Equation 5.18 is +890 kJ:

$$CO_2(g) + 2 H_2O(l) \longrightarrow CH_4(g) + 2 O_2(g)$$
 $\Delta H = +890 \text{ kJ}$ [5.19]

When we reverse a reaction, we reverse the roles of the products and the reactants. From Equation 5.16, we see that reversing the products and reactants leads to the same magnitude of ΔH , but a change in sign (\triangleright Figure 5.15).

3. The enthalpy change for a reaction depends on the states of the reactants and products. If the product in Equation 5.18 were $H_2O(g)$ instead of $H_2O(l)$, $\Delta H_{\rm rxn}$ would be -802 kJ instead of -890 kJ. Less heat would be available for transfer to the surroundings because the enthalpy of $H_2O(g)$ is greater than that of $H_2O(l)$. One way to see this is to imagine that the product is initially liquid water. The liquid water must be converted to water vapor, and the conversion of 2 mol $H_2O(l)$ to 2 mol $H_2O(g)$ is an endothermic process that absorbs 88 kJ:

$$2 \text{ H}_2\text{O}(l) \longrightarrow 2 \text{ H}_2\text{O}(g) \qquad \Delta H = +88 \text{ kJ}$$
 [5.20]

Thus, it is important to specify the states of the reactants and products in thermochemical equations. In addition, we will generally assume that the reactants and products are both at the same temperature, 25 °C, unless otherwise indicated.

SAMPLE EXERCISE 5.5 Relating ΔH to Quantities of Reactants and Products

How much heat is released when 4.50 g of methane gas is burned in a constant-pressure system? (Use the information given in Equation 5.18.)

SOLUTION

Analyze Our goal is to use a thermochemical equation to calculate the heat produced when a specific amount of methane gas is combusted. According to Equation 5.18, 890 kJ is released by the system when 1 mol CH_4 is burned at constant pressure.

Plan Equation 5.18 provides us with a stoichiometric conversion factor: (1 mol $CH_4 \simeq -890$ kJ). Thus, we can convert moles of CH_4 to kJ of energy. First, however, we must convert grams of CH_4 to moles of CH_4 . Thus, the conversion sequence is

Grams
$$CH_4$$
 (given) Molar $Moles CH_4$ Mo

Solve By adding the atomic weights of C and 4 H, we have 1 mol $CH_4 = 16.0 CH_4$. We can use the appropriate conversion factors to convert grams of CH_4 to moles of CH_4 to kilojoules:

Heat =
$$(4.50 \text{ g-CH}_4) \left(\frac{1 \text{ mol-CH}_4}{16.0 \text{ g-CH}_4} \right) \left(\frac{-890 \text{ kJ}}{1 \text{ mol-CH}_4} \right) = -250 \text{ kJ}$$

The negative sign indicates that the system released 250 kJ into the surroundings.

Practice Exercise 1

The complete combustion of ethanol, C_2H_5OH (FW = 46.0 g/mol), proceeds as follows:

$$C_2H_5OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(l)$$
 $\Delta H = -555 \text{ k}$

What is the enthalpy change for combustion of 15.0 g of ethanol?

(a)
$$-12.1 \text{ kJ}$$
 (b) -181 kJ (c) -422 kJ (d) -555 kJ (e) -1700 kJ

Practice Exercise 2

Hydrogen peroxide can decompose to water and oxygen by the reaction

$$2 \text{ H}_2\text{O}_2(l) \longrightarrow 2 \text{ H}_2\text{O}(l) + \text{O}_2(g)$$
 $\Delta H = -196 \text{ kJ}$

Calculate the quantity of heat released when 5.00 g of $H_2O_2(l)$ decomposes at constant pressure.

Strategies in Chemistry

Using Enthalpy as a Guide

If you hold a brick in the air and let it go, you know what happens: It falls as the force of gravity pulls it toward Earth. A process that is thermodynamically favored to happen, such as a brick falling to the ground, is called a *spontaneous* process. A spontaneous process can be either fast or slow; the rate at which processes occur is not governed by thermodynamics.

Chemical processes can be thermodynamically favored, or spontaneous, too. By spontaneous, however, we do not mean that the reaction will form products without any intervention. That can be the case, but often some energy must be imparted to get the process started. The enthalpy change in a reaction gives one indication as to whether the reaction is likely to be spontaneous. The combustion of $H_2(g)$ and $O_2(g)$, for example, is highly exothermic:

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)$$
 $\Delta H = -242 \text{ kJ}$

Hydrogen gas and oxygen gas can exist together in a volume indefinitely without noticeable reaction occurring. Once the reaction is initiated, however, energy is rapidly transferred from the system (the reactants) to the surroundings as heat. The system thus loses enthalpy by transferring the heat to the surroundings. (Recall that the first law of thermodynamics tells us that the total energy of the system plus the surroundings does not change; energy is conserved.)

Enthalpy change is not the only consideration in the spontaneity of reactions, however, nor is it a foolproof guide. For example, even though ice melting is an endothermic process,

$$H_2O(s) \longrightarrow H_2O(l)$$
 $\Delta H = +6.01 \text{ kJ}$

this process is spontaneous at temperatures above the freezing point of water (0 °C). The reverse process, water freezing, is spontaneous at temperatures below 0 °C. Thus, we know that ice at room temperature melts and water put into a freezer at $-20\,^{\circ}\text{C}$ turns into ice. Both processes are spontaneous under different conditions even though they are the reverse of one another. In Chapter 19 we will address the spontaneity of processes more fully. We will see why a process can be spontaneous at one temperature but not at another, as is the case for the conversion of water to ice.

Despite these complicating factors, you should pay attention to the enthalpy changes in reactions. As a general observation, when the enthalpy change is large, it is the dominant factor in determining spontaneity. Thus, reactions for which ΔH is large (about 100 kJ or more) and negative tend to be spontaneous. Reactions for which ΔH is large and positive tend to be spontaneous only in the reverse direction.

Related Exercises: 5.47, 5.48

In many situations we will find it valuable to know the sign and magnitude of the enthalpy change associated with a given chemical process. As we see in the following sections, ΔH can be either determined directly by experiment or calculated from known enthalpy changes of other reactions.

5.5 | Calorimetry

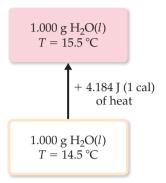

The value of ΔH can be determined experimentally by measuring the heat flow accompanying a reaction at constant pressure. Typically, we can determine the magnitude of the heat flow by measuring the magnitude of the temperature change the heat flow produces. The measurement of heat flow is **calorimetry**; a device used to measure heat flow is a **calorimeter**.

Heat Capacity and Specific Heat

The more heat an object gains, the hotter it gets. All substances change temperature when they are heated, but the magnitude of the temperature change produced by a given quantity of heat varies from substance to substance. The temperature change experienced by an object when it absorbs a certain amount of heat is determined by its

Is the process shown in the figure endothermic or exothermic?

▲ Figure 5.16 Specific heat of water.

heat capacity, denoted *C*. The heat capacity of an object is the amount of heat required to raise its temperature by 1 K (or 1 °C). The greater the heat capacity, the greater the heat required to produce a given increase in temperature.

For pure substances the heat capacity is usually given for a specified amount of the substance. The heat capacity of one mole of a substance is called its **molar heat capacity**, $C_{\rm m}$. The heat capacity of one gram of a substance is called its *specific heat capacity*, or merely its **specific heat**, $C_{\rm s}$. The specific heat, $C_{\rm s}$, of a substance can be determined experimentally by measuring the temperature change, ΔT , that a known mass m of the substance undergoes when it gains or loses a specific quantity of heat q:

Specific heat
$$= \frac{\text{(quantity of heat transferred)}}{\text{(grams of substance)} \times \text{(temperature change)}}$$

$$C_{\text{s}} = \frac{q}{m \times \Delta T}$$
 [5.21]

For example, 209 J is required to increase the temperature of 50.0 g of water by 1.00 K. Thus, the specific heat of water is

$$C_{\rm s} = \frac{209 \,\rm J}{(50.0 \,\rm g)(1.00 \,\rm K)} = 4.18 \,\rm J/g\text{-}K$$

Notice how the units combine in the calculation. A temperature change in kelvins is equal in magnitude to the temperature change in degrees Celsius: ΔT in $K = \Delta T$ in °C. ∞ (Section 1.4) Therefore, this specific heat for water can also be reported as 4.18 J/g-°C, where the unit is pronounced "Joules per gram-degree Celsius."

Because the specific heat values for a given substance can vary slightly with temperature, the temperature is often precisely specified. The 4.18 J/g-K value we use here for water, for instance, is for water initially at $14.5\,^{\circ}$ C (\blacktriangle Figure 5.16). Water's specific heat at this temperature is used to define the calorie at the value given in Section 5.1: 1 cal = 4.184 J exactly.

When a sample absorbs heat (positive q), its temperature increases (positive ΔT). Rearranging Equation 5.21, we get

$$q = C_{\rm s} \times m \times \Delta T \tag{5.22}$$

Thus, we can calculate the quantity of heat a substance gains or loses by using its specific heat together with its measured mass and temperature change.

▼ Table 5.2 lists the specific heats of several substances. Notice that the specific heat of liquid water is higher than those of the other substances listed. The high specific heat of water affects Earth's climate because it makes the temperatures of the oceans relatively resistant to change.

Give It Some Thought

Which substance in Table 5.2 undergoes the greatest temperature change when the same mass of each substance absorbs the same quantity of heat?

Table 5.2 Specific Heats of Some Substances at 298 K

Elements			Compounds		
Substance	Specific Heat (J/g-K)	Substance	Specific Heat (J/g-K)		
$N_2(g)$	1.04	$H_2O(l)$	4.18		
Al(s)	0.90	$CH_4(g)$	2.20		
Fe(s)	0.45	$CO_2(g)$	0.84		
Hg(l)	0.14	$CaCO_3(s)$	0.82		

SAMPLE EXERCISE 5.6

Relating Heat, Temperature Change, and Heat Capacity

(a) How much heat is needed to warm 250 g of water (about 1 cup) from 22 °C (about room temperature) to 98 °C (near its boiling point)? (b) What is the molar heat capacity of water?

SOLUTION

Analyze In part (a) we must find the quantity of heat (q) needed to warm the water, given the mass of water (m), its temperature change (ΔT) , and its specific heat (C_s) . In part (\mathbf{b}) we must calculate the molar heat capacity (heat capacity per mole, $C_{\rm m}$) of water from its specific heat (heat capacity per gram).

Plan (a) Given C_s , m, and ΔT , we can calculate the quantity of heat, q, using Equation 5.22. (b) We can use the molar mass of water and dimensional analysis to convert from heat capacity per gram to heat capacity per mole.

Solve

(a) The water undergoes a temperature change of

Using Equation 5.22, we have

(b) The molar heat capacity is the heat capacity of one mole of substance. Using the atomic weights of hydrogen and oxygen, we have

From the specific heat given in part (a), we have

$$\Delta T = 98 \,^{\circ}\text{C} - 22 \,^{\circ}\text{C} = 76 \,^{\circ}\text{C} = 76 \,^{\circ}\text{K}$$

$$q = C_s \times m \times \Delta T$$

= $(4.18 \text{ J/g-K})(250 \text{ g})(76 \text{ K}) = 7.9 \times 10^4 \text{ J}$

 $1 \text{ mol H}_2\text{O} = 18.0 \text{ g H}_2\text{O}$

$$C_{\rm m} = \left(4.18 \frac{\rm J}{\rm g-K}\right) \left(\frac{18.0 \text{ g}}{1 \text{ mol}}\right) = 75.2 \text{ J/mol-K}$$

Practice Exercise 1

Suppose you have equal masses of two substances, A and B. When the same amount of heat is added to samples of each, the temperature of A increases by 14 °C whereas that of B increases by 22 °C. Which of the following statements is true? (a) The heat capacity of B is greater than that of A. (b) The specific heat of A is greater than that of B. (c) The molar heat capacity of B is greater than that of A. (d) The volume of A is greater than that of B. (e) The molar mass of A is greater than that of B.

Practice Exercise 2

(a) Large beds of rocks are used in some solar-heated homes to store heat. Assume that the specific heat of the rocks is 0.82 J/g-K. Calculate the quantity of heat absorbed by 50.0 kg of rocks if their temperature increases by 12.0 °C. (b) What temperature change would these rocks undergo if they emitted 450 kJ of heat?

Constant-Pressure Calorimetry

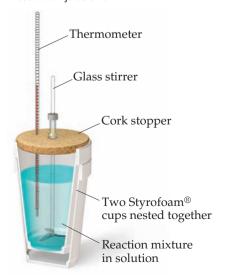

The techniques and equipment employed in calorimetry depend on the nature of the process being studied. For many reactions, such as those occurring in solution, it is easy to control pressure so that ΔH is measured directly. Although the calorimeters used for highly accurate work are precision instruments, a simple "coffee-cup" calorimeter (> Figure 5.17) is often used in general chemistry laboratories to illustrate the principles of calorimetry. Because the calorimeter is not sealed, the reaction occurs under the essentially constant pressure of the atmosphere.

Imagine adding two aqueous solutions, each containing a reactant, to a coffee-cup calorimeter. Once mixed, a reaction occurs. In this case there is no physical boundary between the system and the surroundings. The reactants and products of the reaction are the system, and the water in which they are dissolved is part of the surroundings. (The calorimeter apparatus is also part of the surroundings.) If we assume that the calorimeter is perfectly insulated, then any heat released or absorbed by the reaction will raise or lower the temperature of the water in the solution. Thus, we measure the temperature change of the solution and assume that any changes are due to heat transferred from the reaction to the water (for an exothermic process) or transferred from

Go Figure

Propose a reason for why two Styrofoam® cups are often used instead of just one.

▲ Figure 5.17 Coffee-cup calorimeter.

This simple apparatus is used to measure temperature changes of reactions at constant pressure.

the water to the reaction (endothermic). In other words, by monitoring the temperature of the solution, we are seeing the flow of heat between the system (the reactants and products in the solution) and the surroundings (the water that forms the bulk of the solution).

For an exothermic reaction, heat is "lost" by the reaction and "gained" by the water in the solution, so the temperature of the solution rises. The opposite occurs for an endothermic reaction: Heat is gained by the reaction and lost by the water in the solution, and the temperature of the solution decreases. The heat gained or lost by the solution, $q_{\rm soln}$, is therefore equal in magnitude but opposite in sign to the heat absorbed or released by the reaction, $q_{\rm rxn}$: $q_{\rm soln} = -q_{\rm rxn}$. The value of $q_{\rm soln}$ is readily calculated from the mass of the solution, its specific heat, and the temperature change:

$$q_{\rm soln} = (\text{specific heat of solution}) \times (\text{grams of solution}) \times \Delta T = -q_{\rm rxn}$$
 [5.23]

For dilute aqueous solutions we usually assume that the specific heat of the solution is the same as that of water, 4.18 J/g-K.

Equation 5.23 makes it possible to calculate $q_{\rm rxn}$ from the temperature change of the solution in which the reaction occurs. A temperature increase ($\Delta T > 0$) means the reaction is exothermic ($q_{\rm rxn} < 0$).

SAMPLE EXERCISE 5.7 Measuring ΔH Using a Coffee-Cup Calorimeter

When a student mixes 50 mL of 1.0 M HCl and 50 mL of 1.0 M NaOH in a coffee-cup calorimeter, the temperature of the resultant solution increases from 21.0 to 27.5 °C. Calculate the enthalpy change for the reaction in kJ/mol HCl, assuming that the calorimeter loses only a negligible quantity of heat, that the total volume of the solution is 100 mL, that its density is $1.0 \, \text{g/mL}$, and that its specific heat is $4.18 \, \text{J/g-K}$.

SOLUTION

Analyze Mixing solutions of HCl and NaOH results in an acid-base reaction:

$$HCl(aq) + NaOH(aq) \longrightarrow H_2O(l) + NaCl(aq)$$

We need to calculate the heat produced per mole of HCl, given the temperature increase of the solution, the number of moles of HCl and NaOH involved, and the density and specific heat of the solution.

Plan The total heat produced can be calculated using Equation 5.23. The number of moles of HCl consumed in the reaction must be calculated from the volume and molarity of this substance, and this amount is then used to determine the heat produced per mol HCl.

Solve

Because the total volume of the solution is 100 mL, its mass is

The temperature change is Using Equation 5.23, we have

Because the process occurs at constant pressure,

 $(100\,mL)(1.0\,g/mL)\,=\,100\,g$

 $\Delta T = 27.5 \,^{\circ}\text{C} - 21.0 \,^{\circ}\text{C} = 6.5 \,^{\circ}\text{C} = 6.5 \,^{\circ}\text{K}$

 $q_{\rm rxn} = -C_{\rm s} \times m \times \Delta T$

 $= -(4.18 \,\mathrm{J/g} - \mathrm{K})(100 \,\mathrm{g})(6.5 \,\mathrm{K}) = -2.7 \times 10^3 \,\mathrm{J} = -2.7 \,\mathrm{kJ}$

 $\Delta H = q_P = -2.7 \text{ kJ}$

To express the enthalpy change on a molar basis, we use the fact that the number of moles of HCl is given by the product of the volume (50 mL = 0.050 L) and concentration (1.0 M = 1.0 mol/L) of the HCl solution:

 $(0.050 \,\mathrm{L})(1.0 \,\mathrm{mol/L}) = 0.050 \,\mathrm{mol}$

Thus, the enthalpy change per mole of HCl is

 $\Delta H = -2.7 \,\text{kJ}/0.050 \,\text{mol} = -54 \,\text{kJ/mol}$

Check ΔH is negative (exothermic), as evidenced by the observed increase in the temperature. The magnitude of the molar enthalpy change seems reasonable.

Practice Exercise 1

When 0.243~g of Mg metal is combined with enough HCl to make 100~mL of solution in a constant-pressure calorimeter, the following reaction occurs:

$$Mg(s) + 2 HCl(aq) \longrightarrow MgCl_2(aq) + H_2(g)$$

If the temperature of the solution increases from 23.0 to 34.1 °C as a result of this reaction, calculate ΔH in kJ/mol Mg. Assume that the solution has a specific heat of 4.18 J/g-°C. (a) -19.1 kJ/mol (b) -111 kJ/mol (c) -191 kJ/mol (d) -464 kJ/mol (e) -961 kJ/mol

Practice Exercise 2

When 50.0 mL of 0.100 M AgNO₃ and 50.0 mL of 0.100 M HCl are mixed in a constantpressure calorimeter, the temperature of the mixture increases from 22.30 to 23.11 °C. The temperature increase is caused by the following reaction:

$$AgNO_3(aq) + HCl(aq) \longrightarrow AgCl(s) + HNO_3(aq)$$

Calculate ΔH for this reaction in kJ/mol AgNO₃, assuming that the combined solution has a mass of 100.0 g and a specific heat of 4.18 J/g-°C.

Bomb Calorimetry (Constant-Volume Calorimetry)

An important type of reaction studied using calorimetry is combustion, in which a compound reacts completely with excess oxygen. compound (Section 3.2) Combustion reactions are most accurately studied using a bomb calorimeter (> Figure 5.18). The substance to be studied is placed in a small cup within an insulated sealed vessel called a bomb. The bomb, which is designed to withstand high pressures, has an inlet valve for adding oxygen and electrical leads for initiating the reaction. After the sample has been placed in the bomb, the bomb is sealed and pressurized with oxygen. It is then placed in the calorimeter and covered with an accurately measured quantity of water. The combustion reaction is initiated by passing an electrical current through a fine wire in contact with the sample. When the wire becomes sufficiently hot, the sample ignites.

The heat released when combustion occurs is absorbed by the water and the various components of the calorimeter (which all together make up the surroundings), causing the water temperature to rise. The change in water temperature caused by the reaction is measured very precisely.

To calculate the heat of combustion from the measured temperature increase, we must know the total heat capacity of the calorimeter, C_{cal} . This quantity is determined by combusting a sample that releases a known quantity of heat and measuring the temperature change. For example, combustion of exactly 1 g of benzoic acid, C₆H₅COOH, in a bomb calorimeter produces 26.38 kJ of heat. Suppose 1.000 g of benzoic acid is combusted in a calorimeter, leading to a temperature increase of 4.857 °C. The heat capacity of the calorimeter is then $C_{cal} = 26.38 \text{ kJ}/4.857 \,^{\circ}\text{C} = 5.431 \,\text{kJ}/^{\circ}\text{C}$. Once we know C_{cal} , we can measure temperature changes produced by other reactions, and from these we can calculate the heat evolved in the reaction, q_{rxn} :

$$q_{\rm ryp} = -C_{\rm cal} \times \Delta T \tag{5.24}$$

$q_{\rm rxn} = -C_{\rm cal} \times \Delta T$ [5.24]

SAMPLE EXERCISE 5.8 Measuring q_{rxn} Using a Bomb Calorimeter

The combustion of methylhydrazine (CH_6N_2), a liquid rocket fuel, produces $N_2(g)$, $CO_2(g)$, and $H_2O(l)$:

$$2 \text{ CH}_6 \text{N}_2(l) + 5 \text{ O}_2(g) \longrightarrow 2 \text{ N}_2(g) + 2 \text{ CO}_2(g) + 6 \text{ H}_2 \text{O}(l)$$

When 4.00 g of methylhydrazine is combusted in a bomb calorimeter, the temperature of the calorimeter increases from 25.00 to 39.50 °C. In a separate experiment the heat capacity of the calorimeter is measured to be 7.794 kJ/°C. Calculate the heat of reaction for the combustion of a mole of CH₆N₂.

SOLUTION

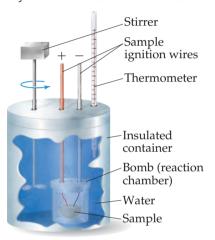

Analyze We are given a temperature change and the total heat capacity of the calorimeter. We are also given the amount of reactant combusted. Our goal is to calculate the enthalpy change per mole for combustion of the reactant.

Plan We will first calculate the heat evolved for the combustion of the 4.00-g sample. We will then convert this heat to a molar quantity.

GO FIGURE

Why is a stirrer used in calorimeters?

▲ Figure 5.18 Bomb calorimeter.

Solve

For combustion of the 4.00-g sample of methylhydrazine, the temperature change of the calorimeter is

We can use ΔT and the value for $C_{\rm cal}$ to calculate the heat of reaction (Equation 5.24):

We can readily convert this value to the heat of reaction for a mole of CH_6N_2 :

$$\Delta T = (39.50 \,^{\circ}\text{C} - 25.00 \,^{\circ}\text{C}) = 14.50 \,^{\circ}\text{C}$$

$$q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T = -(7.794 \,\text{kJ/°C})(14.50 \,^{\circ}\text{C}) = -113.0 \,\text{kJ}$$

$$\left(\frac{-113.0\,\text{kJ}}{4.00\,\text{g-CH}_6\text{N}_2}\right) \times \left(\frac{46.1\,\text{g-CH}_6\text{N}_2}{1\,\text{mol CH}_6\text{N}_2}\right) = -1.30\,\times\,10^3\,\text{kJ/mol CH}_6\text{N}_2$$

Check The units cancel properly, and the sign of the answer is negative as it should be for an exothermic reaction. The magnitude of the answer seems reasonable.

Practice Exercise 1

The combustion of exactly 1.000 g of benzoic acid in a bomb calorimeter releases 26.38 kJ of heat. If the combustion of 0.550 g of benzoic acid causes the temperature of the calorimeter to increase from 22.01 to 24.27 °C, calculate the heat capacity of the calorimeter. (a) 0.660 kJ/°C (b) $6.42 \, \text{kJ/°C}$ (c) $14.5 \, \text{kJ/°C}$ (d) $21.2 \, \text{kJ/g-°C}$ (e) $32.7 \, \text{kJ/°C}$

Practice Exercise 2

A 0.5865-g sample of lactic acid ($HC_3H_5O_3$) is burned in a calorimeter whose heat capacity is 4.812 kJ/ $^{\circ}$ C. The temperature increases from 23.10 to 24.95 $^{\circ}$ C. Calculate the heat of combustion of lactic acid (**a**) per gram and (**b**) per mole.

Because reactions in a bomb calorimeter are carried out at constant volume, the heat transferred corresponds to the change in internal energy, ΔE , rather than the change in enthalpy, ΔH (Equation 5.14). For most reactions, however, the difference between ΔE and ΔH is very small. For the reaction discussed in Sample Exercise 5.8, for example, the difference between ΔE and ΔH is about 1 kJ/mol—a difference of less than 0.1%. It is possible to calculate ΔH from ΔE , but we need not concern ourselves with how these small corrections are made.

Chemistry and Life

The Regulation of Body Temperature

For most of us, being asked the question "Are you running a fever?" was one of our first introductions to medical diagnosis. Indeed, a deviation in body temperature of only a few degrees indicates something amiss. Maintaining a near-constant temperature is one of the primary physiological functions of the human body.

To understand how the body's heating and cooling mechanisms operate, we can view the body as a thermodynamic system. The body increases its internal energy content by ingesting foods from the surroundings. The foods, such as glucose ($C_6H_{12}O_6$), are metabolized—a process that is essentially controlled oxidation to CO_2 and H_2O :

$$C_6H_{12}O_6(s) + 6 O_2(g) \longrightarrow 6 CO_2(g) + 6 H_2O(l)$$

 $\Delta H = -2803 \text{ kJ}$

Roughly 40% of the energy produced is ultimately used to do work in the form of muscle contractions and nerve cell activities. The remainder is released as heat, part of which is used to maintain body temperature. When the body produces too much heat, as in times of heavy physical exertion, it dissipates the excess to the surroundings.

Heat is transferred from the body to its surroundings primarily by *radiation*, *convection*, and *evaporation*. Radiation is the direct loss of heat from the body to cooler surroundings, much as a hot stovetop radiates heat to its surroundings. Convection is heat loss by virtue of heating air that is in contact with the body. The heated air rises and is replaced with cooler air, and the process continues.

Warm clothing decreases convective heat loss in cold weather. Evaporative cooling occurs when perspiration is generated at the skin surface by the sweat glands (▼ Figure 5.19). Heat is removed from the body as the perspiration evaporates. Perspiration is predominantly water, so the process is the endothermic conversion of liquid water into water vapor:

$$H_2O(l) \longrightarrow H_2O(g)$$
 $\Delta H = +44.0 \text{ kJ}$

The speed with which evaporative cooling occurs decreases as the atmospheric humidity increases, which is why we feel more sweaty and uncomfortable on hot, humid days.

When body temperature becomes too high, heat loss increases in two principal ways. First, blood flow near the skin surface increases, which allows for increased radiational and convective cooling. The reddish, "flushed" appearance of a hot individual is due to this increased blood flow. Second, we sweat, which increases evaporative

▲ Figure 5.19 Perspiration.

cooling. During extreme activity, the amount of perspiration can be as high as 2 to 4 liters per hour. As a result, the body's water supply must be replenished during these periods. If the body loses too much liquid through perspiration, it will no longer be able to cool itself and blood volume decreases, which can lead to either *heat exhaustion* or the more serious *heat stroke*. However, replenishing water without replenishing the electrolytes lost during perspiration can also lead to serious problems. If the normal blood sodium level drops too low, dizziness and confusion set in, and the condition can become critical.

Drinking a sport drink that contains some electrolytes helps to prevent this problem.

When body temperature drops too low, blood flow to the skin surface decreases, thereby decreasing heat loss. The lower temperature also triggers small involuntary contractions of the muscles (shivering); the biochemical reactions that generate the energy to do this work also generate heat for the body. If the body is unable to maintain a normal temperature, the very dangerous condition called *hypothermia* can result.

5.6 | Hess's Law

It is often possible to calculate the ΔH for a reaction from the tabulated ΔH values of other reactions. Thus, it is not necessary to make calorimetric measurements for all reactions.

Because enthalpy is a state function, the enthalpy change, ΔH , associated with any chemical process depends only on the amount of matter that undergoes change and on the nature of the initial state of the reactants and the final state of the products. This means that whether a particular reaction is carried out in one step or in a series of steps, the sum of the enthalpy changes associated with the individual steps must be the same as the enthalpy change associated with the one-step process. As an example, combustion of methane gas, $\operatorname{CH}_4(g)$, to form $\operatorname{CO}_2(g)$ and $\operatorname{H}_2\operatorname{O}(l)$ can be thought of as occurring in one step, as represented on the left in \triangleright Figure 5.20, or in two steps, as represented on the right in Figure 5.20: (1) combustion of $\operatorname{CH}_4(g)$ to form $\operatorname{CO}_2(g)$ and $\operatorname{H}_2\operatorname{O}(g)$ and (2) condensation of $\operatorname{H}_2\operatorname{O}(g)$ to form $\operatorname{H}_2\operatorname{O}(l)$. The enthalpy change for the overall process is the sum of the enthalpy changes for these two steps:

$$CH_4(g) + 2 O_2(g) \longrightarrow CO_2(g) + 2 H_2O(g) \qquad \Delta H = -802 \text{ kJ}$$

$$(Add) \qquad \qquad 2 H_2O(g) \longrightarrow 2 H_2O(l) \qquad \Delta H = -88 \text{ kJ}$$

$$CH_4(g) + 2 O_2(g) + 2 H_2O(g) \longrightarrow CO_2(g) + 2 H_2O(l) + 2 H_2O(g)$$

The net equation is

$$CH_4(g) + 2 O_2(g) \longrightarrow CO_2(g) + 2 H_2O(l) \Delta H = -890 \text{ kJ}$$

Hess's law states that if a reaction is carried out in a series of steps, ΔH for the overall reaction equals the sum of the enthalpy changes for the individual steps. The overall enthalpy change for the process is independent of the number of steps and independent of the path by which the reaction is carried out. This law is a consequence of the fact that enthalpy is a state function. We can therefore calculate ΔH for any process as long as we find a route for which ΔH is known for each step. This means that a relatively small number of experimental measurements can be used to calculate ΔH for a vast number of reactions.

Hess's law provides a useful means of calculating energy changes that are difficult to measure directly. For instance, it is impossible to measure directly the enthalpy for the combustion of carbon to form carbon monoxide. Combustion of 1 mol of carbon with 0.5 mol of $\rm O_2$ produces both CO and $\rm CO_2$, leaving some carbon unreacted. However, solid carbon and carbon monoxide can both be completely burned in $\rm O_2$ to produce $\rm CO_2$. We can therefore use the enthalpy changes of these reactions to calculate the heat of combustion of carbon.

Give It Some Thought

What effect do these changes have on ΔH for a reaction:

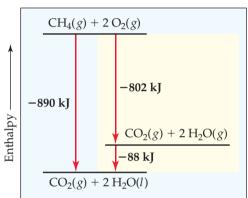

- (a) Reversing the reaction
- (b) Multiplying the coefficients of the equation for the reaction by 2?

 $\Delta H = -890 \, \text{kJ}$

GO FIGURE

What process corresponds to the -88 kJ enthalpy change?

► Figure 5.20 Enthalpy diagram for combustion of 1 mol of methane. The enthalpy change of the one-step reaction equals the sum of the enthalpy changes of the reaction run in two steps: -890 kJ = -802 kJ + (-88 kJ).

SAMPLE EXERCISE 5.9 Using Hess's Law to Calculate ΔH

The enthalpy of reaction for the combustion of C to CO_2 is -393.5 kJ/mol C, and the enthalpy for the combustion of CO to CO_2 is -283.0 kJ/mol CO:

(1)
$$C(s) + O_2(g) \longrightarrow CO_2(g)$$
 $\Delta H = -393.5 \text{ kJ}$

(2)
$$CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$$
 $\Delta H = -283.0 \text{ kJ}$

Using these data, calculate the enthalpy for the combustion of C to CO:

(3)
$$C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g)$$
 $\Delta H = ?$

SOLUTION

Analyze We are given two thermochemical equations, and our goal is to combine them in such a way as to obtain the third equation and its enthalpy change.

Plan We will use Hess's law. In doing so, we first note the numbers of moles of substances among the reactants and products in the target equation (3). We then manipulate equations (1) and (2) to give the same number of moles of these substances, so that when the resulting equations are added, we obtain the target equation. At the same time, we keep track of the enthalpy changes, which we add.

Solve To use equations (1) and (2), we arrange them so that C(s) is on the reactant side and CO(g) is on the product side of the arrow, as in the target reaction, equation (3). Because equation (1) has C(s) as a reactant, we can use that equation just as it is. We need to turn equation (2) around, however, so that CO(g) is a product. Remember that when reactions are turned around, the sign of ΔH is reversed. We arrange the two equations so that they can be added to give the desired equation:

$$C(s) + O_2(g) \longrightarrow CO_2(g) \qquad \Delta H = -393.5 \text{ kJ}$$

$$CO_2(g) \longrightarrow CO(g) + \frac{1}{2}O_2(g) \qquad -\Delta H = 283.0 \text{ kJ}$$

$$C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta H = -110.5 \text{ kJ}$$

When we add the two equations, $CO_2(g)$ appears on both sides of the arrow and therefore cancels out. Likewise, $\frac{1}{2}O_2(g)$ is eliminated from each side.

Practice Exercise 1

Calculate ΔH for $2NO(g) + O_2(g) \longrightarrow N_2O_4(g)$, using the following information:

$$N_2O_4(g) \longrightarrow 2NO_2(g) \quad \Delta H = +57.9 \text{ kJ}$$

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g) \quad \Delta H = -113.1 \text{ kJ}$$
(a) 2.7 kJ (b) -55.2 kJ (c) -85.5 kJ (d) -171.0 kJ (e) +55.2 kJ

Practice Exercise 2

Carbon occurs in two forms, graphite and diamond. The enthalpy of the combustion of graphite is -393.5 kJ/mol, and that of diamond is -395.4 kJ/mol:

$$C(graphite) + O_2(g) \longrightarrow CO_2(g)$$
 $\Delta H = -393.5 \text{ kJ}$
 $C(diamond) + O_2(g) \longrightarrow CO_2(g)$ $\Delta H = -395.4 \text{ kJ}$

Calculate ΔH for the conversion of graphite to diamond:

$$C(graphite) \longrightarrow C(diamond) \Delta H = ?$$

SAMPLE EXERCISE 5.10 Using Three Equations with Hess's Law to Calculate ΔH

Calculate ΔH for the reaction

$$2 C(s) + H_2(g) \longrightarrow C_2H_2(g)$$

given the following chemical equations and their respective enthalpy changes:

$$\begin{array}{lll} \mathrm{C_2H_2}(g) \ + \ \frac{5}{2}\mathrm{O_2}(g) & \longrightarrow & 2\,\mathrm{CO_2}(g) \ + \ \mathrm{H_2O}(l) & \Delta H = -1299.6\,\mathrm{kJ} \\ \mathrm{C}(s) \ + \ \mathrm{O_2}(g) & \longrightarrow & \mathrm{CO_2}(g) & \Delta H = -393.5\,\mathrm{kJ} \\ \mathrm{H_2}(g) \ + \ \frac{1}{2}\mathrm{O_2}(g) & \longrightarrow & \mathrm{H_2O}(l) & \Delta H = -285.8\,\mathrm{kJ} \end{array}$$

SOLUTION

Analyze We are given a chemical equation and asked to calculate its ΔH using three chemical equations and their associated enthalpy changes.

Plan We will use Hess's law, summing the three equations or their reverses and multiplying each by an appropriate coefficient so that they add to give the net equation for the reaction of interest. At the same time, we keep track of the ΔH values, reversing their signs if the reactions are reversed and multiplying them by whatever coefficient is employed in the equation.

Solve Because the target equation has C_2H_2 as a product, we turn the first equation around; the sign of ΔH is therefore changed. The desired equation has $2\ C(s)$ as a reactant, so we multiply the second equation and its ΔH by 2. Because the target equation has H_2 as a reactant, we keep the third equation as it is. We then add the three equations and their enthalpy changes in accordance with Hess's law:

$$2C\Theta_{2}(g) + H_{2}O(l) \longrightarrow C_{2}H_{2}(g) + \frac{5}{2}\Theta_{2}(g) \qquad \Delta H = 1299.6 \text{ kJ}$$

$$2C(s) + 2\Theta_{2}(g) \longrightarrow 2C\Theta_{2}(g) \qquad \Delta H = -787.0 \text{ kJ}$$

$$H_{2}(g) + \frac{1}{2}\Theta_{2}(g) \longrightarrow H_{2}O(l) \qquad \Delta H = -285.8 \text{ kJ}$$

$$2C(s) + H_{2}(g) \longrightarrow C_{2}H_{2}(g) \qquad \Delta H = 226.8 \text{ kJ}$$

When the equations are added, there are $2 CO_2, \frac{5}{2} O_2$, and H_2O on both sides of the arrow. These are canceled in writing the net equation.

Check The procedure must be correct because we obtained the correct net equation. In cases like this you should go back over the numerical manipulations of the ΔH values to ensure that you did not make an inadvertent error with signs.

Practice Exercise 1

We can calculate ΔH for the reaction

$$C(s) + H_2O(g) \longrightarrow CO(g) + H_2(g)$$

using the following thermochemical equations:

$$C(s) + O_2(g) \longrightarrow CO_2(g)$$
 $\Delta H_1 = -393.5 \text{ kJ}$
 $2 CO(g) + O_2(g) \longrightarrow 2 CO_2(g)$ $\Delta H_2 = -566.0 \text{ kJ}$
 $2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(g)$ $\Delta H_3 = -483.6 \text{ kJ}$

By what coefficient do you need to multiply ΔH_2 in determining ΔH for the target equation? (a) -1/2 (b) -1 (c) -2 (d) 1/2 (e) 2

Practice Exercise 2

Calculate ΔH for the reaction

$$NO(g) + O(g) \longrightarrow NO_2(g)$$

given the following information:

$$NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g)$$
 $\Delta H = -198.9 \text{ kJ}$
 $O_3(g) \longrightarrow \frac{3}{2} O_2(g)$ $\Delta H = -142.3 \text{ kJ}$
 $O_2(g) \longrightarrow 2 O(g)$ $\Delta H = 495.0 \text{ kJ}$

The key point of these examples is that H is a state function, so for a particular set of reactants and products, ΔH is the same whether the reaction takes place in one step or in a series of steps. We reinforce this point by giving one more example of an enthalpy diagram and Hess's law. Again we use combustion of methane to form CO_2 and H_2O , our reaction from Figure 5.20. This time we envision a different two-step path, with the initial formation of CO, which is then combusted to CO_2 (\blacktriangleright Figure 5.21). Even though the two-step path is different from that in Figure 5.20, the overall reaction again has $\Delta H_1 = -890$ kJ. Because H is a state function, both paths must produce the same value of ΔH . In Figure 5.21, that means $\Delta H_1 = \Delta H_2 + \Delta H_3$. We will soon see that breaking up reactions in this way allows us to derive the enthalpy changes for reactions that are hard to carry out in the laboratory.

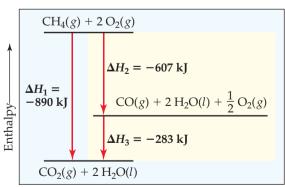

5.7 | Enthalpies of Formation

We can use the methods just discussed to calculate enthalpy changes for a great many reactions from tabulated ΔH values. For example, extensive tables exist of *enthalpies of vaporization* (ΔH for converting liquids to gases), *enthalpies of fusion* (ΔH for melting solids),

GO FIGURE

Suppose the overall reaction were modified to produce 2 $H_2O(g)$ rather than 2 $H_2O(I)$. Would any of the values of ΔH in the diagram stay the same?

▲ Figure 5.21 Enthalpy diagram illustrating Hess's law. The net reaction is the same as in Figure 5.20, but here we imagine different reactions in our two-step version. As long as we can write a series of equations that add up to the equation we need, and as long as we know a value for ΔH for all intermediate reactions, we can calculate the overall ΔH .

enthalpies of combustion (ΔH for combusting a substance in oxygen), and so forth. A particularly important process used for tabulating thermochemical data is the formation of a compound from its constituent elements. The enthalpy change associated with this process is called the **enthalpy of formation** (or *heat of formation*), ΔH_f , where the subscript f indicates that the substance has been *formed* from its constituent elements.

The magnitude of any enthalpy change depends on the temperature, pressure, and state (gas, liquid, or solid crystalline form) of the reactants and products. To compare enthalpies of different reactions, we must define a set of conditions, called a **standard state**, at which most enthalpies are tabulated. The standard state of a substance is its pure form at atmospheric pressure (1 atm) and the temperature of interest, which we usually choose to be 298 K (25 °C).* The **standard enthalpy change** of a reaction is defined as the enthalpy change when all reactants and products are in their standard states. We denote a standard enthalpy change as ΔH° , where the superscript $^{\circ}$ indicates standard-state conditions.

The **standard enthalpy of formation** of a compound, ΔH_f° , is the change in enthalpy for the reaction that forms one mole of the compound from its elements with all substances in their standard states:

If: elements (in standard state)
$$\longrightarrow$$
 compound (1 mol in standard state)
Then: $\Delta H = \Delta H_f^{\circ}$

We usually report ΔH_f° values at 298 K. If an element exists in more than one form under standard conditions, the most stable form of the element is usually used for the formation reaction. For example, the standard enthalpy of formation for ethanol, C_2H_5OH , is the enthalpy change for the reaction

$$2 C(graphite) + 3 H_2(g) + \frac{1}{2}O_2(g) \longrightarrow C_2H_5OH(l)$$
 $\Delta H_f^{\circ} = -277.7 \text{ kJ} [5.25]$

The elemental source of oxygen is O_2 , not O or O_3 , because O_2 is the stable form of oxygen at 298 K and atmospheric pressure. Similarly, the elemental source of carbon is graphite and not diamond because graphite is the more stable (lower-energy) form at 298 K and atmospheric pressure. Likewise, the most stable form of hydrogen under standard conditions is $H_2(g)$, so this is used as the source of hydrogen in Equation 5.25.

The stoichiometry of formation reactions always indicates that one mole of the desired substance is produced, as in Equation 5.25. As a result, standard enthalpies of formation are reported in kJ/mol of the substance being formed. Some values are given in \blacksquare Table 5.3, and a more extensive table is provided in Appendix C.

Table 5.3	Standard	Enthalpies	of Formation,	ΔH_f° , at 298 K
			,	,

Substance	Formula	ΔH _f ° (kJ/mol)	Substance	Formula	$\Delta H_f^{\circ}(kJ/mol)$
Acetylene	$C_2H_2(g)$	226.7	Hydrogen chloride	HCl(g)	-92.30
Ammonia	$NH_3(g)$	-46.19	Hydrogen fluoride	HF(g)	-268.60
Benzene	$C_6H_6(l)$	49.0	Hydrogen iodide	HI(g)	25.9
Calcium carbonate	$CaCO_3(s)$	-1207.1	Methane	$CH_4(g)$	-74.80
Calcium oxide	CaO(s)	-635.5	Methanol	$CH_3OH(l)$	-238.6
Carbon dioxide	$CO_2(g)$	-393.5	Propane	$C_3H_8(g)$	-103.85
Carbon monoxide	CO(g)	-110.5	Silver chloride	AgCl(s)	-127.0
Diamond	C(s)	1.88	Sodium bicarbonate	$NaHCO_3(s)$	-947.7
Ethane	$C_2H_6(g)$	-84.68	Sodium carbonate	$Na_2CO_3(s)$	-1130.9
Ethanol	$C_2H_5OH(l)$	-277.7	Sodium chloride	NaCl(s)	-410.9
Ethylene	$C_2H_4(g)$	52.30	Sucrose	$C_{12}H_{22}O_{11}(s)$	-2221
Glucose	$C_6H_{12}O_6(s)$	-1273	Water	$H_2O(l)$	-285.8
Hydrogen bromide	HBr(g)	-36.23	Water vapor	$H_2O(g)$	-241.8

^{*}The definition of the standard state for gases has been changed to 1 bar (1 atm = 1.013 bar), a slightly lower pressure than 1 atm. For most purposes, this change makes very little difference in the standard enthalpy changes.

By definition, the standard enthalpy of formation of the most stable form of any element is zero because there is no formation reaction needed when the element is already in its standard state. Thus, the values of ΔH_f° for C(graphite), $H_2(g)$, $O_2(g)$, and the standard states of other elements are zero by definition.

Give It Some Thought

Ozone, $O_3(g)$, is a form of elemental oxygen produced during electrical discharge. Is ΔH_f° for $O_3(g)$ necessarily zero?

SAMPLE EXERCISE 5.11

Equations Associated with Enthalpies of Formation

For which of these reactions at 25 °C does the enthalpy change represent a standard enthalpy of formation? For each that does not, what changes are needed to make it an equation whose ΔH is an enthalpy of formation?

(a)
$$2 \operatorname{Na}(s) + \frac{1}{2} \operatorname{O}_2(g) \longrightarrow \operatorname{Na}_2 \operatorname{O}(s)$$

(b)
$$2 K(l) + Cl_2(g) \longrightarrow 2 KCl(s)$$

(c)
$$C_6H_{12}O_6(s) \longrightarrow 6 C(diamond) + 6 H_2(g) + 3 O_2(g)$$

SOLUTION

Analyze The standard enthalpy of formation is represented by a reaction in which each reactant is an element in its standard state and the product is one mole of the compound.

Plan We need to examine each equation to determine (1) whether the reaction is one in which one mole of substance is formed from the elements, and (2) whether the reactant elements are in their standard states.

Solve In (a) 1 mol Na_2O is formed from the elements sodium and oxygen in their proper states, solid Na and O_2 gas, respectively. Therefore, the enthalpy change for reaction (a) corresponds to a standard enthalpy of formation.

In (b) potassium is given as a liquid. It must be changed to the solid form, its standard state at room temperature. Furthermore, 2 mol KCI are formed, so the enthalpy change for the reaction as written is twice the standard enthalpy of formation of KCl(s). The equation for the formation reaction of 1 mol of KCl(s) is

$$K(s) + \frac{1}{2}Cl_2(g) \longrightarrow KCl(s)$$

Reaction (c) does not form a substance from its elements. Instead, a substance decomposes to its elements, so this reaction must be reversed. Next, the element carbon is given as diamond, whereas graphite is the standard state of carbon at room temperature and 1 atm pressure. The equation that correctly represents the enthalpy of formation of glucose from its elements is

$$6 C(graphite) + 6 H_2(g) + 3 O_2(g) \longrightarrow C_6 H_{12}O_6(s)$$

Practice Exercise 1

If the heat of formation of $\rm H_2O(\it l)$ is $-286\,\rm kJ/mol$, which of the following thermochemical equations is correct?

(a)
$$2H(g)+O(g) \longrightarrow H_2O(l)$$
 $\Delta H = -286 \text{ kJ}$

(b)
$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$$
 $\Delta H = -286 \text{ kJ}$

(c)
$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l)$$
 $\Delta H = -286 \text{ kJ}$

(d)
$$H_2(g) + O(g) \longrightarrow H_2O(g)$$
 $\Delta H = -286 \text{ kJ}$

(e)
$$H_2O(l) \longrightarrow H_2(g) + \frac{1}{2}O_2(g)$$
 $\Delta H = -286 \text{ kJ}$

Practice Exercise 2

Write the equation corresponding to the standard enthalpy of formation of liquid carbon tetrachloride (CCl₄) and look up ΔH_f° for this compound in Appendix C.

Using Enthalpies of Formation to Calculate Enthalpies of Reaction

We can use Hess's law and tabulations of ΔH_f° values, such as those in Table 5.3 and Appendix C, to calculate the standard enthalpy change for any reaction for which we know the ΔH_f° values for all reactants and products. For example, consider the combustion of propane under standard conditions:

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(l)$$

We can write this equation as the sum of three equations associated with standard enthalpies of formation:

$$C_{3}H_{8}(g) \longrightarrow 3 C(s) + 4 H_{2}(g) \qquad \Delta H_{1} = -\Delta H_{f}^{\circ}[C_{3}H_{8}(g)] \quad [5.26]$$

$$3 C(s) + 3 O_{2}(g) \longrightarrow 3 CO_{2}(g) \qquad \Delta H_{2} = 3\Delta H_{f}^{\circ}[CO_{2}(g)] \quad [5.27]$$

$$\frac{4 H_{2}(g) + 2 O_{2}(g) \longrightarrow 4 H_{2}O(l) \qquad \Delta H_{3} = 4\Delta H_{f}^{\circ}[H_{2}O(l)] \quad [5.28]}{C_{3}H_{8}(g) + 5 O_{2}(g) \longrightarrow 3 CO_{2}(g) + 4 H_{2}O(l) \Delta H_{rxn}^{\circ} = \Delta H_{1} + \Delta H_{2} + \Delta H_{3} \quad [5.29]}$$

(Note that it is sometimes useful to add subscripts to the enthalpy changes, as we have done here, to keep track of the associations between reactions and their ΔH values.)

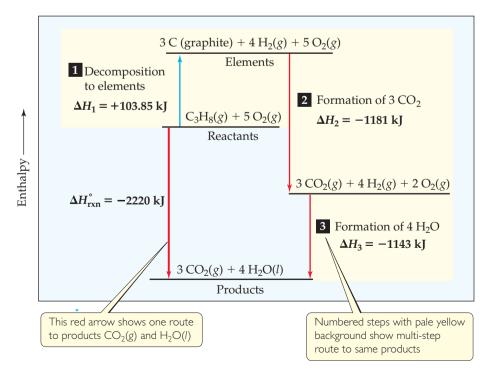

Notice that we have used Hess's law to write the standard enthalpy change for Equation 5.29 as the sum of the enthalpy changes for Equations 5.26 through 5.28. We can use values from Table 5.3 to calculate $\Delta H_{\rm exn}^{\rm c}$:

$$\Delta H_{\text{rxn}}^{\circ} = \Delta H_1 + \Delta H_2 + \Delta H_3$$

$$= -\Delta H_f^{\circ} [C_3 H_8(g)] + 3\Delta H_f^{\circ} [CO_2(g)] + \Delta 4 H_f^{\circ} [H_2O(l)]$$

$$= -(-103.85 \text{ kJ}) + 3(-393.5 \text{ kJ}) + 4(-285.8 \text{ kJ}) = -2220 \text{ kJ}$$
 [5.30]

The enthalpy diagram in ▼ Figure 5.22 shows the components of this calculation. In Step 1 the reactants are decomposed into their constituent elements in their standard states. In Steps 2 and 3 the products are formed from the elements. Several

▲ Figure 5.22 Enthalpy diagram for propane combustion.

aspects of how we use enthalpy changes in this process depend on the guidelines we discussed in Section 5.4.

- **Decomposition.** Equation 5.26 is the reverse of the formation reaction for $C_3H_8(g)$, so the enthalpy change for this decomposition reaction is the negative of the ΔH_f° value for the propane formation reaction: $-\Delta H_f^{\circ} [C_3H_8(g)]$.
- **2** Formation of CO₂. Equation 5.27 is the formation reaction for 3 mol of CO₂(g). Because enthalpy is an extensive property, the enthalpy change for this step is $3\Delta H_f^{\circ}[CO_2(g)]$.
- **3** Formation of H_2O . The enthalpy change for Equation 5.28, formation of 4 mol of H_2O , is $4\Delta H_f^{\circ}[H_2O(l)]$. The reaction specifies that $H_2O(l)$ is produced, so be careful to use the value of ΔH_f° for $H_2O(l)$ and not the value for $H_2O(g)$.

Note that in this analysis we assume that the stoichiometric coefficients in the balanced equation represent the number of moles of each substance. For Equation 5.29, therefore, $\Delta H_{\rm rxn}^{\circ} = -2220\,{\rm kJ}$ represents the enthalpy change for the reaction of 1 mol C_3H_8 and 5 mol O_2 to form 3 mol CO_2 and 4 mol H_2O . The product of the number of moles and the enthalpy change in kJ/mol has the units kJ: (number of moles) \times (ΔH_f° in kJ/mol) = kJ. We therefore report $\Delta H_{\rm rxn}^{\circ}$ in kJ.

We can break down any reaction into formation reactions as we have done here. When we do, we obtain the general result that the standard enthalpy change of a reaction is the sum of the standard enthalpies of formation of the products minus the standard enthalpies of formation of the reactants:

$$\Delta H_{\rm rxn}^{\circ} = \sum n \Delta H_f^{\circ}(\text{products}) - \sum m \Delta H_f^{\circ}(\text{reactants})$$
 [5.31]

The symbol Σ (sigma) means "the sum of," and n and m are the stoichiometric coefficients of the relevant chemical equation. The first term on the right in Equation 5.31 represents the formation reactions of the products, which are written in the "forward" direction in the chemical equation, that is, elements reacting to form products. This term is analogous to Equations 5.27 and 5.28. The second term on the right in Equation 5.31 represents the reverse of the formation reactions of the reactants, analogous to Equation 5.26, which is why this term is preceded by a minus sign.

SAMPLE EXERCISE 5.12 Calculating an Enthalpy of Reaction from Enthalpies of Formation

(a) Calculate the standard enthalpy change for the combustion of 1 mol of benzene, $C_6H_6(l)$, to $CO_2(g)$ and $H_2O(l)$. (b) Compare the quantity of heat produced by combustion of 1.00 g propane with that produced by 1.00 g benzene.

SOLUTION

Analyze (a) We are given a reaction [combustion of $C_6H_6(l)$ to form $CO_2(g)$ and $H_2O(l)$] and asked to calculate its standard enthalpy change, ΔH° . (b) We then need to compare the quantity of

Plan (a) We first write the balanced equation for the combustion of C_6H_6 . We then look up ΔH_f° values in Appendix C or in Table 5.3 and apply Equation 5.31 to calculate the enthalpy change for the reaction. (b) We use the molar mass of C_6H_6 to change the enthalpy

heat produced by combustion of 1.00 g C_6H_6 with that produced by 1.00 g C_3H_8 , whose combustion was treated previously in the text. (See Equations 5.29 and 5.30.)

change per mole to that per gram. We similarly use the molar mass of C_3H_8 and the enthalpy change per mole calculated in the text previously to calculate the enthalpy change per gram of that substance.

Solve

(a) We know that a combustion reaction involves $O_2(g)$ as a reactant. Thus, the balanced equation for the combustion reaction of 1 mol $C_6H_6(l)$ is

We can calculate ΔH° for this reaction by using Equation 5.31 and data in Table 5.3. Remember to multiply the ΔH_f° value for each substance in the reaction by that substance's stoichiometric coefficient. Recall also that $\Delta H_f^{\circ} = 0$ for any element in its most stable form under standard conditions, so $\Delta H_f^{\circ}[O_2(g)] = 0$.

$$C_6H_6(l) + \frac{15}{2}O_2(g) \longrightarrow 6CO_2(g) + 3H_2O(l)$$

$$\begin{split} \Delta H_{\text{rxn}}^{\circ} &= \left[6\Delta H_{f}^{\circ}(\text{CO}_{2}) + 3\Delta H_{f}^{\circ}(\text{H}_{2}\text{O}) \right] - \left[\Delta H_{f}^{\circ}(\text{C}_{6}\text{H}_{6}) + \frac{15}{2}\Delta H_{f}^{\circ}(\text{O}_{2}) \right] \\ &= \left[6(-393.5 \text{ kJ}) + 3(-285.8 \text{ kJ}) \right] - \left[(49.0 \text{ kJ}) + \frac{15}{2}(0 \text{ kJ}) \right] \\ &= (-2361 - 857.4 - 49.0) \text{ kJ} \\ &= -3267 \text{ kJ} \end{split}$$

(b) From the example worked in the text, $\Delta H^{\circ} = -2220 \text{ kJ}$ for the combustion of 1 mol of propane. In part (a) of this exercise we determined that $\Delta H^{\circ} = -3267$ kJ for the combustion of 1 mol benzene. To determine the heat of combustion per gram of each substance, we use the molar masses to convert moles to grams:

 $C_3H_8(g)$: (-2220 kJ/mol)(1 mol/44.1 g) = -50.3 kJ/g $C_6H_6(l)$: (-3267 kJ/mol)(1 mol/78.1 g) = -41.8 kJ/g

Comment Both propane and benzene are hydrocarbons. As a rule, the energy obtained from the combustion of a gram of hydrocarbon is between 40 and 50 kJ.

Practice Exercise 1

Calculate the enthalpy change for the reaction

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$

using enthalpies of formation:

$$\Delta H_f^{\circ}(\mathrm{H_2O_2}) = -187.8 \,\mathrm{kJ/mol}$$
 $\Delta H_f^{\circ}(\mathrm{H_2O_2})$

$$\Delta H_f^{\circ}(\mathrm{H_2O}) = -285.8 \,\mathrm{kJ/mol}$$

(a)
$$-88.0 \, \text{kJ}$$
, (b) $-196.0 \, \text{kJ}$, (c) $+88.0 \, \text{kJ}$, (d) $+196.0 \, \text{kJ}$, (e) more information needed

Practice Exercise 2

Use Table 5.3 to calculate the enthalpy change for the combustion of 1 mol of ethanol:

$$C_2H_5OH(l) + 3 O_2(g) \longrightarrow 2 CO_2(g) + 3 H_2O(l)$$

SAMPLE

EXERCISE 5.13 Calculating an Enthalpy of Formation Using an Enthalpy of Reaction

The standard enthalpy change for the reaction $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$ is 178.1 kJ. Use Table 5.3 to calculate the standard enthalpy of formation of $CaCO_3(s)$.

SOLUTION

Analyze Our goal is to obtain $\Delta H_f^{\circ}(CaCO_3)$.

Plan We begin by writing the expression for the standard enthalpy change for the reaction:

Solve Inserting the given $\Delta H_{\rm rxn}^{\circ}$ and the known $\Delta H_{\rm f}^{\circ}$ values from Table 5.3 or Appendix C, we have

Solving for $\Delta H_f^{\circ}(CaCO_3)$ gives

Check We expect the enthalpy of formation of a stable solid such as calcium carbonate to be negative, as obtained.

$$\Delta H_{\text{rxn}}^{\circ} = \Delta H_{f}^{\circ} \text{CaO} + \Delta H_{f}^{\circ} (\text{CO}_{2}) - \Delta H_{f}^{\circ} \text{1CaCO}_{3}$$

$$178.1\,=\,-635.5\,kJ\,-\,393.5\,kJ\,-\,\Delta H_{\!f}^{\,\circ}(\text{CaCO}_3)$$

$$\Delta H_f^{\circ}(CaCO_3) = -1207.1 \text{ kJ/mol}$$

Practice Exercise 1

Given $2 SO_2(g) + O_2(g) \longrightarrow 2 SO_3(g)$, which of the following equations is correct?

(a)
$$\Delta H_f^{\circ}(SO_3) = \Delta H_{rxn}^{\circ} - \Delta H_f^{\circ}(SO_2)$$

(b)
$$\Delta H_f^{\circ}(SO_3) = \Delta H_{rxn}^{\circ} + \Delta H_f^{\circ}(SO_2)$$

(c)
$$2\Delta H_f^{\circ}(SO_3) = \Delta H_{rxn}^{\circ} + 2\Delta H_f^{\circ}(SO_2)$$

(d)
$$2\Delta H_f^{\circ}(SO_3) = \Delta H_{rxn}^{\circ} - 2\Delta H_f^{\circ}(SO_2)$$

(e)
$$2\Delta H_f^{\circ}(SO_3) = 2\Delta H_f^{\circ}(SO_2) - \Delta H_{rxn}^{\circ}$$

Practice Exercise 2

Given the following standard enthalpy change, use the standard enthalpies of formation in Table 5.3 to calculate the standard enthalpy of formation of CuO(s):

$$CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(l) \qquad \Delta H^{\circ} = -129.7 \text{ kJ}$$

5.8 Foods and Fuels

Most chemical reactions used for the production of heat are combustion reactions. The energy released when one gram of any substance is combusted is the fuel value of the substance. The fuel value of any food or fuel can be measured by calorimetry.

Foods

Most of the energy our bodies need comes from carbohydrates and fats. The carbohydrates known as starches are decomposed in the intestines into glucose, C₆H₁₂O₆. Glucose is soluble in blood, and in the human body it is known as blood sugar. It is transported by the blood to cells where it reacts with O_2 in a series of steps, eventually producing $CO_2(g)$, $H_2O(l)$, and energy:

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(l)$$
 $\Delta H^{\circ} = -2803 \text{ kJ}$

Because carbohydrates break down rapidly, their energy is quickly supplied to the body. However, the body stores only a very small amount of carbohydrates. The average fuel value of carbohydrates is $17 \, kJ/g \, (4 \, kcal/g)$.*

Like carbohydrates, fats produce CO_2 and H_2O when metabolized. The reaction of tristearin, $C_{57}H_{110}O_6$, a typical fat, is

$$2 C_{57} H_{110} O_6(s) + 163 O_2(g) \longrightarrow 114 CO_2(g) + 110 H_2 O(l)$$
 $\Delta H^{\circ} = 275,520 \text{ kJ}$

The body uses the chemical energy from foods to maintain body temperature (see the "Chemistry and Life" box in Section 5.5), to contract muscles, and to construct and repair tissues. Any excess energy is stored as fats. Fats are well suited to serve as the body's energy reserve for at least two reasons: (1) They are insoluble in water, which facilitates storage in the body, and (2) they produce more energy per gram than either proteins or carbohydrates, which makes them efficient energy sources on a mass basis. The average fuel value of fats is $38 \, \text{kJ/g}$ (9 kcal/g).

The combustion of carbohydrates and fats in a bomb calorimeter gives the same products as when they are metabolized in the body. The metabolism of proteins produces less energy than combustion in a calorimeter because the products are different. Proteins contain nitrogen, which is released in the bomb calorimeter as N_2 . In the body this nitrogen ends up mainly as urea, $(NH_2)_2CO$. Proteins are used by the body mainly as building materials for organ walls, skin, hair, muscle, and so forth. On average, the metabolism of proteins produces 17 kJ/g (4 kcal/g), the same as for carbohydrates.

Fuel values for some common foods are shown in ▼ Table 5.4. Labels on packaged foods show the amounts of carbohydrate, fat, and protein contained in an average serving, as well as the amount of energy supplied by a serving (▶ Figure 5.23).

The amount of energy our bodies require varies considerably, depending on such factors as weight, age, and muscular activity. About 100 kJ per kilogram of body mass per day is required to keep the body functioning at a minimal level. An average 70-kg

GO FIGURE

Which value would change most if this label were for skim milk instead of whole milk: grams of fat, grams of total carbohydrate, or grams of protein?

Vitamin D Mill

▲ Figure 5.23 Nutrition label for whole milk.

Table 5.4 Compositions and Fuel Values of Some Common Foods

	Approximate Composition (% by Mass)		by Mass)	Fuel Value	
	Carbohydrate	Fat	Protein	kJ/g	kcal/g (Cal/g)
Carbohydrate	100	_	_	17	4
Fat	_	100	_	38	9
Protein	_	_	100	17	4
Apples	13	0.5	0.4	2.5	0.59
Beer ^a	1.2	_	0.3	1.8	0.42
Bread	52	3	9	12	2.8
Cheese	4	37	28	20	4.7
Eggs	0.7	10	13	6.0	1.4
Fudge	81	11	2	18	4.4
Green beans	7.0	_	1.9	1.5	0.38
Hamburger	_	30	22	15	3.6
Milk (whole)	5.0	4.0	3.3	3.0	0.74
Peanuts	22	39	26	23	5.5

^aBeer typically contains 3.5% ethanol, which has fuel value.

^{*}Although fuel values represent the heat *released* in a combustion reaction, fuel values are reported as positive numbers

(154-lb) person expends about 800 kJ/h when doing light work, and strenuous activity often requires 2000 kJ/h or more. When the fuel value, or caloric content, of the food we ingest exceeds the energy we expend, our body stores the surplus as fat.

Give It Some Thought

Which releases the greatest amount of energy per gram when metabolized? Carbohydrates, proteins, or fats.

SAMPLE

EXERCISE 5.14 Estimating the Fuel Value of a Food from Its Composition

(a) A 28-g (1-oz) serving of a popular breakfast cereal served with 120 mL of skim milk provides 8 g protein, 26 g carbohydrates, and 2 g fat. Using the average fuel values of these substances, estimate the fuel value (caloric content) of this serving. (b) A person of average weight uses about 100 Cal/mi when running or jogging. How many servings of this cereal provide the fuel value requirements to run 3 mi?

SOLUTION

Analyze The fuel value of the serving will be the sum of the fuel values of the protein, carbohydrates, and fat.

Plan We are given the masses of the protein, carbohydrates, and fat contained in a serving. We can use the data in Table 5.4 to convert these masses to their fuel values, which we can sum to get the total fuel value.

$$(8 \text{ g.protein}) \left(\frac{17 \text{ kJ}}{1 \text{ g.protein}}\right) + (26 \text{ g.carbohydrate}) \left(\frac{17 \text{ kJ}}{1 \text{ g.carbohydrate}}\right) + \\ (2 \text{ g.fat}) \left(\frac{38 \text{ kJ}}{1 \text{ g.fat}}\right) = 650 \text{ kJ (to two significant figures)}$$

This corresponds to 160 kcal:

$$(650 \,\mathrm{kJ}) \left(\frac{1 \,\mathrm{kcal}}{4.18 \,\mathrm{kJ}} \right) = 160 \,\mathrm{kcal}$$

Recall that the dietary Calorie is equivalent to 1 kcal. Thus, the serving provides 160 Cal.

Analyze Here we are faced with the reverse problem, calculating the quantity of food that provides a specific fuel value.

Plan The problem statement provides a conversion factor between Calories and miles. The answer to part (a) provides us with a conversion factor between servings and Calories.

Solve We can use these factors in a straightforward dimensional analysis to determine the number of servings needed, rounded to the nearest whole number:

Servings =
$$(3 \text{ mi}) \left(\frac{100 \text{ Cal}}{1 \text{ mi}} \right) \left(\frac{1 \text{ serving}}{160 \text{ Cal}} \right) = 2 \text{ servings}$$

Practice Exercise 1

A stalk of celery has a caloric content (fuel value) of 9.0 kcal. If 1.0 kcal is provided by fat and there is very little protein, estimate the number of grams of carbohydrate and fat in the celery. (a) 2 g carbohydrate and 0.1 g fat, (b) 2 g carbohydrate and 1 g fat, (c) 1 g carbohydrate and 2 g fat, (d) 2.2 g carbohydrate and 0.1 g fat, (e) 32 g carbohydrate and 10 g fat.

Practice Exercise 2

(a) Dry red beans contain 62% carbohydrate, 22% protein, and 1.5% fat. Estimate the fuel value of these beans. (b) During a very light activity, such as reading or watching television, the average adult expends about 7 kJ/min. How many minutes of such activity can be sustained by the energy provided by a serving of chicken noodle soup containing 13 g protein, 15 g carbohydrate, and 5 g fat?

Fuels

During the complete combustion of fuels, carbon is converted to CO_2 and hydrogen is converted to H_2O , both of which have large negative enthalpies of formation. Consequently, the greater the percentage of carbon and hydrogen in a fuel, the higher its fuel value. In \blacktriangledown Table 5.5, for example, compare the compositions and fuel values of bituminous coal and wood. The coal has a higher fuel value because of its greater carbon content.

In 2011 the United States consumed 1.03×10^{17} kJ of energy. This value corresponds to an average daily energy consumption per person of 9.3×10^5 kJ roughly 100 times greater than the per capita food-energy needs. Figure 5.24 illustrates the sources of this energy.

Coal, petroleum, and natural gas, which are the world's major sources of energy, are known as **fossil fuels**. All have formed over millions of years from the decomposition of plants and animals and are being depleted far more rapidly than they are being formed.

Natural gas consists of gaseous hydrocarbons, compounds of hydrogen and carbon. It contains primarily methane (CH_4) , with small amounts of ethane (C_2H_6) , propane (C_3H_8) , and butane (C_4H_{10}) . We determined the fuel value of propane in Sample Exercise 5.11. Natural gas burns with far fewer byproducts and produces less CO_2 than either petroleum or coal. **Petroleum** is a liquid composed of hundreds of compounds, most of which are hydrocarbons, with the remainder being chiefly organic compounds containing sulfur, nitrogen, or oxygen. **Coal**, which is solid, contains hydrocarbons of high molecular weight as well as compounds containing sulfur, oxygen, or nitrogen. Coal is the most abundant fossil fuel; current reserves are projected to last for well over 100 years at current consumption rates. However, the use of coal presents a number of problems.

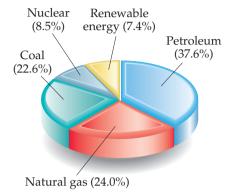

Coal is a complex mixture of substances, and it contains components that cause air pollution. When coal is combusted, the sulfur it contains is converted mainly to sulfur dioxide, SO₂, a troublesome air pollutant. Because coal is a solid, recovery from its underground deposits is expensive and often dangerous. Furthermore, coal deposits are not always close to locations of high-energy use, so there are often substantial shipping costs.

Fossil fuels release energy in combustion reactions, which ideally produce only CO_2 and H_2O . The production of CO_2 has become a major issue that involves science and public policy because of concerns that increasing concentrations of atmospheric CO_2 are causing global climate changes. We will discuss the environmental aspects of atmospheric CO_2 in Chapter 18.

Table 5.5 Fuel Values and Compositions of Some Common Fuels

		oximate Ele osition (Ma		
	C	Н	0	Fuel Value (kJ/g)
Wood (pine)	50	6	44	18
Anthracite coal (Pennsylvania)	82	1	2	31
Bituminous coal (Pennsylvania)	77	5	7	32
Charcoal	100	0	0	34
Crude oil (Texas)	85	12	0	45
Gasoline	85	15	0	48
Natural gas	70	23	0	49
Hydrogen	0	100	0	142

▲ Figure 5.24 Energy consumption in the United States.* In 2011 the United States consumed a total of 1.03×10^{17} kJ of energy.

Other Energy Sources

Nuclear energy is the energy released in either the fission (splitting) or the fusion (combining) of atomic nuclei. Nuclear power based on nuclear fission is currently used to produce about 21% of the electric power in the United States and makes up about 8.5% of the total U.S. energy production (Figure 5.24). Nuclear energy is, in principle, free of the polluting emissions that are a major problem with fossil fuels. However, nuclear power plants produce radioactive waste products, and their use has therefore been controversial. We will discuss issues related to the production of nuclear energy in Chapter 21.

Fossil fuels and nuclear energy are *nonrenewable* sources of energy—they are limited resources that we are consuming at a much greater rate than they can be regenerated. Eventually these fuels will be expended, although estimates vary greatly as to when this will occur. Because nonrenewable energy sources will eventually be used up, a great deal of research is being conducted on **renewable energy sources**, sources that are essentially inexhaustible. Renewable energy sources include *solar energy* from the Sun, *wind energy* harnessed by windmills, *geothermal energy* from the heat stored inside Earth, *hydroelectric energy* from flowing rivers, and *biomass energy* from crops and biological waste matter. Currently, renewable sources provide about 7.4% of the U.S. annual energy consumption, with hydroelectric and biomass sources the major contributors.

Fulfilling our future energy needs will depend on developing technology to harness solar energy with greater efficiency. Solar energy is the world's largest energy source. On a clear day about 1 kJ of solar energy reaches each square meter of Earth's surface every second. The average solar energy falling on only 0.1% of U.S. land area is equivalent to all the energy this nation currently uses. Harnessing this energy is difficult because it is dilute (that is, distributed over a wide area) and varies with time of day and weather conditions. The effective use of solar energy will depend on the development of some means of storing and distributing it. Any practical means for doing this will almost certainly involve an endothermic chemical process that can be later reversed to release heat. One such reaction is

$$CH_4(g) + H_2O(g) + heat \longrightarrow CO(g) + 3H_2(g)$$

This reaction proceeds in the forward direction at high temperatures, which can be obtained in a solar furnace. The CO and H_2 formed in the reaction could then be stored and allowed to react later, with the heat released being put to useful work.

Chemistry Put to Work

The Scientific and Political Challenges of Biofuels*

One of the biggest challenges facing us in the twenty-first century is production of abundant sources of energy, both food and fuels. At the end of 2012, the global population was about 7.0 billion people, and it is growing at a rate of about 750 million per decade. A growing world population puts greater demands on the global food supply, especially in Asia and Africa, which together make up more than 75% of the world population.

A growing population also increases demands on the production of fuels for transportation, industry, electricity, heating, and cooling. As populous countries such as China and India have modernized, their per capita consumption of energy has increased significantly. In China, for instance, per capita energy consumption roughly doubled between 1990 and 2010, and in 2010 China passed the United States as the world's largest user of energy (although it is still less than 20% of U.S. per capita energy consumption).

Global fuel energy consumption in 2012 was more than 5×10^{17} kJ, a staggeringly large number. More than 80% of current energy requirements comes from combustion of nonrenewable fossil fuels, especially

coal and petroleum. The exploration of new fossil-fuel sources often involves environmentally sensitive regions, making the search for new supplies of fossil fuels a major political and economic issue.

The global importance of petroleum is in large part because it provides liquid fuels, such as gasoline, that are critical to supplying transportation needs. One of the most promising—but controversial—alternatives to petroleum-based fuels is *biofuels*, liquid fuels derived from biological matter. The most common approach to producing biofuels is to transform plant sugars and other carbohydrates into combustible liquids.

The most commonly produced biofuel is *bioethanol*, which is ethanol (C_2H_5OH) made from fermentation of plant carbohydrates. The fuel value of ethanol is about two-thirds that of gasoline and is therefore comparable to that of coal (Table 5.5). The United States and Brazil dominate bioethanol production, together supplying 85% of the world's total.

In the United States, nearly all the bioethanol currently produced is made from yellow feed corn. Glucose $(C_6H_{12}O_6)$ in the corn is converted to ethanol and CO_2 :

$$C_6H_{12}O_6(s) \longrightarrow 2 C_2H_5OH(l) + 2 CO_2(g)$$
 $\Delta H = 15.8 KJ$

^{*}Data from the Annual Energy Outlook 2012, U.S. Energy Information Administration.

Notice that this reaction is anaerobic—it does not involve $O_2(g)$ —and that the enthalpy change is positive and much smaller in magnitude than for most combustion reactions. Other carbohydrates can be converted to ethanol in similar fashion.

Producing bioethanol from corn is controversial for two main reasons. First, growing and transporting corn are both energy-intensive processes, and growing it requires the use of fertilizers. It is estimated that the *energy return* on corn-based bioethanol is only 34%—that is, for each 1.00 J of energy expended to produce the corn, 1.34 J of energy is produced in the form of bioethanol. Second, the use of corn as a starting material for making bioethanol competes with its use as an important component of the food chain (the so-called food versus fuel debate).

Much current research focuses on the formation of bioethanol from *cellulosic* plants, plants that contain the complex carbohydrate cellulose. Cellulose is not readily metabolized and so does not compete with the food supply. However, the chemistry for converting cellulose to ethanol is much more complex than that for converting corn. Cellulosic bioethanol could be produced from very fast-growing nonfood plants, such as prairie grasses and switchgrass, which readily renew themselves without the use of fertilizers.

The Brazilian bioethanol industry uses sugarcane as its feedstock (**Figure 5.25**). Sugarcane grows much faster than corn and without the need for fertilizers or tending. Because of these differences, the energy return for sugarcane is much higher than the energy return for corn. It is estimated that for each 1.0 J of energy expended in growing and processing sugarcane, 8.0 J of energy is produced as bioethanol.

▲ Figure 5.25 Sugarcane can be converted to a sustainable bioethanol product.

Other biofuels that are also becoming a major part of the world economy include *biodiesel*, a substitute for petroleum-derived diesel fuel. Biodiesel is typically produced from crops that have a high oil content, such as soybeans and canola. It can also be produced from animal fats and waste vegetable oil from the food and restaurant industry.

Related Exercises: 5.89, 5.90, 5.111, 5.119

Plants utilize solar energy in *photosynthesis*, the reaction in which the energy of sunlight is used to convert CO_2 and H_2O into carbohydrates and O_2 :

$$6 \text{ CO}_2(g) + 6 \text{ H}_2\text{O}(l) + \text{sunlight} \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(s) + 6 \text{ O}_2(g)$$
 [5.32]

Photosynthesis is an important part of Earth's ecosystem because it replenishes atmospheric O_2 , produces an energy-rich molecule that can be used as fuel, and consumes some atmospheric O_2 .

Perhaps the most direct way to use the Sun's energy is to convert it directly into electricity in photovoltaic devices, or *solar cells*, which we mentioned at the beginning of this chapter. The efficiencies of such devices have increased dramatically during the past few years. Technological advances have led to solar panels that last longer and produce electricity with greater efficiency at steadily decreasing unit cost. Indeed, the future of solar energy is, like the Sun itself, very bright.

SAMPLE INTEGRATIVE EXERCISE

Putting Concepts Together

Trinitroglycerin, $C_3H_5N_3O_9$ (usually referred to simply as nitroglycerin), has been widely used as an explosive. Alfred Nobel used it to make dynamite in 1866. Rather surprisingly, it also is used as a medication, to relieve angina (chest pains resulting from partially blocked arteries to the heart) by dilating the blood vessels. At 1 atm pressure and 25 °C, the enthalpy of decomposition of trinitroglycerin to form nitrogen gas, carbon dioxide gas, liquid water, and oxygen gas is $-1541.4 \, kJ/mol$.

- (a) Write a balanced chemical equation for the decomposition of trinitroglycerin.
- (b) Calculate the standard heat of formation of trinitroglycerin.
- (c) A standard dose of trinitroglycerin for relief of angina is 0.60 mg. If the sample is eventually oxidized in the body (not explosively, though!) to nitrogen gas, carbon dioxide gas, and liquid water, what number of calories is released?
- (d) One common form of trinitroglycerin melts at about 3 °C. From this information and the formula for the substance, would you expect it to be a molecular or ionic compound? Explain.
- (e) Describe the various conversions of forms of energy when trinitroglycerin is used as an explosive to break rockfaces in highway construction.

SOLUTION

(a) The general form of the equation we must balance is

$$C_3H_5N_3O_9(l) \longrightarrow N_2(g) + CO_2(g) + H_2O(l) + O_2(g)$$

We go about balancing in the usual way. To obtain an even number of nitrogen atoms on the left, we multiply the formula for $C_3H_5N_3O_9$ by 2, which gives us 3 mol of N_2 , 6 mol of CO_2 and 5 mol of H_2O . Everything is then balanced except for oxygen. We have an odd number of oxygen atoms on the right. We can balance the oxygen by using the coefficient $\frac{1}{2}$ for O_2 on the right:

$$2 C_3 H_5 N_3 O_9(l) \longrightarrow 3 N_2(g) + 6 CO_2(g) + 5 H_2 O(l) + \frac{1}{2} O_2(g)$$

We multiply through by 2 to convert all coefficients to whole numbers:

$$4 C_3 H_5 N_3 O_9(l) \longrightarrow 6 N_2(g) + 12 CO_2(g) + 10 H_2 O(l) + O_2(g)$$

(At the temperature of the explosion, water is a gas. The rapid expansion of the gaseous products creates the force of an explosion.)

(b) We can obtain the standard enthalpy of formation of nitroglycerin by using the heat of decomposition of trinitroglycerin together with the standard enthalpies of formation of the other substances in the decomposition equation:

$$4 C_3 H_5 N_3 O_9(l) \longrightarrow 6 N_2(g) + 12 CO_2(g) + 10 H_2 O(l) + O_2(g)$$

The enthalpy change for this decomposition is $4(-1541.4 \, kJ) = -6165.6 \, kJ$. [We need to multiply by 4 because there are 4 mol of $C_3H_5N_3O_9(l)$ in the balanced equation.]

This enthalpy change equals the sum of the heats of formation of the products minus the heats of formation of the reactants, each multiplied by its coefficient in the balanced equation:

$$-6165.6 \text{ kJ} = 6\Delta H_f^{\circ}[N_2(g)] + 12\Delta H_f^{\circ}[CO_2(g)] + 10\Delta H_f^{\circ}[H_2O(l)] + \Delta H_f^{\circ}[O_2(g)]$$

$$-4\Delta H_f^{\circ}[C_3H_5N_3O_9(l)]$$

The ΔH_j^c values for $N_2(g)$ and $O_2(g)$ are zero, by definition. Using the values for $H_2O(l)$ and $CO_2(g)$ from Table 5.3 or Appendix C, we have

$$-6165.6 \text{ kJ} = 12(-393.5 \text{ kJ}) + 10(-285.8 \text{ kJ}) - 4\Delta H_f^{\circ}[C_3H_5N_3O_9(l)]$$

$$\Delta H_f^{\circ}[C_3H_5N_3O_9(l)] = -353.6 \text{ kJ/mol}$$

(c) Converting 0.60 mg $C_3H_5N_3O_9(l)$ to moles and using the fact that the decomposition of 1 mol of $C_3H_5N_3O_9(l)$ yields 1541.4 kJ we have:

$$(0.60 \times 10^{-3} \text{ g C}_3\text{H}_5\text{N}_3\text{O}_9) \left(\frac{1 \text{ mol C}_3\text{H}_5\text{N}_3\text{O}_9}{227 \text{ g C}_3\text{H}_5\text{N}_3\text{O}_9}\right) \left(\frac{1541.4 \text{ kJ}}{1 \text{ mol C}_3\text{H}_5\text{N}_3\text{O}_9}\right) = 4.1 \times 10^{-3} \text{ kJ}$$

$$= 4.1 \text{ J}$$

- (d) Because trinitroglycerin melts below room temperature, we expect that it is a molecular compound. With few exceptions, ionic substances are generally hard, crystalline materials that melt at high temperatures. (Sections 2.6 and 2.7) Also, the molecular formula suggests that it is a molecular substance because all of its constituent elements are nonmetals.
- (e) The energy stored in trinitroglycerin is chemical potential energy. When the substance reacts explosively, it forms carbon dioxide, water, and nitrogen gas, which are of lower potential energy. In the course of the chemical transformation, energy is released in the form of heat; the gaseous reaction products are very hot. This high heat energy is transferred to the surroundings. Work is done as the gases expand against the surroundings, moving the solid materials and imparting kinetic energy to them. For example, a chunk of rock might be impelled upward. It has been given kinetic energy by transfer of energy from the hot, expanding gases. As the rock rises, its kinetic energy is transformed into potential energy. Eventually, it again acquires kinetic energy as it falls to Earth. When it strikes Earth, its kinetic energy is converted largely to thermal energy, though some work may be done on the surroundings as well.

Chapter Summary and Key Terms

ENERGY (INTRODUCTION AND SECTION 5.1) Thermodynamics is the study of energy and its transformations. In this chapter we have focused on **thermochemistry**, the transformations of energy—especially heat—during chemical reactions.

An object can possess energy in two forms: (1) kinetic energy, which is the energy due to the motion of the object, and (2) potential energy,

which is the energy that an object possesses by virtue of its position relative to other objects. An electron in motion near a proton has kinetic energy because of its motion and potential energy because of its electrostatic attraction to the proton.

The SI unit of energy is the joule (J): $1 \text{ J} = 1 \text{ kg-m}^2/\text{s}^2$. Another common energy unit is the calorie (cal), which was originally defined

as the quantity of energy necessary to increase the temperature of 1 g of water by 1 $^{\circ}$ C: 1 cal = 4.184 J.

When we study thermodynamic properties, we define a specific amount of matter as the **system**. Everything outside the system is the **surroundings**. When we study a chemical reaction, the system is generally the reactants and products. A closed system can exchange energy, but not matter, with the surroundings.

Energy can be transferred between the system and the surroundings as work or heat. **Work** is the energy expended to move an object against a **force**. **Heat** is the energy that is transferred from a hotter object to a colder one. **Energy** is the capacity to do work or to transfer heat.

THE FIRST LAW OF THERMODYNAMICS (SECTION 5.2) The **internal energy** of a system is the sum of all the kinetic and potential energies of its component parts. The internal energy of a system can change because of energy transferred between the system and the surroundings.

According to the **first law of thermodynamics**, the change in the internal energy of a system, ΔE , is the sum of the heat, q, transferred into or out of the system and the work, w, done on or by the system: $\Delta E = q + w$. Both q and w have a sign that indicates the direction of energy transfer. When heat is transferred from the surroundings to the system, q > 0. Likewise, when the surroundings do work on the system, w > 0. In an **endothermic** process the system absorbs heat from the surroundings; in an **exothermic** process the system releases heat to the surroundings.

The internal energy, *E*, is a **state function**. The value of any state function depends only on the state or condition of the system and not on the details of how it came to be in that state. The heat, *q*, and the work, *w*, are not state functions; their values depend on the particular way by which a system changes its state.

ENTHALPY (SECTIONS 5.3 AND 5.4) When a gas is produced or consumed in a chemical reaction occurring at constant pressure, the system may perform **pressure-volume** (P-V) work against the prevailing pressure of the surroundings. For this reason, we define a new state function called **enthalpy**, H, which is related to energy: H = E + PV. In systems where only pressure-volume work is involved, the change in the enthalpy of a system, ΔH , equals the heat gained or lost by the system at constant pressure: $\Delta H = q_p$ (the subscript P denotes constant pressure). For an endothermic process, $\Delta H > 0$; for an exothermic process, $\Delta H < 0$.

In a chemical process, the **enthalpy of reaction** is the enthalpy of the products minus the enthalpy of the reactants: $\Delta H_{\rm rxn} = H({\rm products}) - H({\rm reactants})$. Enthalpies of reaction follow some simple rules: (1) The enthalpy of reaction is proportional to the amount of reactant that reacts. (2) Reversing a reaction changes the sign of ΔH . (3) The enthalpy of reaction depends on the physical states of the reactants and products.

CALORIMETRY (SECTION 5.5) The amount of heat transferred between the system and the surroundings is measured experimentally by **calorimetry**. A **calorimeter** measures the temperature change accompanying a process. The temperature change of a calorimeter depends on its **heat capacity**, the amount of heat required to raise its temperature by 1 K. The heat capacity for one mole of a pure substance is called its **molar heat capacity**; for one gram of the substance, we use the term **specific heat**. Water has a very high specific heat, 4.18 J/g-K. The amount of heat, q, absorbed by a substance is the product of its specific heat (C_s) , its mass, and its temperature change: $q = C_s \times m \times \Delta T$.

If a calorimetry experiment is carried out under a constant pressure, the heat transferred provides a direct measure of the enthalpy change of the reaction. Constant-volume calorimetry is carried out in a vessel of fixed volume called a **bomb calorimeter**. The heat transferred under constant-volume conditions is equal to ΔE . Corrections can be applied to ΔE values to yield ΔH .

HESS'S LAW (SECTION 5.6) Because enthalpy is a state function, ΔH depends only on the initial and final states of the system. Thus, the enthalpy change of a process is the same whether the process is carried out in one step or in a series of steps. **Hess's law** states that if a reaction is carried out in a series of steps, ΔH for the reaction will be equal to the sum of the enthalpy changes for the steps. We can therefore calculate ΔH for any process, as long as we can write the process as a series of steps for which ΔH is known.

ENTHALPIES OF FORMATION (SECTION 5.7) The **enthalpy of formation**, $\Delta H_{f^{\circ}}$ of a substance is the enthalpy change for the reaction in which the substance is formed from its constituent elements. Usually enthalpies are tabulated for reactions where reactants and products are in their **standard states**. The standard state of a substance is its pure, most stable form at 1 atm and the temperature of interest (usually 298 K). Thus, the **standard enthalpy change** of a reaction, ΔH° , is the enthalpy change when all reactants and products are in their standard states. The **standard enthalpy of formation**, $\Delta H_{f^{\circ}}$, of a substance is the change in enthalpy for the reaction that forms one mole of the substance from its elements in their standard states. For any element in its standard state, $\Delta H_{f^{\circ}} = 0$.

The standard enthalpy change for any reaction can be readily calculated from the standard enthalpies of formation of the reactants and products in the reaction:

$$\Delta H_{\rm rxn}^{\circ} = \Sigma n \Delta H_{\rm f}^{\circ}({\rm products}) - \Sigma m \Delta H_{\rm f}^{\circ}({\rm reactants})$$

FOODS AND FUELS (SECTION 5.8) The fuel value of a substance is the heat released when one gram of the substance is combusted. Different types of foods have different fuel values and differing abilities to be stored in the body. The most common fuels are hydrocarbons that are found as fossil fuels, such as natural gas, petroleum, and coal. Renewable energy sources include solar energy, wind energy, biomass, and hydroelectric energy. Nuclear power does not utilize fossil fuels but does create controversial waste-disposal problems.

Learning Outcomes After studying this chapter, you should be able to:

- Interconvert energy units. (Section 5.1)
- Distinguish between the system and the surroundings in thermodynamics. (Section 5.1)
- Calculate internal energy from heat and work and state the sign conventions of these quantities. (Section 5.2)
- Explain the concept of a state function and give examples. (Section 5.2)
- Calculate ΔH from ΔE and $P\Delta V$ (Section 5.3)
- Relate q_p to ΔH and indicate how the signs of q and ΔH relate to whether a process is exothermic or endothermic. (Sections 5.2 and 5.3)
- Use thermochemical equations to relate the amount of heat energy transferred in reactions at constant pressure (ΔH) to the amount of substance involved in the reaction. (Section 5.4)

- Calculate the heat transferred in a process from temperature measurements together with heat capacities or specific heats (calorimetry). (Section 5.5)
- Use Hess's law to determine enthalpy changes for reactions. (Section 5.6)
- Use standard enthalpies of formation to calculate ΔH° for reactions. (Section 5.7)

Key Equations

• $E_k = \frac{1}{2}mv^2$	[5.1]	Kinetic energy
• $w = F \times d$	[5.3]	Relates work to force and distance
• $\Delta E = E_{\text{final}} - E_{\text{initial}}$	[5.4]	The change in internal energy
• $\Delta E = q + w$	[5.5]	Relates the change in internal energy to heat and work (the first law of thermodynamics)
• $H = E + PV$	[5.6]	Defines enthalpy
• $w = -P \Delta V$	[5.8]	The work done by an expanding gas at constant pressure
$\bullet \Delta H = \Delta E + P \Delta V = q_P$	[5.10]	Enthalpy change at constant pressure
• $q = C_{\rm s} \times m \times \Delta T$	[5.22]	Heat gained or lost based on specific heat, mass, and temperature change
• $q_{\rm rxn} = -C_{\rm cal} \times \Delta T$	[5.24]	Heat exchanged between a reaction and calorimeter
• $\Delta H_{\rm rxn}^{\circ} = \Sigma n \Delta H_f^{\circ}({\rm products}) - \Sigma m \Delta H_f^{\circ}({\rm reactants})$	[5.31]	Standard enthalpy change of a reaction

Exercises

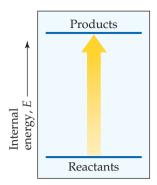

Visualizing Concepts

- 5.1 Imagine a book that is falling from a shelf. At a particular moment during its fall, the book has a kinetic energy of 24 J and a potential energy with respect to the floor of 47 J. (a) How do the book's kinetic energy and its potential energy change as it continues to fall? (b) What was the initial potential energy of the book, and what is its total kinetic energy at the instant just before it strikes the floor? (c) If a heavier book fell from the same shelf, would it have the same kinetic energy when it strikes the floor? [Section 5.1]
- **5.2** The accompanying photo shows a pipevine swallowtail caterpillar climbing up a twig. (a) As the caterpillar climbs, its potential energy is increasing. What source of energy has been used to effect this change in potential energy? (b) If the caterpillar is the system, can you predict the sign of *q* as the caterpillar climbs? (c) Does the caterpillar do work in climbing the twig? Explain. (d) Does the amount of work done in climbing a 12-inch section of the twig depend on the speed of the caterpillar's climb? (e) Does the change

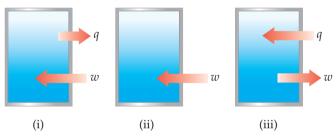

in potential energy depend on the caterpillar's speed of climb? [Section 5.1]

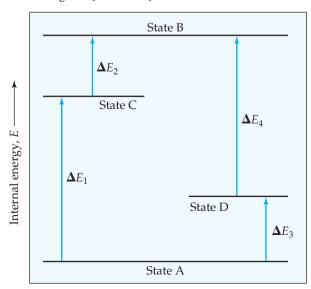

5.3 Consider the accompanying energy diagram. (a) Does this diagram represent an increase or decrease in the internal energy of the system? (b) What sign is given to ΔE for this process? (c) If there is no work associated with the process, is it exothermic or endothermic? [Section 5.2]

5.4 The contents of the closed box in each of the following illustrations represent a system, and the arrows show the changes to the system during some process. The lengths of the arrows represent the relative magnitudes of q and w. (a) Which of these processes is endothermic? (b) For which of these processes, if any, is $\Delta E < 0$? (c) For which process, if any, does the system experience a net gain in internal energy? [Section 5.2]

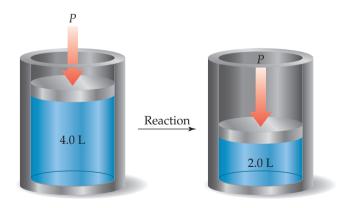

- 5.5 Imagine that you are climbing a mountain. (a) Is the distance you travel to the top a state function? Why or why not? (b) Is the change in elevation between your base camp and the peak a state function? Why or why not? [Section 5.2]
- 5.6 The diagram shows four states of a system, each with different internal energy, E. (a) Which of the states of the system has the greatest internal energy? (b) In terms of the ΔE values, write two expressions for the difference in internal energy between State A and State B. (c) Write an expression for the difference in energy between State C and State D. (d) Suppose there is another state of the system, State E, and its energy relative to State A is $\Delta E = \Delta E_1 + \Delta E_4$. Where would State E be on the diagram? [Section 5.2]

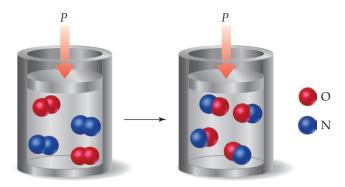

- 5.7 You may have noticed that when you compress the air in a bicycle pump, the body of the pump gets warmer. (a) Assuming the pump and the air in it comprise the system, what is the sign of w when you compress the air? (b) What is the sign of q for this process? (c) Based on your answers to parts (a) and (b), can you determine the sign of ΔE for compressing the air in the pump? If not, what would you expect for the sign of ΔE ? What is your reasoning? [Section 5.2]
- 5.8 Imagine a container placed in a tub of water, as depicted in the accompanying diagram. (a) If the contents of the container are the system and heat is able to flow through the container walls, what qualitative changes will occur in the temperatures of the system and in its surroundings? What is the sign of *q* associated with each change? From the system's perspective, is the process exothermic or endothermic? (b) If neither the volume nor the pressure of the system changes during the process, how is the change in internal energy related to the change in enthalpy? [Sections 5.2 and 5.3]

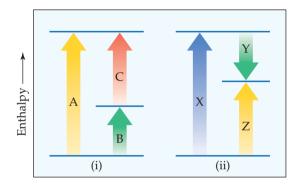

5.9 In the accompanying cylinder diagram a chemical process occurs at constant temperature and pressure. (a) Is the sign of w indicated by this change positive or negative? (b) If the process is endothermic, does the internal energy of the system within the cylinder increase or decrease during the change and is ΔE positive or negative? [Sections 5.2 and 5.3]

5.10 The gas-phase reaction shown, between N₂ and O₂, was run in an apparatus designed to maintain a constant pressure.
(a) Write a balanced chemical equation for the reaction depicted and predict whether w is positive, negative, or zero.
(b) Using data from Appendix C, determine ΔH for the formation of one mole of the product. Why is this enthalpy change called the enthalpy of formation of the involved product? [Sections 5.3 and 5.7]

5.11 Consider the two diagrams that follow. (a) Based on (i), write an equation showing how $\Delta H_{\rm A}$ is related to $\Delta H_{\rm B}$ and $\Delta H_{\rm C}$. How do both diagram (i) and your equation relate to the fact that enthalpy is a state function? (b) Based on (ii), write an equation relating $\Delta H_{\rm Z}$ to the other enthalpy changes in the diagram. (c) How do these diagrams relate to Hess's law? [Section 5.6]

5.12 Consider the conversion of compound A into compound B: A \longrightarrow B. For both compounds A and B, $\Delta H_f^{\circ} > 0$. (a) Sketch an enthalpy diagram for the reaction that is analogous to Figure 5.22. (b) Suppose the overall reaction is exothermic. What can you conclude? [Section 5.7]

The Nature of Energy (Section 5.1)

- **5.13** In what two ways can an object possess energy? How do these two ways differ from one another?
- 5.14 Suppose you toss a tennis ball upward. (a) Does the kinetic energy of the ball increase or decrease as it moves higher? (b) What happens to the potential energy of the ball as it moves higher? (c) If the same amount of energy were imparted to a ball the same size as a tennis ball but of twice the mass, how high would the ball go in comparison to the tennis ball? Explain your answers.
- 5.15 (a) Calculate the kinetic energy, in joules, of a 1200-kg automobile moving at 18 m/s. (b) Convert this energy to calories.(c) What happens to this energy when the automobile brakes to a stop?
- 5.16 (a) A baseball weighs 5.13 oz. What is the kinetic energy, in joules, of this baseball when it is thrown by a major-league pitcher at 95.0 mi/h? (b) By what factor will the kinetic energy change if the speed of the baseball is decreased to 55.0 mi/h? (c) What happens to the kinetic energy when the baseball is caught by the catcher?

- 5.17 The use of the British thermal unit (Btu) is common in much engineering work. A Btu is the amount of heat required to raise the temperature of 1 lb of water by 1 °F. Calculate the number of joules in a Btu.
- **5.18** A watt is a measure of power (the rate of energy change) equal to 1 J/s. (a) Calculate the number of joules in a kilowatthour. (b) An adult person radiates heat to the surroundings at about the same rate as a 100-watt electric incandescent lightbulb. What is the total amount of energy in kcal radiated to the surroundings by an adult in 24 h?
- 5.19 (a) What is meant by the term *system* in thermodynamics?(b) What is a *closed system*? (c) What do we call the part of the universe that is not part of the system?
- 5.20 In a thermodynamic study a scientist focuses on the properties of a solution in an apparatus as illustrated. A solution is continuously flowing into the apparatus at the top and out at the bottom, such that the amount of solution in the apparatus is constant with time. (a) Is the solution in the apparatus a closed system, open system, or isolated system? Explain your choice. (b) If it is not a closed system, what could be done to make it a closed system?

- **5.21** Identify the force present and explain whether work is being performed in the following cases: (a) You lift a pencil off the top of a desk. (b) A spring is compressed to half its normal length.
- **5.22** Identify the force present and explain whether work is done when (a) a positively charged particle moves in a circle at a fixed distance from a negatively charged particle, (b) an iron nail is pulled off a magnet.

The First Law of Thermodynamics (Section 5.2)

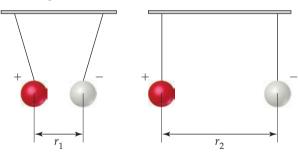

- **5.23** (a) State the first law of thermodynamics. (b) What is meant by the *internal energy* of a system? (c) By what means can the internal energy of a closed system increase?
- **5.24** (a) Write an equation that expresses the first law of thermodynamics in terms of heat and work. (b) Under what conditions will the quantities *q* and *w* be negative numbers?
- 5.25 Calculate ΔE and determine whether the process is endothermic or exothermic for the following cases: (a) q = 0.763 kJ and w = -840 J. (b) A system releases 66.1 kJ of heat to its surroundings while the surroundings do 44.0 kJ of work on the system.
- 5.26 For the following processes, calculate the change in internal energy of the system and determine whether the process is endothermic or exothermic: (a) A balloon is cooled by removing 0.655 kJ of heat. It shrinks on cooling, and the atmosphere does 382 J of work on the balloon. (b) A 100.0-g bar of gold is heated from 25 °C to 50 °C during which it absorbs 322 J of heat. Assume the volume of the gold bar remains constant.

5.27 A gas is confined to a cylinder fitted with a piston and an electrical heater, as shown here:

Suppose that current is supplied to the heater so that 100 J of energy is added. Consider two different situations. In case (1) the piston is allowed to move as the energy is added. In case (2) the piston is fixed so that it cannot move. (a) In which case does the gas have the higher temperature after addition of the electrical energy? Explain. (b) What can you say about the values of q and w in each case? (c) What can you say about the relative values of ΔE for the system (the gas in the cylinder) in the two cases?

5.28 Consider a system consisting of two oppositely charged spheres hanging by strings and separated by a distance r_1 , as shown in the accompanying illustration. Suppose they are separated to a larger distance r_2 , by moving them apart along a track. (a) What change, if any, has occurred in the potential energy of the system? (b) What effect, if any, does this process have on the value of ΔE ? (c) What can you say about q and w for this process?

- **5.29** (a) What is meant by the term *state function*? (b) Give an example of a quantity that is a state function and one that is not. (c) Is the volume of a system a state function? Why or why not?
- **5.30** Indicate which of the following is independent of the path by which a change occurs: (a) the change in potential energy when a book is transferred from table to shelf, (b) the heat evolved when a cube of sugar is oxidized to $CO_2(g)$ and $H_2O(g)$, (c) the work accomplished in burning a gallon of gasoline.

Enthalpy (Sections 5.3 and 5.4)

5.31 During a normal breath, our lungs expand about 0.50 L against an external pressure of 1.0 atm. How much work is involved in this process (in J)?

- **5.32** How much work (in J) is involved in a chemical reaction if the volume decreases from 5.00 to 1.26 L against a constant pressure of 0.857 atm?
- **5.33** (a) Why is the change in enthalpy usually easier to measure than the change in internal energy? (b) H is a state function, but q is not a state function. Explain. (c) For a given process at constant pressure, ΔH is positive. Is the process endothermic or exothermic?
- **5.34** (a) Under what condition will the enthalpy change of a process equal the amount of heat transferred into or out of the system? (b) During a constant-pressure process, the system releases heat to the surroundings. Does the enthalpy of the system increase or decrease during the process? (c) In a constant-pressure process, $\Delta H = 0$. What can you conclude about ΔE , q, and w?
- **5.35** Assume that the following reaction occurs at constant pressure:

$$2 \operatorname{Al}(s) + 3 \operatorname{Cl}_2(g) \longrightarrow 2 \operatorname{AlCl}_3(s)$$

- (a) If you are given ΔH for the reaction, what additional information do you need to determine ΔE for the process? (b) Which quantity is larger for this reaction? (c) Explain your answer to part (b).
- **5.36** Suppose that the gas-phase reaction $2 \text{ NO}(g) + \text{O}_2(g) \longrightarrow 2 \text{ NO}_2(g)$ were carried out in a constant-volume container at constant temperature. (a) Would the measured heat change represent ΔH or ΔE ? (b) If there is a difference, which quantity is larger for this reaction? (c) Explain your answer to part (b).
- **5.37** A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.4. When the gas undergoes a particular chemical reaction, it absorbs 824 J of heat from its surroundings and has 0.65 kJ of P-V work done on it by its surroundings. What are the values of ΔH and ΔE for this process?
- **5.38** A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.4. When 0.49 kJ of heat is added to the gas, it expands and does 214 J of work on the surroundings. What are the values of ΔH and ΔE for this process?
- **5.39** The complete combustion of ethanol, $C_2H_5OH(l)$, to form $H_2O(g)$ and $CO_2(g)$ at constant pressure releases 1235 kJ of heat per mole of C_2H_5OH . (a) Write a balanced thermochemical equation for this reaction. (b) Draw an enthalpy diagram for the reaction.
- **5.40** The decomposition of $Ca(OH)_2(s)$ into CaO(s) and $H_2O(g)$ at constant pressure requires the addition of 109 kJ of heat per mole of $Ca(OH)_2$. (a) Write a balanced thermochemical equation for the reaction. (b) Draw an enthalpy diagram for the reaction.
- **5.41** Ozone, $O_3(g)$, is a form of elemental oxygen that plays an important role in the absorption of ultraviolet radiation in the stratosphere. It decomposes to $O_2(g)$ at room temperature and pressure according to the following reaction:

$$2 O_3(g) \longrightarrow 3 O_2(g)$$
 $\Delta H = -284.6 \text{ kJ}$

- (a) What is the enthalpy change for this reaction per mole of O₃(g)?
- (b) Which has the higher enthalpy under these conditions, $2 O_3(g)$ or $3O_2(g)$?

5.43 Consider the following reaction:

$$2 \text{ Mg}(s) + O_2(g) \longrightarrow 2 \text{ MgO}(s) \quad \Delta H = -1204 \text{ kJ}$$

- (a) Is this reaction exothermic or endothermic?
- **(b)** Calculate the amount of heat transferred when 3.55 g of Mg(*s*) reacts at constant pressure.
- (c) How many grams of MgO are produced during an enthalpy change of -234 kJ?
- (d) How many kilojoules of heat are absorbed when 40.3 g of MgO(s) is decomposed into Mg(s) and O₂(g) at constant pressure?
- **5.44** Consider the following reaction:

$$2 \text{ CH}_3 \text{OH}(g) \longrightarrow 2 \text{ CH}_4(g) + \text{O}_2(g) \quad \Delta H = +252.8 \text{ kJ}$$

- (a) Is this reaction exothermic or endothermic? (b) Calculate the amount of heat transferred when 24.0 g of CH₃OH(g) is decomposed by this reaction at constant pressure. (c) For a given sample of CH₃OH, the enthalpy change during the reaction is 82.1 kJ. How many grams of methane gas are produced? (d) How many kilojoules of heat are released when 38.5 g of CH₄(g) reacts completely with O₂(g) to form CH₃OH(g) at constant pressure?
- **5.45** When solutions containing silver ions and chloride ions are mixed, silver chloride precipitates:

$$Ag^{+}(aq) + Cl^{-}(aq) \longrightarrow AgCl(s)$$
 $\Delta H = -65.5 \text{ kJ}$

- (a) Calculate ΔH for the production of 0.450 mol of AgCl by this reaction. (b) Calculate ΔH for the production of 9.00 g of AgCl. (c) Calculate ΔH when 9.25 \times 10⁻⁴ mol of AgCl dissolves in water.
- 5.46 At one time, a common means of forming small quantities of oxygen gas in the laboratory was to heat KClO₃:

$$2 \text{ KClO}_3(s) \longrightarrow 2 \text{ KCl}(s) + 3 \text{ O}_2(g) \quad \Delta H = -89.4 \text{ kJ}$$

For this reaction, calculate ΔH for the formation of (a) 1.36 mol of O_2 and (b) 10.4 g of KCl. (c) The decomposition of KClO₃ proceeds spontaneously when it is heated. Do you think that the reverse reaction, the formation of KClO₃ from KCl and O_2 , is likely to be feasible under ordinary conditions? Explain your answer.

5.47 Consider the combustion of liquid methanol, $CH_3OH(l)$:

$$\text{CH}_3\text{OH}(l) + \frac{3}{2}\,\text{O}_2(g) \longrightarrow \text{CO}_2(g) + 2\,\text{H}_2\text{O}(l)$$

$$\Delta H = -726.5\,\text{kJ}$$

(a) What is the enthalpy change for the reverse reaction?
(b) Balance the forward reaction with whole-number coefficients. What is ΔH for the reaction represented by this equation? (c) Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction?
(d) If the reaction were written to produce H₂O(g) instead of H₂O(l), would you expect the magnitude of ΔH to increase, decrease, or stay the same? Explain.

5.48 Consider the decomposition of liquid benzene, $C_6H_6(l)$, to gaseous acetylene, $C_2H_2(g)$:

$$C_6H_6(l) \longrightarrow 3 C_2H_2(g) \Delta H = +630 \text{ kJ}$$

- (a) What is the enthalpy change for the reverse reaction?
- (b) What is ΔH for the formation of 1 mol of acetylene?
- (c) Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction?
- (d) If $C_6H_6(g)$ were consumed instead of $C_6H_6(l)$, would you expect the magnitude of ΔH to increase, decrease, or stay the same? Explain.

Calorimetry (Section 5.5)

- **5.49** (a) What are the units of molar heat capacity? (b) What are the units of specific heat? (c) If you know the specific heat of copper, what additional information do you need to calculate the heat capacity of a particular piece of copper pipe?
- 5.50 Two solid objects, A and B, are placed in boiling water and allowed to come to the temperature of the water. Each is then lifted out and placed in separate beakers containing 1000 g water at 10.0 °C. Object A increases the water temperature by 3.50 °C; B increases the water temperature by 2.60 °C. (a) Which object has the larger heat capacity? (b) What can you say about the specific heats of A and B?
- **5.51** (a) What is the specific heat of liquid water? (b) What is the molar heat capacity of liquid water? (c) What is the heat capacity of 185 g of liquid water? (d) How many kJ of heat are needed to raise the temperature of 10.00 kg of liquid water from 24.6 to 46.2 °C?
- **5.52** (a) Which substance in Table 5.2 requires the smallest amount of energy to increase the temperature of 50.0 g of that substance by 10 K? (b) Calculate the energy needed for this temperature change.
- **5.53** The specific heat of octane, $C_8H_{18}(l)$, is 2.22 J/g-K. (a) How many J of heat are needed to raise the temperature of 80.0 g of octane from 10.0 to 25.0 °C? (b) Which will require more heat, increasing the temperature of 1 mol of $C_8H_{18}(l)$ by a certain amount or increasing the temperature of 1 mol of $H_2O(l)$ by the same amount?
- 5.54 Consider the data about gold metal in Exercise 5.26(b).(a) Based on the data, calculate the specific heat of Au(s).(b) Suppose that the same amount of heat is added to two 10.0-g blocks of metal, both initially at the same temperature. One block is gold metal, and one is iron metal. Which block will have the greater rise in temperature after the addition of the heat? (c) What is the molar heat capacity of Au(s)?
- 5.55 When a 6.50-g sample of solid sodium hydroxide dissolves in 100.0 g of water in a coffee-cup calorimeter (Figure 5.17), the temperature rises from 21.6 to 37.8 °C. (a) Calculate the quantity of heat (in kJ) released in the reaction. (b) Using your result from part (a), calculate ΔH (in kJ/mol NaOH) for the solution process. Assume that the specific heat of the solution is the same as that of pure water.
- **5.56** (a) When a 4.25-g sample of solid ammonium nitrate dissolves in 60.0 g of water in a coffee-cup calorimeter (Figure 5.17), the temperature drops from 22.0 to 16.9 °C. Calculate ΔH (in kJ/mol NH₄NO₃) for the solution process:

$$NH_4NO_3(s) \longrightarrow NH_4^+(aq) + NO_3^-(aq)$$

Assume that the specific heat of the solution is the same as that of pure water. (b) Is this process endothermic or exothermic?

- 5.57 A 2.200-g sample of quinone ($C_6H_4O_2$) is burned in a bomb calorimeter whose total heat capacity is 7.854 kJ/°C. The temperature of the calorimeter increases from 23.44 to 30.57 °C. What is the heat of combustion per gram of quinone? Per mole of quinone?
- **5.58** A 1.800-g sample of phenol (C_6H_5OH) was burned in a bomb calorimeter whose total heat capacity is 11.66 kJ/°C. The temperature of the calorimeter plus contents increased from 21.36 to 26.37 °C. (a) Write a balanced chemical equation for the bomb calorimeter reaction. (b) What is the heat of combustion per gram of phenol? Per mole of phenol?
- **5.59** Under constant-volume conditions, the heat of combustion of glucose ($C_6H_{12}O_6$) is 15.57 kJ/g. A 3.500-g sample of glucose is burned in a bomb calorimeter. The temperature of the calorimeter increases from 20.94 to 24.72 °C. (a) What is the total heat capacity of the calorimeter? (b) If the size of the glucose sample had been exactly twice as large, what would the temperature change of the calorimeter have been?
- **5.60** Under constant-volume conditions, the heat of combustion of benzoic acid (C_6H_5COOH) is 26.38 kJ/g. A 2.760-g sample of benzoic acid is burned in a bomb calorimeter. The temperature of the calorimeter increases from 21.60 to 29.93 °C. (a) What is the total heat capacity of the calorimeter? (b) A 1.440-g sample of a new organic substance is combusted in the same calorimeter. The temperature of the calorimeter increases from 22.14 to 27.09 °C. What is the heat of combustion per gram of the new substance? (c) Suppose that in changing samples, a portion of the water in the calorimeter were lost. In what way, if any, would this change the heat capacity of the calorimeter?

Hess's Law (Section 5.6)

- **5.61** What is the connection between Hess's law and the fact that *H* is a state function?
- **5.62** Consider the following hypothetical reactions:

A
$$\longrightarrow$$
 B $\Delta H = +30 \text{ kJ}$
B \longrightarrow C $\Delta H = +60 \text{ kJ}$

- (a) Use Hess's law to calculate the enthalpy change for the reaction A \longrightarrow C.
- (b) Construct an enthalpy diagram for substances A, B, and C, and show how Hess's law applies.
- **5.63** Calculate the enthalpy change for the reaction

$$P_4O_6(s) + 2 O_2(g) \longrightarrow P_4O_{10}(s)$$

given the following enthalpies of reaction:

$$P_4(s) + 3 O_2(g) \longrightarrow P_4O_6(s)$$
 $\Delta H = -1640.1 \text{ kJ}$
 $P_4(s) + 5 O_2(g) \longrightarrow P_4O_{10}(s)$ $\Delta H = -2940.1 \text{ kJ}$

5.64 From the enthalpies of reaction

$$2 C(s) + O_2(g) \longrightarrow 2 CO(g) \Delta H = -221.0 \text{ kJ}$$

 $2 C(s) + O_2(g) + 4 H_2(g) \longrightarrow 2 CH_3OH(g) \Delta H = -402.4 \text{ kJ}$

calculate ΔH for the reaction

$$CO(g) + 2 H_2(g) \longrightarrow CH_3OH(g)$$

5.65 From the enthalpies of reaction

$$\begin{array}{ll} H_2(g) \, + \, F_2(g) & \longrightarrow \, 2 \, HF(g) & \Delta H = \, -537 \, kJ \\ C(s) \, + \, 2 \, F_2(g) & \longrightarrow \, CF_4(g) & \Delta H = \, -680 \, kJ \\ 2 \, C(s) \, + \, 2 \, H_2(g) & \longrightarrow \, C_2 H_4(g) & \Delta H = \, +52.3 \, kJ \end{array}$$

calculate ΔH for the reaction of ethylene with F_2 :

$$C_2H_4(g) + 6F_2(g) \longrightarrow 2CF_4(g) + 4HF(g)$$

5.66 Given the data

$$\begin{array}{cccc} \mathrm{N_2}(g) + \mathrm{O_2}(g) & \longrightarrow & 2 \ \mathrm{NO}(g) & \Delta H = +180.7 \ \mathrm{kJ} \\ 2 \ \mathrm{NO}(g) + \mathrm{O_2}(g) & \longrightarrow & 2 \ \mathrm{NO_2}(g) & \Delta H = -113.1 \ \mathrm{kJ} \\ 2 \ \mathrm{N_2O}(g) & \longrightarrow & 2 \ \mathrm{N_2}(g) + \mathrm{O_2}(g) & \Delta H = -163.2 \ \mathrm{kJ} \end{array}$$

use Hess's law to calculate ΔH for the reaction

$$N_2O(g) + NO_2(g) \longrightarrow 3NO(g)$$

Enthalpies of Formation (Section 5.7)

- **5.67** (a) What is meant by the term *standard conditions* with reference to enthalpy changes? (b) What is meant by the term *enthalpy of formation*? (c) What is meant by the term *standard enthalpy of formation*?
- **5.68** (a) Why are tables of standard enthalpies of formation so useful? (b) What is the value of the standard enthalpy of formation of an element in its most stable form? (c) Write the chemical equation for the reaction whose enthalpy change is the standard enthalpy of formation of sucrose (table sugar), $C_{12}H_{22}O_{11}(s)$, $\Delta H_f^{\circ}[C_{12}H_{22}O_{11}]$.
- 5.69 For each of the following compounds, write a balanced thermochemical equation depicting the formation of one mole of the compound from its elements in their standard states and then look up ΔH_f° for each substance in Appendix C. (a) NO₂(g), (b) SO₃(g), (c) NaBr(s), (d) Pb(NO₃)₂(s).
- **5.70** Write balanced equations that describe the formation of the following compounds from elements in their standard states, and then look up the standard enthalpy of formation for each substance in Appendix C: (a) H₂O₂(g), (b) CaCO₃(s), (c) POCl₃(l), (d) C₂H₅OH(l).
- **5.71** The following is known as the thermite reaction:

$$2 \operatorname{Al}(s) + \operatorname{Fe}_2 \operatorname{O}_3(s) \longrightarrow \operatorname{Al}_2 \operatorname{O}_3(s) + 2 \operatorname{Fe}(s)$$

This highly exothermic reaction is used for welding massive units, such as propellers for large ships. Using standard enthalpies of formation in Appendix C, calculate ΔH° for this reaction

- **5.72** Many portable gas heaters and grills use propane, $C_3H_8(g)$, as a fuel. Using standard enthalpies of formation, calculate the quantity of heat produced when 10.0 g of propane is completely combusted in air under standard conditions.
- **5.73** Using values from Appendix C, calculate the standard enthalpy change for each of the following reactions:

(a)
$$2 SO_2(g) + O_2(g) \longrightarrow 2 SO_3(g)$$

(b)
$$Mg(OH)_2(s) \longrightarrow MgO(s) + H_2O(l)$$

(c)
$$N_2O_4(g) + 4H_2(g) \longrightarrow N_2(g) + 4H_2O(g)$$

(d)
$$SiCl_4(l) + 2 H_2O(l) \longrightarrow SiO_2(s) + 4 HCl(g)$$

5.74 Using values from Appendix C, calculate the value of ΔH° for each of the following reactions:

(a)
$$CaO(s) + 2 HCl(g) \longrightarrow CaCl_2(s) + H_2O(g)$$

(b)
$$4 \operatorname{FeO}(s) + O_2(g) \longrightarrow 2 \operatorname{Fe}_2O_3(s)$$

(c)
$$2 \operatorname{CuO}(s) + \operatorname{NO}(g) \longrightarrow \operatorname{Cu}_2\operatorname{O}(s) + \operatorname{NO}_2(g)$$

(d)
$$4 \text{ NH}_3(g) + O_2(g) \longrightarrow 2 \text{ N}_2 H_4(g) + 2 \text{ H}_2 O(l)$$

5.75 Complete combustion of 1 mol of acetone (C_3H_6O) liberates 1790 kJ:

$$C_3H_6O(l) + 4 O_2(g) \longrightarrow 3 CO_2(g) + 3 H_2O(l)$$

 $\Delta H^{\circ} = -1790 \text{ kJ}$

Using this information together with the standard enthalpies of formation of $O_2(g)$, $CO_2(g)$, and $H_2O(l)$ from Appendix C, calculate the standard enthalpy of formation of acetone.

5.76 Calcium carbide (CaC_2) reacts with water to form acetylene (C_2H_2) and $Ca(OH)_2$. From the following enthalpy of reaction data and data in Appendix C, calculate ΔH_f° for $CaC_2(s)$:

$$CaC_2(s) + 2 H_2O(l) \longrightarrow Ca(OH)_2(s) + C_2H_2(g)$$

 $\Delta H^{\circ} = -127.2 \text{ kJ}$

5.77 Gasoline is composed primarily of hydrocarbons, including many with eight carbon atoms, called *octanes*. One of the cleanest-burning octanes is a compound called 2,3,4-trimethylpentane, which has the following structural formula:

The complete combustion of one mole of this compound to $CO_2(g)$ and $H_2O(g)$ leads to $\Delta H^\circ = -5064.9 \, \text{kJ/mol.}$ (a) Write a balanced equation for the combustion of 1 mol of $C_8H_{18}(l)$. (b) By using the information in this problem and data in Table 5.3, calculate ΔH_f° for 2,3,4-trimethylpentane.

5.78 Diethyl ether, $C_4H_{10}O(l)$, a flammable compound that has long been used as a surgical anesthetic, has the structure

The complete combustion of 1 mol of $C_4H_{10}O(l)$ to $CO_2(g)$ and $H_2O(l)$ yields $\Delta H^\circ = -2723.7$ kJ. (a) Write a balanced equation for the combustion of 1 mol of $C_4H_{10}O(l)$. (b) By using the information in this problem and data in Table 5.3, calculate ΔH_l° for diethyl ether.

- 5.79 Ethanol (C₂H₅OH) is currently blended with gasoline as an automobile fuel. (a) Write a balanced equation for the combustion of liquid ethanol in air. (b) Calculate the standard enthalpy change for the reaction, assuming H₂O(g) as a product. (c) Calculate the heat produced per liter of ethanol by combustion of ethanol under constant pressure. Ethanol has a density of 0.789 g/mL. (d) Calculate the mass of CO₂ produced per kJ of heat emitted.
- **5.80** Methanol (CH₃OH) is used as a fuel in race cars. (a) Write a balanced equation for the combustion of liquid methanol in air. (b) Calculate the standard enthalpy change for the reaction, assuming $H_2O(g)$ as a product. (c) Calculate the heat produced by combustion per liter of methanol. Methanol has a density of 0.791 g/mL. (d) Calculate the mass of CO_2 produced per kJ of heat emitted.

Foods and Fuels (Section 5.8)

- **5.81** (a) What is meant by the term *fuel value*? (b) Which is a greater source of energy as food, 5 g of fat or 9 g of carbohydrate? (c) The metabolism of glucose produces CO₂(g) and H₂O(l). How does the human body expel these reaction products?
- **5.82** (a) Why are fats well suited for energy storage in the human body? (b) A particular chip snack food is composed of 12% protein, 14% fat, and the rest carbohydrate. What percentage of the calorie content of this food is fat? (c) How many grams of protein provide the same fuel value as 25 g of fat?
- **5.83** (a) A serving of a particular ready-to-serve chicken noodle soup contains 2.5 g fat, 14 g carbohydrate, and 7 g protein. Estimate the number of Calories in a serving. (b) According to its nutrition label, the same soup also contains 690 mg of sodium. Do you think the sodium contributes to the caloric content of the soup?
- **5.84** A pound of plain M&M® candies contains 96 g fat, 320 g carbohydrate, and 21 g protein. What is the fuel value in kJ in a 42-g (about 1.5 oz) serving? How many Calories does it provide?
- **5.85** The heat of combustion of fructose, $C_6H_{12}O_6$, is -2812 kJ/mol. If a fresh golden delicious apple weighing 4.23 oz (120 g) contains 16.0 g of fructose, what caloric content does the fructose contribute to the apple?
- **5.86** The heat of combustion of ethanol, $C_2H_5OH(l)$, is -1367 kJ/mol. A batch of Sauvignon Blanc wine contains 10.6% ethanol by mass. Assuming the density of the wine to be 1.0 g/mL, what is the caloric content due to the alcohol (ethanol) in a 6-oz glass of wine (177 mL)?
- **5.87** The standard enthalpies of formation of gaseous propyne (C_3H_4) , propylene (C_3H_6) , and propane (C_3H_8) are +185.4, +20.4, and -103.8 kJ/mol, respectively. (a) Calculate the heat evolved per mole on combustion of each substance to yield $CO_2(g)$ and $H_2O(g)$. (b) Calculate the heat evolved on combustion of 1 kg of each substance. (c) Which is the most efficient fuel in terms of heat evolved per unit mass?
- **5.88** It is interesting to compare the "fuel value" of a hydrocarbon in a world where oxygen is the combustion agent. The enthalpy of formation of $CF_4(g)$ is -679.9 kJ/mol. Which of the following two reactions is the more exothermic?

$$CH_4(g) + 2 O_2(g) \longrightarrow CO_2(g) + 2 H_2O(g)$$

 $CH_4(g) + 4 F_2(g) \longrightarrow CF_4(g) + 4 HF(g)$

5.89 At the end of 2012, global population was about 7.0 billion people. What mass of glucose in kg would be needed to provide 1500 cal/person/day of nourishment to the global population for one year? Assume that glucose is metabolized entirely to $CO_2(g)$ and $H_2O(l)$ according to the following thermochemical equation:

$${
m C_6H_{12}O_6}(s)+6~{
m O_2}(g)\longrightarrow 6~{
m CO_2}(g)+6~{
m H_2O}(l)$$

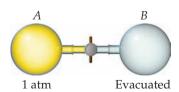

$$\Delta H^\circ=-2803~{
m kJ}$$

5.90 The automobile fuel called E85 consists of 85% ethanol and 15% gasoline. E85 can be used in the so-called flex-fuel vehicles (FFVs), which can use gasoline, ethanol, or a mix as fuels. Assume that gasoline consists of a mixture of octanes (different isomers of C_8H_{18}), that the average heat of combustion of $C_8H_{18}(l)$ is 5400 kJ/mol, and that gasoline has an average

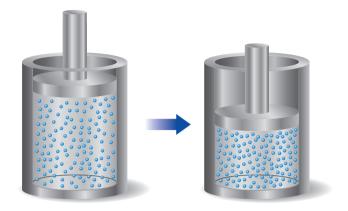

density of 0.70 g/mL. The density of ethanol is 0.79 g/mL. (a) By using the information given as well as data in Appendix C, compare the energy produced by combustion of 1.0 L of gasoline and of 1.0 L of ethanol. (b) Assume that the density and heat of combustion of E85 can be obtained by using 85% of the values for ethanol and 15% of the values for gasoline. How much energy could be released by the combustion of 1.0 L of E85? (c) How many gallons of E85 would be needed to provide the same energy as 10 gal of gasoline? (d) If gasoline costs \$3.88 per gallon in the United States, what is the break-even price per gallon of E85 if the same amount of energy is to be delivered?

Additional Exercises

- 5.91 At 20 °C (approximately room temperature) the average velocity of N₂ molecules in air is 1050 mph. (a) What is the average speed in m/s? (b) What is the kinetic energy (in J) of an N_2 molecule moving at this speed? (c) What is the total kinetic energy of 1 mol of N₂ molecules moving at this speed?
- 5.92 Suppose an Olympic diver who weighs 52.0 kg executes a straight dive from a 10-m platform. At the apex of the dive, the diver is 10.8 m above the surface of the water. (a) What is the potential energy of the diver at the apex of the dive, relative to the surface of the water? (b) Assuming that all the potential energy of the diver is converted into kinetic energy at the surface of the water, at what speed, in m/s, will the diver enter the water? (c) Does the diver do work on entering the water? Explain.
- **5.93** The air bags that provide protection in automobiles in the event of an accident expand because of a rapid chemical reaction. From the viewpoint of the chemical reactants as the system, what do you expect for the signs of q and w in this process?
- **5.94** An aluminum can of a soft drink is placed in a freezer. Later, you find that the can is split open and its contents frozen. Work was done on the can in splitting it open. Where did the energy for this work come from?
- 5.95 Consider a system consisting of the following apparatus, in which gas is confined in one flask and there is a vacuum in the other flask. The flasks are separated by a valve. Assume that the flasks are perfectly insulated and will not allow the flow of heat into or out of the flasks to the surroundings. When the valve is opened, gas flows from the filled flask to the evacuated one. (a) Is work performed during the expansion of the gas? (b) Why or why not? (c) Can you determine the value of ΔE for the process?

5.96 A sample of gas is contained in a cylinder-and-piston arrangement. It undergoes the change in state shown in the drawing. (a) Assume first that the cylinder and piston are perfect thermal insulators that do not allow heat to be transferred. What is the value of *q* for the state change? What is the sign of w for the state change? What can be said about ΔE for the state change? (b) Now assume that the cylinder and piston are made up of a thermal conductor such as a metal. During the state change, the cylinder gets warmer to the touch. What is the sign of q for the state change in this case? Describe the difference in the state of the system at the end of the process in the two cases. What can you say about the relative values of ΔE ?

5.97 Limestone stalactites and stalagmites are formed in caves by the following reaction:

$$Ca^{2+}(aq) + 2 HCO_3^{-}(aq) \longrightarrow CaCO_3(s) + CO_2(g) + H_2O(l)$$

If 1 mol of CaCO₃ forms at 298 K under 1 atm pressure, the reaction performs 2.47 kJ of P-V work, pushing back the atmosphere as the gaseous CO2 forms. At the same time, 38.95 kJ of heat is absorbed from the environment. What are the values of ΔH and of ΔE for this reaction?

- 5.98 Consider the systems shown in Figure 5.10. In one case the battery becomes completely discharged by running the current through a heater and in the other case by running a fan. Both processes occur at constant pressure. In both cases the change in state of the system is the same: The battery goes from being fully charged to being fully discharged. Yet in one case the heat evolved is large, and in the other it is small. Is the enthalpy change the same in the two cases? If not, how can enthalpy be considered a state function? If it is, what can you say about the relationship between enthalpy change and q in this case, as compared with others that we have considered?
- **5.99** A house is designed to have passive solar energy features. Brickwork incorporated into the interior of the house acts as a heat absorber. Each brick weighs approximately 1.8 kg. The specific heat of the brick is 0.85 J/g-K. How many bricks must be incorporated into the interior of the house to provide the same total heat capacity as 1.7×10^3 gal of water?
- 5.100 A coffee-cup calorimeter of the type shown in Figure 5.17 contains 150.0 g of water at 25.1 °C. A 121.0-g block of copper metal is heated to 100.4 °C by putting it in a beaker of boiling water. The specific heat of Cu(s) is 0.385 J/g-K. The Cu is added to the calorimeter, and after a time the contents of the cup reach a constant temperature of 30.1 °C. (a) Determine the amount of heat, in J, lost by the copper block. (b) Determine the amount of heat gained by the water. The specific heat of water is 4.18 J/g-K. (c) The difference between your answers for (a) and (b) is due to heat loss through the Styrofoam® cups and the heat necessary to raise the temperature of the inner wall of the apparatus. The heat capacity of the calorimeter is the amount of heat necessary to raise the temperature of the apparatus (the cups and the

stopper) by 1 K. Calculate the heat capacity of the calorimeter in J/K. (d) What would be the final temperature of the system if all the heat lost by the copper block were absorbed by the water in the calorimeter?

- **5.101** (a) When a 0.235-g sample of benzoic acid is combusted in a bomb calorimeter (Figure 5.18), the temperature rises 1.642 °C. When a 0.265-g sample of caffeine, $C_8H_{10}O_2N_4$, is burned, the temperature rises 1.525 °C. Using the value 26.38 kJ/g for the heat of combustion of benzoic acid, calculate the heat of combustion per mole of caffeine at constant volume. (b) Assuming that there is an uncertainty of 0.002 °C in each temperature reading and that the masses of samples are measured to 0.001 g, what is the estimated uncertainty in the value calculated for the heat of combustion per mole of caffeine?
- 5.102 Meals-ready-to-eat (MREs) are military meals that can be heated on a flameless heater. The heat is produced by the following reaction:

$$Mg(s) + 2 H_2O(l) \longrightarrow Mg(OH)_2(s) + 2H_2(g)$$

- (a) Calculate the standard enthalpy change for this reaction. (b) Calculate the number of grams of Mg needed for this reaction to release enough energy to increase the temperature of 75 mL of water from 21 to 79 °C.
- **5.103** Burning methane in oxygen can produce three different carbon-containing products: soot (very fine particles of graphite), CO(g), and $CO_2(g)$. (a) Write three balanced equations for the reaction of methane gas with oxygen to produce these three products. In each case assume that $H_2O(l)$ is the only other product. (b) Determine the standard enthalpies for the reactions in part (a). (c) Why, when the oxygen supply is adequate, is $CO_2(g)$ the predominant carbon-containing product of the combustion of methane?
- 5.104 We can use Hess's law to calculate enthalpy changes that cannot be measured. One such reaction is the conversion of methane to ethylene:

$$2 CH_4(g) \longrightarrow C_2H_4(g) + H_2(g)$$

Calculate the ΔH° for this reaction using the following thermochemical data:

$$\begin{array}{lll} {\rm CH_4}(g) + 2\,{\rm O_2}(g) & \longrightarrow {\rm CO_2}(g) + 2\,{\rm H_2O}(l) & \Delta H^\circ = -890.3\,{\rm kJ} \\ {\rm C_2H_4}(g) + {\rm H_2}(g) & \longrightarrow {\rm C_2H_6}(g) & \Delta H^\circ = -136.3\,{\rm kJ} \\ 2\,{\rm H_2}(g) + {\rm O_2}(g) & \longrightarrow 2\,{\rm H_2O}(l) & \Delta H^\circ = -571.6\,{\rm kJ} \\ 2\,{\rm C_2H_6}(g) + 7\,{\rm O_2}(g) & \longrightarrow 4\,{\rm CO_2}(g) + 6\,{\rm H_2O}(l) & \Delta H^\circ = -3120.8\,{\rm kJ} \end{array}$$

5.105 From the following data for three prospective fuels, calculate which could provide the most energy per unit volume:

Fuel	Density at 20 °C (g/cm ³)	Molar Enthalpy of Combustion (kJ/mol)
Nitroethane, $C_2H_5NO_2(l)$	1.052	-1368
Ethanol, $C_2H_5OH(l)$	0.789	-1367
Methylhydrazine, $CH_6N_2(l)$	0.874	-1307

5.106 The hydrocarbons acetylene (C_2H_2) and benzene (C_6H_6) have the same empirical formula. Benzene is an "aromatic" hydrocarbon, one that is unusually stable because of its structure. (a) By using data in Appendix C, determine the standard enthalpy change for the reaction $3 C_2H_2(g) \longrightarrow C_6H_6(l)$.

- (b) Which has greater enthalpy, 3 mol of acetylene gas or 1 mol of liquid benzene? (c) Determine the fuel value, in kJ/g, for acetylene and benzene.
- 5.107 Ammonia (NH₃) boils at $-33\,^{\circ}$ C; at this temperature it has a density of $0.81\,\mathrm{g/cm^3}$. The enthalpy of formation of NH₃(g) is $-46.2\,\mathrm{kJ/mol}$, and the enthalpy of vaporization of NH₃(l) is $23.2\,\mathrm{kJ/mol}$. Calculate the enthalpy change when 1 L of liquid NH₃ is burned in air to give N₂(g) and H₂O(g). How does this compare with ΔH for the complete combustion of 1 L of liquid methanol, CH₃OH(l)? For CH₃OH(l), the density at 25 °C is $0.792\,\mathrm{g/cm^3}$, and $\Delta H_f^{\circ} = -239\,\mathrm{kJ/mol}$.
- **5.108** Three common hydrocarbons that contain four carbons are listed here, along with their standard enthalpies of formation:

Hydrocarbon	Formula	$\Delta H_f^{\circ}(kJ/mol)$
1,3-Butadiene	$C_4H_6(g)$	111.9
1-Butene	$C_4H_8(g)$	1.2
<i>n</i> -Butane	$C_4H_{10}(g)$	-124.7

- (a) For each of these substances, calculate the molar enthalpy of combustion to $CO_2(g)$ and $H_2O(l)$. (b) Calculate the fuel value, in kJ/g, for each of these compounds. (c) For each hydrocarbon, determine the percentage of hydrogen by mass. (d) By comparing your answers for parts (b) and (c), propose a relationship between hydrogen content and fuel value in hydrocarbons.
- 5.109 A 200-lb man decides to add to his exercise routine by walking up three flights of stairs (45 ft) 20 times per day. He figures that the work required to increase his potential energy in this way will permit him to eat an extra order of French fries, at 245 Cal, without adding to his weight. Is he correct in this assumption?
- **5.110** The Sun supplies about 1.0 kilowatt of energy for each square meter of surface area ($1.0\,\mathrm{kW/m^2}$, where a watt = $1\,\mathrm{J/s}$). Plants produce the equivalent of about 0.20 g of sucrose ($\mathrm{C_{12}H_{22}O_{11}}$) per hour per square meter. Assuming that the sucrose is produced as follows, calculate the percentage of sunlight used to produce sucrose.

$$12 \text{ CO}_2(g) + 11 \text{ H}_2\text{O}(l) \longrightarrow \text{ C}_{12}\text{H}_{22}\text{O}_{11} + 12 \text{ O}_2(g)$$

$$\Delta H = 5645 \text{ kJ}$$

5.111 It is estimated that the net amount of carbon dioxide fixed by photosynthesis on the landmass of Earth is $5.5 \times 10^{16} \, \mathrm{g/yr}$ of CO_2 . Assume that all this carbon is converted into glucose. (a) Calculate the energy stored by photosynthesis on land per year, in kJ. (b) Calculate the average rate of conversion of solar energy into plant energy in megawatts, MW $(1W = 1 \, \mathrm{J/s})$. A large nuclear power plant produces about $10^3 \, \mathrm{MW}$. The energy of how many such nuclear power plants is equivalent to the solar energy conversion?

Integrative Exercises

5.112 Consider the combustion of a single molecule of $\operatorname{CH}_4(g)$, forming $\operatorname{H}_2\operatorname{O}(l)$ as a product. (a) How much energy, in J, is produced during this reaction? (b) A typical X-ray light source has an energy of 8 keV. How does the energy of combustion compare to the energy of the X-ray?

5.113 Consider the following unbalanced oxidation-reduction reactions in aqueous solution:

$$Ag^{+}(aq) + Li(s) \longrightarrow Ag(s) + Li^{+}(aq)$$

 $Fe(s) + Na^{+}(aq) \longrightarrow Fe^{2+}(aq) + Na(s)$
 $K(s) + H_2O(l) \longrightarrow KOH(aq) + H_2(g)$

- (a) Balance each of the reactions. (b) By using data in Appendix C, calculate ΔH° for each of the reactions. (c) Based on the values you obtain for ΔH° , which of the reactions would you expect to be thermodynamically favored? (d) Use the activity series to predict which of these reactions should occur. ∞ (Section 4.4) Are these results in accord with your conclusion in part (c) of this problem?
- **5.114** Consider the following acid-neutralization reactions involving the strong base NaOH(*aq*):

$$HNO_3(aq) + NaOH(aq) \longrightarrow NaNO_3(aq) + H_2O(l)$$

 $HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$
 $NH_4^+(aq) + NaOH(aq) \longrightarrow NH_3(aq) + Na^+(aq) + H_2O(l)$

- (a) By using data in Appendix C, calculate ΔH° for each of the reactions. (b) As we saw in Section 4.3, nitric acid and hydrochloric acid are strong acids. Write net ionic equations for the neutralization of these acids. (c) Compare the values of ΔH° for the first two reactions. What can you conclude? (d) In the third equation $\mathrm{NH_4}^+(aq)$ is acting as an acid. Based on the value of ΔH° for this reaction, do you think it is a strong or a weak acid? Explain.
- 5.115 Consider two solutions, the first being 50.0 mL of 1.00 *M* CuSO₄ and the second 50.0 mL of 2.00 *M* KOH. When the two solutions are mixed in a constant-pressure calorimeter, a precipitate forms and the temperature of the mixture rises from 21.5 to 27.7 °C. (a) Before mixing, how many grams of Cu are present in the solution of CuSO₄? (b) Predict the identity of the precipitate in the reaction. (c) Write complete and net ionic equations for the reaction that occurs when the two solutions are mixed. (d) From the calorimetric data, calculate Δ*H* for the reaction that occurs on mixing. Assume that the calorimeter absorbs only a negligible quantity of heat, that the total volume of the solution is 100.0 mL, and that the specific heat and density of the solution after mixing are the same as those of pure water.
- **5.116** The precipitation reaction between $AgNO_3(aq)$ and NaCl(aq) proceeds as follows:

$$AgNO_3(aq) + NaCl(aq) \longrightarrow NaNO_3(aq) + AgCl(s)$$

- (a) By using data in Appendix C, calculate ΔH° for the net ionic equation of this reaction. (b) What would you expect for the value of ΔH° of the overall molecular equation compared to that for the net ionic equation? Explain. (c) Use the results from (a) and (b) along with data in Appendix C to determine the value of ΔH_f° for AgNO₃(aq).
- 5.117 A sample of a hydrocarbon is combusted completely in O₂(g) to produce 21.83 g CO₂(g), 4.47 g H₂O(g), and 311 kJ of heat. (a) What is the mass of the hydrocarbon sample that was combusted? (b) What is the empirical formula of the hydrocarbon? (c) Calculate the value of ΔH_f° per empirical-formula unit of the hydrocarbon. (d) Do you think that the hydrocarbon is one of those listed in Appendix C? Explain your answer.
- 5.118 The methane molecule, CH₄, has the geometry shown in Figure 2.17. Imagine a hypothetical process in which the methane molecule is "expanded," by simultaneously extending all four C—H bonds to infinity. We then have the process

$$CH_4(g) \longrightarrow C(g) + 4H(g)$$

- (a) Compare this process with the reverse of the reaction that represents the standard enthalpy of formation of $CH_4(g)$. (b) Calculate the enthalpy change in each case. Which is the more endothermic process? What accounts for the difference in ΔH° values? (c) Suppose that 3.45 g $CH_4(g)$ reacts with 1.22 g $F_2(g)$, forming $CH_4(g)$ and HF(g) as sole products. What is the limiting reagent in this reaction? If the reaction occurs at constant pressure, what amount of heat is evolved?
- 5.119 World energy supplies are often measured in the unit of quadrillion British thermal units (1012 Btu), generally called a "quad." In 2015, world energy consumption is projected to be 5.81×10^{17} kJ. (a) With reference to Exercise 5.17, how many quads of energy does this quantity represent? (b) Current annual energy consumption in the United States is 99.5 quads. Assume that all this energy is to be generated by burning $CH_4(g)$ in the form of natural gas. If the combustion of the $CH_4(g)$ were complete and 100% efficient, how many moles of $CH_4(g)$ would need to be combusted to provide the U.S. energy demand? (c) How many kilograms of $CO_2(g)$ would be generated in the combustion in part (b)? (d) Compare your answer to part (c) with information given in Exercise 5.111. Do you think that photosynthesis is an adequate means to maintain a stable level of CO2 in the atmosphere?

Design an Experiment

One of the important ideas of thermodynamics is that energy can be transferred in the form of heat or work. Imagine that you lived 150 years ago when the relationships between heat and work were not well understood. You have formulated a hypothesis that work can be converted to heat with the same amount of work always generating the same amount of heat. To test this idea, you have designed an experiment using a device in which a falling weight is connected through pulleys to a shaft with an attached paddle wheel that is immersed in water. This is actually a classic experiment performed by James Joule in the 1840s. You can see various images of Joule's apparatus by Googling "Joule experiment images."

(a) Using this device, what measurements would you need to make to test your hypothesis? (b) What equations would you use in analyzing your experiment? (c) Do you think you could obtain a reasonable result from a single experiment? Why or why not? (d) In what way could the precision of your instruments affect the conclusions that you make? (e) List ways that you could modify the equipment to improve the data you obtain if you were performing this experiment today instead of 150 years ago. (f) Give an example of how you could demonstrate the relationship between heat and a form of energy other than mechanical work.

Electronic Structure of Atoms

The beginning of the twentieth century was truly one of the most revolutionary periods of scientific discovery. Two theoretical developments caused dramatic changes in our view of the universe. The first, Einstein's theory of relativity, forever changed our views of the relationships between space and time. The second—which will be the focus of this chapter—is the *quantum theory*, which explains much of the behavior of electrons in atoms.

The quantum theory has led to the explosion in technological developments in the twentieth century, including remarkable new light sources, such as light-emitting diodes (LEDs) that are now being used as high-quality, low-energy-consumption light sources in many applications, and lasers, which have revolutionized so many aspects of our lives. The quantum theory also led to the development of the solid-state electronics that has allowed computers, cellular telephones, and countless other electronic devices to transform our daily lives.

In this chapter we explore the quantum theory and its importance in chemistry. We begin by looking at the nature of light and how our description of light was changed by the quantum theory. We will explore some of the tools used in *quantum mechanics*, the "new" physics that had to be developed to describe atoms correctly. We will then use the quantum theory to describe the arrangements of electrons in atoms—what we call the **electronic structure** of atoms. The electronic structure of an atom refers to the number of electrons in the atom as well as their distribution around the nucleus and their energies. We will see that the quantum description of the electronic structure of atoms helps us to understand the arrangement of the elements in the periodic table—why, for example, helium and neon are both unreactive gases, whereas sodium and potassium are both soft, reactive metals.

➤ A LASER LIGHTSHOW at an entertainment event. Lasers produce light with very specific colors because of step-like energy transitions by electrons in the laser materials.

6.1 THE WAVE NATURE OF LIGHT We learn that light (radiant energy, or *electromagnetic radiation*) has wave-like properties and is characterized by *wavelength*, *frequency*, and *speed*.

6.2 QUANTIZED ENERGY AND PHOTONS From studies of the radiation given off by hot objects and of the interaction of light with metal surfaces, we recognize that electromagnetic radiation also has particle-like properties and can be described as *photons*, "particles" of light.

6.3 LINE SPECTRA AND THE BOHR MODEL We examine the light emitted by electrically excited atoms (*line spectra*). Line spectra indicate that there are only certain energy levels that are allowed for electrons in atoms and that energy is involved when an electron jumps from one level to another. The Bohr model of the atom pictures the electrons moving only in certain allowed orbits around the nucleus.

6.4 THE WAVE BEHAVIOR OF MATTER We recognize that matter also has wave-like properties. As a result, it is impossible to determine simultaneously the exact position and the exact momentum of an electron in an atom (*Heisenberg's uncertainty principle*).

6.5 QUANTUM MECHANICS AND ATOMIC ORBITALS We can describe how the electron exists in the hydrogen atom by treating it as if it were a wave. The *wave functions* that mathematically describe the electron's position and energy in an atom are called *atomic orbitals*. Each orbital is characterized by a set of *quantum numbers*.

6.6 REPRESENTATIONS OF ORBITALS We consider the three-dimensional shapes of orbitals and how they can be represented by graphs of electron density.

6.7 MANY-ELECTRON ATOMS We learn that the energy levels of an atom having more than one electron are different from those of the hydrogen atom. In addition, we learn that each electron has an additional quantum-mechanical property called *spin*. The *Pauli*

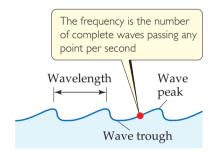

exclusion principle states that no two electrons in an atom can have the same four quantum numbers (three for the orbital and one for the spin). Therefore, each orbital can hold a maximum of two electrons.

6.8 ELECTRON CONFIGURATIONS We learn how the orbitals of the hydrogen atom can be used to describe the arrangements of electrons in many-electron atoms. Using patterns in orbital energies as well as some fundamental characteristics of electrons described by *Hund's rule*, we determine how electrons are distributed among the orbitals (*electron configurations*).

6.9 ELECTRON CONFIGURATIONS AND THE PERIODIC TABLE We observe that the electron configuration of an atom is related to the location of the element in the periodic table.

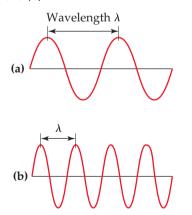

▲ Figure 6.1 Water waves. The movement of a boat through the water forms waves. The regular variation of peaks and troughs enables us to sense the motion of the waves away from the boat.

▲ Figure 6.2 Water waves. The wavelength is the distance between two adjacent peaks or two adjacent troughs.

GO FIGURE

If wave (a) has a wavelength of 2.0 m and a frequency of 1.5×10^8 cycles/s, what are the wavelength and frequency of wave (b)?

▲ Figure 6.3 Electromagnetic waves. Like water waves, electromagnetic radiation can be characterized by a wavelength. Notice that the shorter the wavelength, λ , the higher the frequency, ν . The wavelength in (b) is half as long as that in (a), and the frequency of the wave in (b) is therefore twice as great as that in (a).

6.1 | The Wave Nature of Light

Much of our present understanding of the electronic structure of atoms has come from analysis of the light either emitted or absorbed by substances. To understand electronic structure, therefore, we must first learn more about light. The light we see with our eyes, *visible light*, is one type of **electromagnetic radiation**. Because electromagnetic radiation carries energy through space, it is also known as *radiant energy*.

There are many types of electromagnetic radiation in addition to visible light. These different types—radio waves that carry music to our radios, infrared radiation (heat) from a glowing fireplace, X rays—may seem very different from one another, but they all share certain fundamental characteristics.

All types of electromagnetic radiation move through a vacuum at 2.998×10^8 m/s, the *speed of light*. All have wave-like characteristics similar to those of waves that move through water. Water waves are the result of energy imparted to the water, perhaps by the dropping of a stone or the movement of a boat on the water surface (\P Figure 6.1). This energy is expressed as the up-and-down movements of the water.

A cross section of a water wave (Figure 6.2) shows that it is *periodic*, which means that the pattern of peaks and troughs repeats itself at regular intervals. The distance between two adjacent peaks (or between two adjacent troughs) is called the wavelength. The number of complete wavelengths, or *cycles*, that pass a given point each second is the **frequency** of the wave.

Just as with water waves, we can assign a frequency and wavelength to electromagnetic waves, as illustrated in ◀ Figure 6.3. These and all other wave characteristics of electromagnetic radiation are due to the periodic oscillations in the intensities of the electric and magnetic fields associated with the radiation.

The speed of water waves can vary depending on how they are created—for example, the waves produced by a speedboat travel faster than those produced by a rowboat. In contrast, all electromagnetic radiation moves at the same speed, namely, the speed of light. As a result, the wavelength and frequency of electromagnetic radiation are always related in a straightforward way. If the wavelength is long, fewer cycles of the wave pass a given point per second, and so the frequency is low. Conversely, for a wave to have a high frequency, it must have a short wavelength. This inverse relationship between the frequency and wavelength of electromagnetic radiation is expressed by the equation

$$\lambda \nu = c \tag{6.1}$$

where λ (lambda) is wavelength, ν (nu) is frequency, and c is the speed of light.

Why do different types of electromagnetic radiation have different properties? Their differences are due to their different wavelengths. \blacktriangleright Figure 6.4 shows the various types of electromagnetic radiation arranged in order of increasing wavelength, a display called the *electromagnetic spectrum*. Notice that the wavelengths span an enormous range. The wavelengths of gamma rays are comparable to the diameters of atomic nuclei, whereas the wavelengths of radio waves can be longer than a football field. Notice also that visible light, which corresponds to wavelengths of about 400 to 750 nm $(4 \times 10^{-7} \text{ to } 7 \times 10^{-7} \text{ m})$, is an extremely small portion of the electromagnetic spectrum. The unit of length chosen to express wavelength depends on the type of radiation, as shown in \blacktriangleright Table 6.1.

Frequency is expressed in cycles per second, a unit also called a *hertz* (Hz). Because it is understood that cycles are involved, the units of frequency are normally given simply as "per second," which is denoted by s^{-1} or /s. For example, a frequency of 698 megahertz (MHz), a typical frequency for a cellular telephone, could be written as 698 MHz, 698,000,000 Hz, 698,000,000 s^{-1} , or 698,000,000/s.

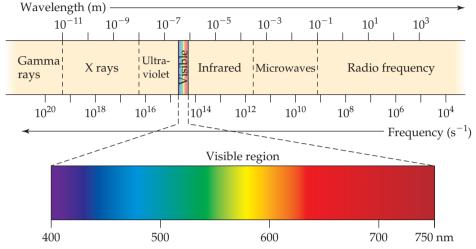

Give It Some Thought

Our bodies are penetrated by X rays but not by visible light. Is this because X rays travel faster than visible light?

GO FIGURE

Is the wavelength of a microwave longer or shorter than the wavelength of visible light? By how many orders of magnitude do the two waves differ in wavelength?

▲ Figure 6.4 The electromagnetic spectrum.* Wavelengths in the spectrum range from very short gamma rays to very long radio waves.

Table 6.1	Common	Wavelength	Units for	Electromagne	etic Radiation
Table 0.1	COLLITION	VV G V CICII E GII	OIII GO TOI	HICCH OIII GEIN	Luc Radiadon

Unit	Symbol	Length (m)	Type of Radiation
Angstrom	Å	10^{-10}	X ray
Nanometer	nm	10^{-9}	Ultraviolet, visible
Micrometer	μ m	10^{-6}	Infrared

Kilometer	km	1000	Radio

SAMPLE EXERCISE 6.1 Concepts of Wavelength and Frequency

Two electromagnetic waves are represented in the margin. (a) Which wave has the higher frequency? (b) If one wave represents visible light and the other represents infrared radiation, which wave is which?

SOLUTION

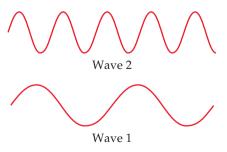

- (a) Wave 1 has a longer wavelength (greater distance between peaks). The longer the wavelength, the lower the frequency ($\nu=c/\lambda$). Thus, Wave 1 has the lower frequency, and Wave 2 has the higher frequency.
- (b) The electromagnetic spectrum (Figure 6.4) indicates that infrared radiation has a longer wavelength than visible light. Thus, Wave 1 would be the infrared radiation.

Practice Exercise 1

A source of electromagnetic radiation produces infrared light. Which of the following could be the wavelength of the light? (a) 3.0 nm (b) 4.7 cm (c) 66.8 m (d) 34.5 μ m (e) 16.5 Å

Practice Exercise 2

If one of the waves in the margin represents blue light and the other red light, which wave is which?

^{*}Based on B.A. Averill and P. Eldredge, *Chemistry: Principles, Patterns, and Applications* 1e, © 2007 Pearson Education, Inc.

SAMPLE EXERCISE 6.2 Calculating Frequency from Wavelength

The yellow light given off by a sodium vapor lamp used for public lighting has a wavelength of 589 nm. What is the frequency of this radiation?

SOLUTION

Analyze We are given the wavelength, λ , of the radiation and asked to calculate its frequency, ν .

Plan The relationship between the wavelength and the frequency is given by Equation 6.1. We can solve for ν and use the values of λ and c to obtain a numerical answer. (The speed of light, c, is 3.00×10^8 m/s to three significant figures.)

Solve Solving Equation 6.1 for frequency gives $\nu = c/\lambda$. When we insert the values for c and λ , we note that the units of length in these two quantities are different. We can convert the wavelength from nanometers to meters, so the units cancel:

$$\nu = \frac{c}{\lambda} = \left(\frac{3.00 \times 10^8 \,\text{m/s}}{589 \,\text{nm}}\right) \left(\frac{1 \,\text{nm}}{10^{-9} \,\text{m}}\right) = 5.09 \times 10^{14} \,\text{s}^{-1}$$

Check The high frequency is reasonable because of the short wavelength. The units are proper because frequency has units of "per second," or s^{-1} .

Practice Exercise 1

Consider the following three statements: (i) For any electromagnetic radiation, the product of the wavelength and the frequency is a constant. (ii) If a source of light has a wavelength of 3.0 Å, its frequency is 1.0×10^{18} Hz. (iii) The speed of ultraviolet light is greater than the speed of microwave radiation. Which of these three statements is or are true? (a) Only one statement is true. (b) Statements (i) and (ii) are true. (c) Statements (i) and (iii) are true. (d) Statements (ii) and (iii) are true.

Practice Exercise 2

(a) A laser used in orthopedic spine surgery produces radiation with a wavelength of 2.10 μm . Calculate the frequency of this radiation. (b) An FM radio station broadcasts electromagnetic radiation at a frequency of 103.4 MHz (megahertz; 1 MHz = $10^6~s^{-1}$). Calculate the wavelength of this radiation. The speed of light is 2.998 \times $10^8~m/s$ to four significant figures.

Which area in the photograph corresponds to the highest temperature?

▲ Figure 6.5 Color and temperature. The color and intensity of the light emitted by a hot object, such as this pour of molten steel, depend on the temperature of the object.

6.2 | Quantized Energy and Photons

Although the wave model of light explains many aspects of the behavior of light, several observations cannot be resolved by this model. Three of these are particularly pertinent to our understanding of how electromagnetic radiation and atoms interact: (1) the emission of light from hot objects (referred to as *blackbody radiation* because the objects studied appear black before heating), (2) the emission of electrons from metal surfaces on which light shines (the *photoelectric effect*), and (3) the emission of light from electronically excited gas atoms (*emission spectra*). We examine the first two phenomena here and the third in Section 6.3.

Hot Objects and the Quantization of Energy

When solids are heated, they emit radiation, as seen in the red glow of an electric stove burner or the bright white light of a tungsten lightbulb. The wavelength distribution of the radiation depends on temperature; a red-hot object, for instance, is cooler than a yellowish or white-hot one (Figure 6.5). During the late 1800s, a number of physicists studied this phenomenon, trying to understand the relationship between the temperature and the intensity and wavelength of the emitted radiation. The prevailing laws of physics could not account for the observations.

In 1900 a German physicist named Max Planck (1858–1947) solved the problem by making a daring assumption: He proposed that energy can be either released or absorbed by atoms only in discrete "chunks" of some minimum size.

Planck gave the name **quantum** (meaning "fixed amount") to the smallest quantity of energy that can be emitted or absorbed as electromagnetic radiation. He proposed that the energy, E, of a single quantum equals a constant times the frequency of the radiation:

$$E = h\nu ag{6.2}$$

The constant h is called **Planck constant** and has a value of 6.626×10^{-34} joule-second (J-s).

According to Planck's theory, matter can emit and absorb energy only in wholenumber multiples of $h\nu$, such as $h\nu$, $2h\nu$, $3h\nu$, and so forth. If the quantity of energy emitted by an atom is $3h\nu$, for example, we say that three quanta of energy have been emitted (*quanta* being the plural of *quantum*). Because the energy can be released only in specific amounts, we say that the allowed energies are *quantized*—their values are restricted to certain quantities. Planck's revolutionary proposal that energy is quantized was proved correct, and he was awarded the 1918 Nobel Prize in Physics for his work on the quantum theory.

If the notion of quantized energies seems strange, it might be helpful to draw an analogy by comparing a ramp and a staircase (**Figure 6.6**). As you walk up a ramp, your potential energy increases in a uniform, continuous manner. When you climb a staircase, you can step only *on* individual stairs, not *between* them, so that your potential energy is restricted to certain values and is therefore quantized.

If Planck's quantum theory is correct, why are its effects not obvious in our daily lives? Why do energy changes seem continuous rather than quantized, or "jagged"? Notice that Planck constant is an extremely small number. Thus, a quantum of energy, $h\nu$, is an extremely small amount. Planck's rules regarding the gain or loss of energy are always the same, whether we are concerned with objects on the scale of our ordinary experience or with microscopic objects. With everyday objects, however, the gain or loss of a single quantum of energy is so small that it goes completely unnoticed. In contrast, when dealing with matter at the atomic level, the impact of quantized energies is far more significant.

Give It Some Thought

Consider the notes that can be played on a piano. In what way is a piano an example of a quantized system? In this analogy, would a violin be continuous or quantized?

Potential energy of person walking up ramp increases in uniform, continuous manner

Potential energy of person walking up steps increases in stepwise, quantized manner

▲ Figure 6.6 Quantized versus continuous change in energy.

The Photoelectric Effect and Photons

A few years after Planck presented his quantum theory, scientists began to see its applicability to many experimental observations. In 1905, Albert Einstein (1879–1955) used Planck's theory to explain the **photoelectric effect** (\triangleright Figure 6.7). Light shining on a clean metal surface causes electrons to be emitted from the surface. A minimum frequency of light, different for different metals, is required for the emission of electrons. For example, light with a frequency of $4.60 \times 10^{14} \, \text{s}^{-1}$ or greater causes cesium metal to emit electrons, but if the light has frequency less than that, no electrons are emitted.

To explain the photoelectric effect, Einstein assumed that the radiant energy striking the metal surface behaves like a stream of tiny energy packets. Each packet, which is like a "particle" of energy, is called a **photon**. Extending Planck's quantum theory, Einstein deduced that each photon must have an energy equal to Planck constant times the frequency of the light:

Energy of photon =
$$E = h\nu$$
 [6.3]

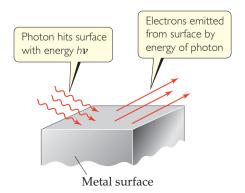

Thus, radiant energy itself is quantized.

Under the right conditions, photons striking a metal surface can transfer their energy to electrons in the metal. A certain amount of energy—called the *work function*—is required for the electrons to overcome the attractive forces holding

GO FIGURE

What is the source of the energy that causes electrons to be emitted from the surface?

▲ Figure 6.7 The photoelectric effect.

them in the metal. If the photons striking the metal have less energy than the work function, the electrons do not acquire sufficient energy to escape from the metal, even if the light beam is intense. If the photons have energy greater than the work function of the particular metal, however, electrons are emitted; any excess energy of the photon is converted into kinetic energy of the emitted electron. The intensity (brightness) of the light is related to the number of photons striking the surface per unit time but not to the energy of each photon. Einstein won the Nobel Prize in Physics in 1921 primarily for his explanation of the photoelectric effect.

Give It Some Thought

In Figure 6.7, will the kinetic energy of an emitted electron equal the energy of the photon that causes its emission?

To better understand what a photon is, imagine you have a light source that produces radiation of a single wavelength. Further suppose that you could switch the light on and off faster and faster to provide ever-smaller bursts of energy. Einstein's photon theory tells us that you would eventually come to the smallest energy burst, given by $E = h\nu$. This smallest burst consists of a single photon of light.

SAMPLE EXERCISE 6.3 Energy of a Photon

Calculate the energy of one photon of yellow light that has a wavelength of 589 nm.

SOLUTION

Analyze Our task is to calculate the energy, *E*, of a photon, given $\lambda = 589$ nm.

Plan We can use Equation 6.1 to convert the wavelength to frequency: $v = c/\lambda$

We can then use Equation 6.3 to calculate energy:

Solve The frequency, ν , is calculated from the given wavelength, as shown in Sample Exercise 6.2:

The value of Planck constant, h, is given both in the text and in the table of physical constants on the inside back cover of the text, and so we can easily calculate E:

Comment If one photon of radiant energy supplies 3.37×10^{-19} J, we calculate that one mole of these photons will supply:

 $\nu = c/\lambda = 5.09 \times 10^{14} \,\mathrm{s}^{-1}$

 $E = h\nu$

 $E = (6.626 \times 10^{-34} \text{ J-s})(5.09 \times 10^{14} \text{ s}^{-1}) = 3.37 \times 10^{-19} \text{ J}$

 $(6.02 \times 10^{23} \text{ photons/mol})(3.37 \times 10^{-19} \text{ J/photon})$

 $= 2.03 \times 10^5 \text{ J/mol}$

Practice Exercise 1

Which of the following expressions correctly gives the energy of a mole of photons with wavelength λ ?

(a)
$$E = \frac{h}{\lambda}$$
 (b) $E = N_A \frac{\lambda}{h}$ (c) $E = \frac{hc}{\lambda}$ (d) $E = N_A \frac{h}{\lambda}$ (e) $E = N_A \frac{hc}{\lambda}$

Practice Exercise 2

(a) A laser emits light that has a frequency of $4.69 \times 10^{14} \, \mathrm{s^{-1}}$. What is the energy of one photon of this radiation? (b) If the laser emits a pulse containing 5.0×10^{17} photons of this radiation, what is the total energy of that pulse? (c) If the laser emits $1.3 \times 10^{-2} \, \mathrm{J}$ of energy during a pulse, how many photons are emitted?

The idea that the energy of light depends on its frequency helps us understand the diverse effects that different kinds of electromagnetic radiation have on matter. For example, because of the high frequency (short wavelength) of X rays (Figure 6.4), X-ray photons cause tissue damage and even cancer. Thus, signs are normally posted around X-ray equipment warning us of high-energy radiation.

Although Einstein's theory of light as a stream of photons rather than a wave explains the photoelectric effect and a great many other observations, it also poses a dilemma. Is light a wave, or does it consist of particles? The only way to resolve this dilemma is to adopt what might seem to be a bizarre position: We must consider that light possesses both wave-like and particle-like characteristics and, depending on the situation, will behave more like waves or more like particles. We will soon see that this dual wave-particle nature is also a characteristic trait of matter.

Give It Some Thought

Do you think that the formation of a rainbow is more a demonstration of the wave-like or particle-like behavior of light?

6.3 | Line Spectra and the Bohr Model

The work of Planck and Einstein paved the way for understanding how electrons are arranged in atoms. In 1913, the Danish physicist Niels Bohr (▶ Figure 6.8) offered a theoretical explanation of *line spectra*, another phenomenon that had puzzled scientists during the nineteenth century. We will see that Bohr used the ideas of Planck and Einstein to explain the line spectrum of hydrogen.

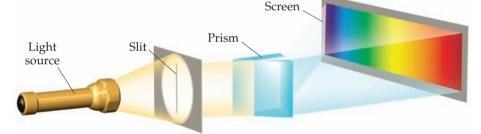

▲ Figure 6.8 Quantum giants. Niels Bohr (right) with Albert Einstein. Bohr (1885–1962) made major contributions to the quantum theory and was awarded the Nobel Prize in Physics in 1922.

Line Spectra

A particular source of radiant energy may emit a single wavelength, as in the light from a laser. Radiation composed of a single wavelength is *monochromatic*. However, most common radiation sources, including lightbulbs and stars, produce radiation containing many different wavelengths and is *polychromatic*. A **spectrum** is produced when radiation from such sources is separated into its component wavelengths,

as shown in A Figure 6.9. The resulting spectrum consists of a continuous range of colors—violet merges into indigo, indigo into blue, and so forth, with no (or very few) blank spots. This rainbow of colors, containing light of all wavelengths, is called a continuous spectrum. The most familiar example of a continuous spectrum is the rainbow produced when raindrops or mist acts as a prism for sunlight.

Not all radiation sources produce a continuous spectrum. When a high voltage is applied to tubes that contain different gases under reduced pressure, the gases emit different colors of light (> Figure 6.10). The light emitted by neon gas is the familiar red-orange glow of many "neon" lights, whereas sodium vapor emits the yellow light characteristic of some modern streetlights. When light coming from such tubes is passed through a prism, only a few wavelengths are present in the resultant spectra (Figure 6.11). Each colored line in such spectra represents light of one wavelength. A spectrum containing radiation of only specific wavelengths is called a line spectrum.

▲ Figure 6.9 Creating a spectrum. A continuous visible spectrum is produced when a narrow beam of white light is passed through a prism. The white light could be sunlight or light from an incandescent lamp.

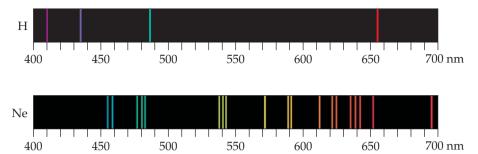

Neon (Ne)

Hydrogen (H)

▲ Figure 6.10 Atomic emission of hydrogen and neon. Different gases emit light of different characteristic colors when an electric current is passed through them.

▲ Figure 6.11 Line spectra of hydrogen and neon. The colored lines occur at wavelengths present in the emission. The black regions are wavelengths for which no light is produced in the emission.

When scientists first detected the line spectrum of hydrogen in the mid-1800s, they were fascinated by its simplicity. At that time, only four lines at wavelengths of 410 nm (violet), 434 nm (blue), 486 nm (blue-green), and 656 nm (red) were observed (Figure 6.11). In 1885, a Swiss schoolteacher named Johann Balmer showed that the wavelengths of these four lines fit an intriguingly simple formula that relates the wavelengths to integers. Later, additional lines were found in the ultraviolet and infrared regions of hydrogen's line spectrum. Soon Balmer's equation was extended to a more general one, called the *Rydberg equation*, which allows us to calculate the wavelengths of all the spectral lines of hydrogen:

$$\frac{1}{\lambda} = (R_{\rm H}) \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right)$$
 [6.4]

In this formula λ is the wavelength of a spectral line, $R_{\rm H}$ is the *Rydberg constant* (1.096776 \times 10⁷ m⁻¹), and n_1 and n_2 are positive integers, with n_2 being larger than n_1 . How could the remarkable simplicity of this equation be explained? It took nearly 30 more years to answer this question.

Bohr's Model

Rutherford's discovery of the nuclear atom (Section 2.2) suggested that an atom might be thought of as a "microscopic solar system" in which the electrons orbit the nucleus. To explain the line spectrum of hydrogen, Bohr assumed that electrons in hydrogen atoms move in circular orbits around the nucleus, but this assumption posed a problem. According to classical physics, a charged particle (such as an electron) moving in a circular path should continuously lose energy. As an electron loses energy, therefore, it should spiral into the positively charged nucleus. This behavior, however, does not happen—hydrogen atoms are stable. So how can we explain this apparent violation of the laws of physics? Bohr approached this problem in much the same way that Planck had approached the problem of the nature of the radiation emitted by hot objects: He assumed that the prevailing laws of physics were inadequate to describe all aspects of atoms. Furthermore, he adopted Planck's idea that energies are quantized.

Bohr based his model on three postulates:

- 1. Only orbits of certain radii, corresponding to certain specific energies, are permitted for the electron in a hydrogen atom.
- 2. An electron in a permitted orbit is in an "allowed" energy state. An electron in an allowed energy state does not radiate energy and, therefore, does not spiral into the nucleus.
- **3.** Energy is emitted or absorbed by the electron only as the electron changes from one allowed energy state to another. This energy is emitted or absorbed as a photon that has energy $E = h\nu$.

Give It Some Thought

With reference to Figure 6.6, in what way is the Bohr model for the H atom more like steps than a ramp?

The Energy States of the Hydrogen Atom

Starting with his three postulates and using classical equations for motion and for interacting electrical charges, Bohr calculated the energies corresponding to the allowed orbits for the electron in the hydrogen atom. Ultimately, the calculated energies fit the formula

$$E = (-hcR_{\rm H}) \left(\frac{1}{n^2}\right) = (-2.18 \times 10^{-18} \,\text{J}) \left(\frac{1}{n^2}\right)$$
 [6.5]

where h, c, and $R_{\rm H}$ are Planck constant, the speed of light, and the Rydberg constant, respectively. The integer n, which can have whole-number values of 1, 2, 3, ... ∞ , is called the **principal quantum number**.

Each allowed orbit corresponds to a different value of n. The radius of the orbit gets larger as n increases. Thus, the first allowed orbit (the one closest to the nucleus) has n = 1, the next allowed orbit (the one second closest to the nucleus) has n = 2, and so forth. The electron in the hydrogen atom can be in any allowed orbit, and Equation 6.5 tells us the energy the electron has in each allowed orbit.

Note that the energies of the electron given by Equation 6.5 are negative for all values of n. The lower (more negative) the energy is, the more stable the atom is. The energy is lowest (most negative) for n=1. As n gets larger, the energy becomes less negative and therefore increases. We can liken the situation to a ladder in which the rungs are numbered from the bottom. The higher one climbs (the greater the value of n), the higher the energy. The lowest-energy state (n=1, analogous to the bottom rung) is called the **ground state** of the atom. When the electron is in a higher-energy state (n=2 or higher), the atom is said to be in an **excited state**. \triangleright **Figure 6.12** shows the allowed energy levels for the hydrogen atom for several values of n.

Give It Some Thought

Why does it make sense that an orbit with a larger radius has a higher energy than one with a smaller radius?

What happens to the orbit radius and the energy as n becomes infinitely large? The radius increases as n^2 , so when $n = \infty$ the electron is completely separated from the nucleus, and the energy of the electron is zero:

$$E = (-2.18 \times 10^{-18} \,\mathrm{J}) \left(\frac{1}{\infty^2}\right) = 0$$

The state in which the electron is completely separated from the nucleus is called the *reference*, or zero-energy, state of the hydrogen atom.

In his third postulate, Bohr assumed that the electron can "jump" from one allowed orbit to another by either absorbing or emitting photons whose radiant energy corresponds exactly to the energy difference between the two orbits. The electron must absorb energy in order to move to a higher-energy state (higher value of n). Conversely, radiant energy is emitted when the electron jumps to a lower-energy state (lower value of n).

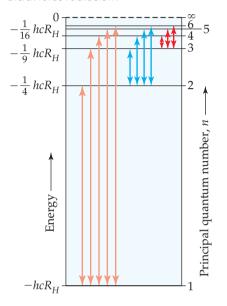

Let's consider a case in which the electron jumps from an initial state with principal quantum number n_i and energy E_i to a final state with principal quantum number n_f and energy E_f . Using Equation 6.5, we see that the change in energy for this transition is

$$\Delta E = E_{\rm f} - E_{\rm i} = (-2.18 \times 10^{-18} \,\text{J}) \left(\frac{1}{n_{\rm f}^2} - \frac{1}{n_{\rm i}^2}\right)$$
 [6.6]

What is the significance of the *sign* of ΔE ? Notice that ΔE is positive when $n_{\rm f}$ is greater than $n_{\rm i}$. That makes sense to us because that means the electron is jumping to a higher-energy orbit. Conversely, ΔE is negative when $n_{\rm f}$ is less than $n_{\rm i}$; the electron is falling in energy to a lower-energy orbit.

GO FIGURE

If the transition of an electron from the n=3 state to the n=2 state results in emission of visible light, is the transition from the n=2 state to the n=1 state more likely to result in the emission of infrared or ultraviolet radiation?

A Figure 6.12 Energy levels in the hydrogen atom from the Bohr model. The arrows refer to the transitions of the electron from one allowed energy state to another. The states shown are those for which n = 1 through n = 6 and the state for $n = \infty$ for which the energy, E, equals zero.

As noted above, transitions from one allowed state to another will involve a photon. The energy of the photon $(E_{\rm photon})$ must equal the difference in energy between the two states (ΔE) . When ΔE is positive, a photon must be absorbed as the electron jumps to a higher energy. When ΔE is negative, a photon is emitted as the electron falls to a lower energy level. In both cases, the energy of the photon must match the energy difference between the states. Because the frequency ν is always a positive number, the energy of the photon $(h\nu)$ must always be positive. Thus, the sign of ΔE tells us whether the photon is absorbed or emitted:

$$\Delta E > 0 \ (n_{\rm f} > n_{\rm i})$$
: Photon absorbed with $E_{\rm photon} = h\nu = \Delta E$
 $\Delta E < 0 \ (n_{\rm f} < n_{\rm i})$: Photon emitted with $E_{\rm photon} = h\nu = -\Delta E$ [6.7]

These two situations are summarized in ▼ Figure 6.13. We see that Bohr's model of the hydrogen atom leads to the conclusion that only the specific frequencies of light that satisfy Equation 6.7 can be absorbed or emitted by the atom.

Let's see how to apply these concepts by considering a transition in which the electron moves from $n_i = 3$ to $n_f = 1$. From Equation 6.6 we have

$$\Delta E = (-2.18 \times 10^{-18} \,\mathrm{J}) \left(\frac{1}{1^2} - \frac{1}{3^2}\right) = (-2.18 \times 10^{-18} \,\mathrm{J}) \left(\frac{8}{9}\right) = -1.94 \times 10^{-18} \,\mathrm{J}$$

The value of ΔE is negative—that makes sense because the electron is falling from a higher-energy orbit (n=3) to a lower-energy orbit (n=1). A photon is *emitted* during this transition, and the energy of the photon is equal to $E_{\rm photon} = h\nu = -\Delta E = +1.94 \times 10^{-18} \, \rm J.$

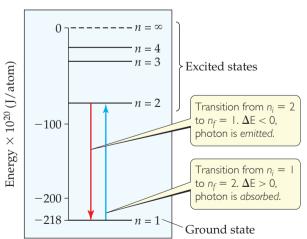

Knowing the energy of the emitted photon, we can calculate either its frequency or its wavelength. For the wavelength, we recall that $\lambda = c/\nu = hc/E_{\rm photon}$ and obtain

$$\lambda = \frac{c}{\nu} = \frac{hc}{E_{\text{photon}}} = \frac{hc}{-\Delta E} = \frac{(6.626 \times 10^{-34} \,\text{J-s})(2.998 \times 10^8 \,\text{m/s})}{+1.94 \times 10^{-18} \,\text{J}} = 1.02 \times 10^{-7} \,\text{m}$$

Thus, a photon of wavelength 1.02 \times 10⁻⁷ m (102 nm) is *emitted*.

Which transition will lead to the emission of light with longer wavelength, n = 3 to n = 2, or n = 4 to n = 3?

▲ Figure 6.13 Change in energy states for absorption and emission.

Give It Some Thought

What is the significance of the minus sign in front of ΔE in the above equation?

We are now in a position to understand the remarkable simplicity of the line spectra of hydrogen, first discovered by Balmer. We recognize that the line spectra are the result of emission, so $E_{\rm photon}=h\nu=hc/\lambda=-\Delta E$ for these transitions. Combining Equations 6.5 and 6.6 we see that

$$E_{\rm photon} = \frac{hc}{\lambda} = -\Delta E = hcR_{\rm H} \left(\frac{1}{n_e^2} - \frac{1}{n_i^2}\right)$$
 (for emission)

which gives us

$$\frac{1}{\lambda} = \frac{hcR_{\rm H}}{hc} \left(\frac{1}{n_{\rm f}^2} - \frac{1}{n_{\rm i}^2}\right) = R_{\rm H} \left(\frac{1}{n_{\rm f}^2} - \frac{1}{n_{\rm i}^2}\right), \text{ where } n_{\rm f} < n_{\rm i}$$

Thus, the existence of discrete spectral lines can be attributed to the quantized jumps of electrons between energy levels.

Give It Some Thought

What is the relationship between $1/\lambda$ and ΔE for a transition of the electron from a lower value of n to a higher one?

SAMPLE EXERCISE 6.4 Electronic Transitions in the Hydrogen Atom

Using Figure 6.12, predict which of these electronic transitions produces the spectral line having the longest wavelength: n = 2 to n = 1, n = 3 to n = 2, or n = 4 to n = 3.

SOLUTION

The wavelength increases as frequency decreases ($\lambda=c/\nu$). Hence, the longest wavelength will be associated with the lowest frequency. According to Planck's equation, $E=h\nu$, the lowest frequency is associated with the lowest energy. In Figure 6.12 the shortest vertical line represents the smallest energy change. Thus, the n=4 to n=3 transition produces the longest wavelength (lowest frequency) line.

Practice Exercise 1

In the top part of Figure 6.11, the four lines in the H atom spectrum are due to transitions from a level for which $n_i > 2$ to the $n_f = 2$ level. What is the value of n_i for the blue-green line in the spectrum? (a) 3 (b) 4 (c) 5 (d) 6 (e) 7

Practice Exercise 2

For each of the following transitions, give the sign of ΔE and indicate whether a photon is emitted or absorbed: (a) n = 3 to n = 1; (b) n = 2 to n = 4.

Limitations of the Bohr Model

Although the Bohr model explains the line spectrum of the hydrogen atom, it cannot explain the spectra of other atoms, except in a crude way. Bohr also avoided the problem of why the negatively charged electron would not just fall into the positively charged nucleus, by simply assuming it would not happen. Furthermore, there is a problem with describing an electron merely as a small particle circling the nucleus. As we will see in Section 6.4, the electron exhibits wave-like properties, a fact that any acceptable model of electronic structure must accommodate.

As it turns out, the Bohr model was only an important step along the way toward the development of a more comprehensive model. What is most significant about Bohr's model is that it introduces two important ideas that are also incorporated into our current model:

- 1. Electrons exist only in certain discrete energy levels, which are described by quantum numbers.
- **2.** *Energy is involved in the transition of an electron from one level to another.*

We will now start to develop the successor to the Bohr model, which requires that we take a closer look at the behavior of matter.

6.4 | The Wave Behavior of Matter

In the years following the development of Bohr's model for the hydrogen atom, the dual nature of radiant energy became a familiar concept. Depending on the experimental circumstances, radiation appears to have either a wave-like or a particle-like (photon) character. Louis de Broglie (1892–1987), who was working on his Ph.D. thesis in physics at the Sorbonne in Paris, boldly extended this idea: If radiant energy could, under appropriate conditions, behave as though it were a stream of particles (photons), could matter, under appropriate conditions, possibly show the properties of a wave?

De Broglie suggested that an electron moving about the nucleus of an atom behaves like a wave and therefore has a wavelength. He proposed that the wavelength of the electron, or of any other particle, depends on its mass, *m*, and on its velocity, *v*:

$$\lambda = \frac{h}{mv} \tag{6.8}$$

where h is Planck constant. The quantity mv for any object is called its **momentum**. De Broglie used the term matter waves to describe the wave characteristics of material particles.

Because de Broglie's hypothesis is applicable to all matter, any object of mass m and velocity v would give rise to a characteristic matter wave. However, Equation 6.8 indicates that the wavelength associated with an object of ordinary size, such as a golf ball, is so tiny as to be completely unobservable. This is not so for an electron because its mass is so small, as we see in Sample Exercise 6.5.

SAMPLE **EXERCISE 6.5** Matter Waves

What is the wavelength of an electron moving with a speed of 5.97 \times 10⁶ m/s? The mass of the electron is 9.11×10^{-31} kg.

SOLUTION

Analyze We are given the mass, m, and velocity, v, of the electron, and we must calculate its de Broglie wavelength, λ .

Plan The wavelength of a moving particle is given by Equation 6.8, so λ is calculated by inserting the known quantities h, m, and ν . In doing so, however, we must pay attention to units.

Solve Using the value of Planck constant:

$$h = 6.626 \times 10^{-34} \,\text{J-s}$$

we have the following:

$$\lambda = \frac{h}{mv}$$

$$= \frac{(6.626 \times 10^{-34} \,\text{J-s})}{(9.11 \times 10^{-31} \,\text{kg})(5.97 \times 10^6 \,\text{m/s})} \left(\frac{1 \,\text{kg-m}^2/\text{s}^2}{1 \,\text{J}}\right)$$

$$= 1.22 \times 10^{-10} \,\text{m} = 0.122 \,\text{nm} = 1.22 \,\text{Å}$$

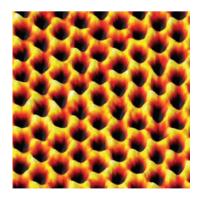

Comment By comparing this value with the wavelengths of electromagnetic radiation shown in Figure 6.4, we see that the wavelength of this electron is about the same as that of X rays.

Practice Exercise 1

Consider the following three moving objects: (i) a golf ball with a mass of 45.9 g moving at a speed of 50.0 m/s, (ii) An electron moving at a speed of $3.50 \times 10^5 \text{ m/s}$, (iii) A neutron moving at a speed of 2.3×10^2 m/s. List the three objects in order from shortest to longest de Broglie wavelength. (a) i < iii < ii (b) ii < iii < i (c) iii < ii < i (d) i < ii < iii (e) iii < i < ii

Practice Exercise 2

Calculate the velocity of a neutron whose de Broglie wavelength is 505 pm. The mass of a neutron is given in the table inside the back cover of the text.

▲ Figure 6.14 Electrons as waves. Transmission electron micrograph of

graphene, which has a hexagonal honeycomb arrangement of carbon atoms. Each of the bright yellow "mountains" indicates a carbon atom.

A few years after de Broglie published his theory, the wave properties of the electron were demonstrated experimentally. When X rays pass through a crystal, an interference pattern results that is characteristic of the wave-like properties of electromagnetic radiation, a phenomenon called X-ray diffraction. As electrons pass through a crystal, they are similarly diffracted. Thus, a stream of moving electrons exhibits the same kinds of wave behavior as X rays and all other types of electromagnetic radiation.

The technique of electron diffraction has been highly developed. In the electron microscope, for instance, the wave characteristics of electrons are used to obtain images at the atomic scale. This microscope is an important tool for studying surface phenomena at very high magnifications (◀ Figure 6.14). Electron microscopes can magnify objects by 3,000,000 times, far more than can be done with visible light ($1000\times$), because the wavelength of the electrons is so much smaller than the wavelength of visible light.

Give It Some Thought

A baseball pitcher throws a fastball that moves at 95 miles per hour. Does that moving baseball generate matter waves? If so, can we observe them?

The Uncertainty Principle

The discovery of the wave properties of matter raised some new and interesting questions. Consider, for example, a ball rolling down a ramp. Using the equations of classical physics, we can calculate, with great accuracy, the ball's position, direction of motion, and speed at any instant. Can we do the same for an electron, which exhibits wave properties? A wave extends in space and its location is not precisely defined. We might therefore anticipate that it is impossible to determine exactly where an electron is located at a specific instant.

The German physicist Werner Heisenberg (Figure 6.15) proposed that the dual nature of matter places a fundamental limitation on how precisely we can know both the location and the momentum of an object at a given instant. The limitation becomes important only when we deal with matter at the subatomic level (that is, with masses as small as that of an electron). Heisenberg's principle is called the **uncertainty principle**. When applied to the electrons in an atom, this principle states that it is impossible for us to know simultaneously both the exact momentum of the electron and its exact location in space.

Heisenberg mathematically related the uncertainty in position, Δx , and the uncertainty in momentum, $\Delta(mv)$, to a quantity involving Planck constant:

$$\Delta x \cdot \Delta(mv) \ge \frac{h}{4\pi} \tag{6.9}$$

A brief calculation illustrates the dramatic implications of the uncertainty principle. The electron has a mass of $9.11\times 10^{-31}\,\mathrm{kg}$ and moves at an average speed of about $5\times 10^6\,\mathrm{m/s}$ in a hydrogen atom. Let's assume that we know the speed to an uncertainty of 1% [that is, an uncertainty of $(0.01)(5\times 10^6\,\mathrm{m/s})=5\times 10^4\,\mathrm{m/s}]$ and that this is the only important source of uncertainty in the momentum, so that $\Delta(mv)=m\,\Delta v$. We can use Equation 6.9 to calculate the uncertainty in the position of the electron:

$$\Delta x \ge \frac{h}{4\pi m \Delta v} = \left(\frac{6.626 \times 10^{-34} \,\text{J-s}}{4\pi (9.11 \times 10^{-31} \,\text{kg})(5 \times 10^4 \,\text{m/s})}\right) = 1 \times 10^{-9} \,\text{m}$$

Because the diameter of a hydrogen atom is about 1×10^{-10} m, the uncertainty in the position of the electron in the atom is an order of magnitude greater than the size of the atom. Thus, we have essentially no idea where the electron is located in the atom. On the other hand, if we were to repeat the calculation with an object of ordinary mass, such as a tennis ball, the uncertainty would be so small that it would be inconsequential. In that case, m is large and Δx is out of the realm of measurement and therefore of no practical consequence.

De Broglie's hypothesis and Heisenberg's uncertainty principle set the stage for a new and more broadly applicable theory of atomic structure. In this approach, any attempt to define precisely the instantaneous location and momentum of the electron is abandoned. The wave nature of the electron is recognized, and its behavior is described in terms appropriate to waves. The result is a model that precisely describes the energy of the electron while describing its location not precisely but rather in terms of probabilities.

▲ Figure 6.15 Werner Heisenberg (1901–1976). During his postdoctoral assistantship with Niels Bohr, Heisenberg formulated his famous uncertainty principle. At 32 he was one of the youngest scientists to receive a Nobel Prize.

A Closer Look

Measurement and the Uncertainty Principle

Whenever any measurement is made, some uncertainty exists. Our experience with objects of ordinary dimensions, such as balls or trains or laboratory equipment, indicates that using more precise instruments can decrease the uncertainty of a measurement. In fact, we might expect that the uncertainty in a measurement can be made indefinitely small. However, the uncertainty principle states that there is an actual limit to the accuracy of measurements. This limit is not a restriction on how well instruments can be made; rather, it is inherent

in nature. This limit has no practical consequences when dealing with ordinary-sized objects, but its implications are enormous when dealing with subatomic particles, such as electrons.

To measure an object, we must disturb it, at least a little, with our measuring device. Imagine using a flashlight to locate a large rubber ball in a dark room. You see the ball when the light from the flashlight bounces off the ball and strikes your eyes. When a beam of photons strikes an object of this size, it does not alter its position or momentum to any practical extent. Imagine, however, that you wish to locate an electron by similarly bouncing light off it into some detector. Objects can be located

to an accuracy no greater than the wavelength of the radiation used. Thus, if we want an accurate position measurement for an electron, we must use a short wavelength. This means that photons of high energy must be employed. The more energy the photons have, the more momentum they impart to the electron when they strike it, which changes the electron's motion in an unpredictable way. The attempt to measure accurately the electron's position introduces considerable uncertainty in its momentum; the act of measuring the electron's position at one moment makes our knowledge of its future position inaccurate.

Suppose, then, that we use photons of longer wavelength. Because these photons have lower energy, the momentum of the electron is not so appreciably changed during measurement, but its position will be correspondingly less accurately known. This is the essence of the uncertainty principle: *There is an uncertainty in simultaneously knowing both the position and the momentum of the electron that cannot be reduced beyond a certain minimum level*. The more accurately one is known, the less accurately the other is known.

Although we can never know the exact position and momentum of the electron, we can talk about the probability of its being at certain locations in space. In Section 6.5 we introduce a model of the atom that provides the probability of finding electrons of specific energies at certain positions in atoms.

Give It Some Thought

What is the principal reason we must consider the uncertainty principle when discussing electrons and other subatomic particles but not when discussing our macroscopic world?

6.5 | Quantum Mechanics and Atomic Orbitals

In 1926 the Austrian physicist Erwin Schrödinger (1887–1961) proposed an equation, now known as *Schrödinger's wave equation*, that incorporates both the wave-like and particle-like behaviors of the electron. His work opened a new approach to dealing with subatomic particles, an approach known as *quantum mechanics* or *wave mechanics*. The application of Schrödinger's equation requires advanced calculus, and so we will not be concerned with its details. We will, however, qualitatively consider the results Schrödinger obtained because they give us a powerful new way to view electronic structure. Let's begin by examining the electronic structure of the simplest atom, hydrogen.

Schrödinger treated the electron in a hydrogen atom like the wave on a plucked guitar string (▼ Figure 6.16). Because such waves do not travel in space, they are called

▲ Figure 6.16 Standing waves in a vibrating string.

standing waves. Just as the plucked guitar string produces a standing wave that has a fundamental frequency and higher overtones (harmonics), the electron exhibits a lowest-energy standing wave and higher-energy ones. Furthermore, just as the overtones of the guitar string have *nodes*, points where the magnitude of the wave is zero, so do the waves characteristic of the electron.

Solving Schrödinger's equation for the hydrogen atom leads to a series of mathematical functions called **wave functions** that describe the electron in the atom. These wave functions are usually represented by the symbol ψ (lowercase Greek letter psi). Although the wave function has no direct physical meaning, the square of the wave function, ψ^2 , provides information about the electron's location when it is in an allowed energy state.

For the hydrogen atom, the allowed energies are the same as those predicted by the Bohr model. However, the Bohr model assumes that the electron is in a circular orbit of some particular radius about the nucleus. In the quantum mechanical model, the electron's location cannot be described so simply.

According to the uncertainty principle, if we know the momentum of the electron with high accuracy, our simultaneous knowledge of its location is very uncertain. Thus, we cannot hope to specify the exact location of an individual electron around the nucleus. Rather, we must be content with a kind of statistical knowledge. We therefore speak of the *probability* that the electron will be in a certain region of space at a given instant. As it turns out, the square of the wave function, ψ^2 , at a given point in space represents the probability that the electron will be found at that location. For this reason, ψ^2 is called either the **probability density** or the **electron density**.

Give It Some Thought

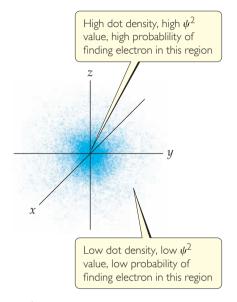

What is the difference between stating "The electron is located at a particular point in space" and "There is a high probability that the electron is located at a particular point in space"?

One way of representing the probability of finding the electron in various regions of an atom is shown in \blacktriangleright Figure 6.17, where the density of the dots represents the probability of finding the electron. The regions with a high density of dots correspond to relatively large values for ψ^2 and are therefore regions where there is a high probability of finding the electron. Based on this representation, we often describe atoms as consisting of a nucleus surrounded by an electron cloud.

GO FIGURE

Where in the figure is the region of highest electron density?

▲ Figure 6.17 Electron-density distribution. This rendering represents the probability, ψ^2 , of finding the electron in a hydrogen atom in its ground state. The origin of the coordinate system is at the nucleus.

A Closer Look

Thought Experiments and Schrödinger's Cat

The revolutions in scientific thinking caused by the theory of relativity and quantum theory not only changed science; it also caused deep changes in how we understand the world around us. Before relativity and quantum theory, the prevailing physical theories were inherently *deterministic*: Once the specific conditions of an object were given (position, velocity, forces acting on the object), we could determine exactly the position and motion of the object at any time in the future. These theories, from Newton's laws to Maxwell's theory of electromagnetism, successfully described physical phenomena such as motion of the planets, the trajectories of projectiles, and the diffraction of light.

Relativity and quantum theory both challenged the deterministic view of the universe, and did so in a way that caused a great deal of uneasiness among even the scientists who were developing the theories. One of the common methods scientists used to test these new theories was through so-called "thought experiments." Thought experiments are hypothetical scenarios that can lead to paradoxes within a given theory. Let's briefly discuss one of these thought experiments that was used to test ideas within quantum theory.

The quantum theory caused a great deal of discussion with respect to its nondeterministic description of matter. We have touched on two such areas in this chapter. First, we have seen that the descriptions of light and matter have become less distinct—light has particle-like properties and matter has wave-like properties. The description of matter that results—in which we can talk only about the probability of an electron being at a certain place as opposed to knowing exactly where it is—was very bothersome to many. Einstein, for example, famously said that "God doesn't play dice with the world"* about this probabilistic description. Heisenberg's uncertainty principle, which assures that we can't know the position and momentum of a particle exactly, also raised many philosophical questions—so many, in fact, that Heisenberg wrote a book entitled *Physics and Philosophy* in 1958.

One of the most famous thought experiments put forward in the early days of the quantum theory was formulated by Schrödinger and is now known as "Schrödinger's cat." This experiment called into question whether a system could have multiple acceptable wave functions prior to observation of the system. In other words, if we don't actually observe a system, can we know anything about the state it is in?

^{*}Hermanns, William, Einstein and the Poet: In Search of the Cosmic Man, 1st edition, Branden Books, 1983.

In this paradox, a hypothetical cat is placed in a sealed box with an apparatus that will randomly trigger a lethal dose of poison to the cat (as morbid as that sounds). According to some interpretations of quantum theory, until the box is opened and the cat is observed, the cat must be considered simultaneously alive and dead.

Schrödinger posed this paradox to point out weaknesses in some interpretations of quantum results, but the paradox has led instead to a continuing and lively debate about the fate and meaning of Schrödinger's cat. In 2012, the Nobel Prize in physics was awarded to Serge Haroche of France and David Wineland of the United States

for their ingenious methods for observing the quantum states of photons or particles without having the act of observation destroy the states. In so doing, they observed what is generally called the "cat state" of the systems, in which the photon or particle exists simultaneously in two different quantum states. A puzzling paradox, indeed, but that one might ultimately lead to new ways to harness the simultaneous states to create so-called quantum computers and more accurate clocks.

Orbitals and Quantum Numbers

The solution to Schrödinger's equation for the hydrogen atom yields a set of wave functions called **orbitals**. Each orbital has a characteristic shape and energy. For example, the lowest-energy orbital in the hydrogen atom has the spherical shape illustrated in Figure 6.17 and an energy of -2.18×10^{-18} J. Note that an *orbital* (quantum mechanical model, which describes electrons in terms of probabilities, visualized as "electron clouds") is not the same as an *orbit* (the Bohr model, which visualizes the electron moving in a physical orbit, like a planet around a star). The quantum mechanical model does not refer to orbits because the motion of the electron in an atom cannot be precisely determined (Heisenberg's uncertainty principle).

The Bohr model introduced a single quantum number, n, to describe an orbit. The quantum mechanical model uses three quantum numbers, n, l, and m_l , which result naturally from the mathematics used to describe an orbital.

- 1. The principal quantum number, n, can have positive integral values $1, 2, 3, \ldots$. As n increases, the orbital becomes larger, and the electron spends more time farther from the nucleus. An increase in n also means that the electron has a higher energy and is therefore less tightly bound to the nucleus. For the hydrogen atom, $E_n = -(2.18 \times 10^{-18} \, \text{J})(1/n^2)$, as in the Bohr model.
- **2.** The second quantum number—the **angular momentum quantum number**, l—can have integral values from 0 to (n-1) for each value of n. This quantum number defines the shape of the orbital. The value of l for a particular orbital is generally designated by the letters s, p, d, and f,* corresponding to l values of 0, 1, 2, and 3:

Value of l	0	1	2	3
Letter used	S	р	d	f

3. The **magnetic quantum number**, m_l , can have integral values between -l and l, including zero. This quantum number describes the orientation of the orbital in space, as we discuss in Section 6.6.

Notice that because the value of n can be any positive integer, there is an infinite number of orbitals for the hydrogen atom. At any given instant, however, the electron in a hydrogen atom is described by only one of these orbitals—we say that the electron *occupies* a certain orbital. The remaining orbitals are *unoccupied* for that particular state of the hydrogen atom. We will focus mainly on orbitals that have small values of n.

Give It Some Thought

What is the difference between an *orbit* in the Bohr model of the hydrogen atom and an *orbital* in the quantum mechanical model?

^{*}The letters come from the words *sharp*, *principal*, *diffuse*, and *fundamental*, which were used to describe certain features of spectra before quantum mechanics was developed.

Table 6.2 Relationship among Values of n , l , and m_l through $n=4$	Table 6.2	Relationship	among Values	s of n. l	and m	through $n = 4$	
--	-----------	--------------	--------------	-----------	-------	-----------------	--

n	Possible Values of l	Subshell Designation	Possible Values of m _l	Number of Orbitals in Subshell	Total Number of Orbitals in Shell
1	0	1s	0	1	1
2	0	2 <i>s</i>	0	1	
	1	2 <i>p</i>	1, 0, -1	3	4
3	0	3 <i>s</i>	0	1	
	1	3 <i>p</i>	1, 0, -1	3	
	2	3 <i>d</i>	2, 1, 0, -1, -2	5	9
4	0	4s	0	1	
	1	4p	1, 0, -1	3	
	2	4d	2, 1, 0, -1, -2	5	
	3	4f	3, 2, 1, 0, -1, -2, -3	7	16

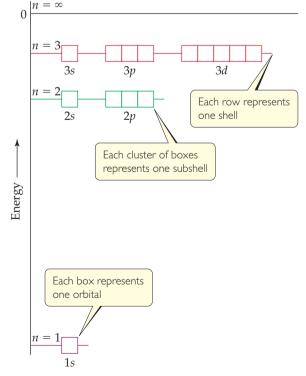

The collection of orbitals with the same value of n is called an **electron shell**. All the orbitals that have n = 3, for example, are said to be in the third shell. The set of orbitals that have the same n and l values is called a **subshell**. Each subshell is designated by a number (the value of n) and a letter (s, p, d, or f, corresponding to the value of l). For example, the orbitals that have n = 3 and l = 2 are called 3d orbitals and are in the 3d subshell.

▲ Table 6.2 summarizes the possible values of l and m_l for values of n through n = 4. The restrictions on possible values give rise to the following very important observations:

- 1. The shell with principal quantum number n consists of exactly n subshells. Each subshell corresponds to a different allowed value of l from 0 to (n-1). Thus, the first shell (n=1) consists of only one subshell, the ls(l=0); the second shell (n=2) consists of two subshells, the ls(l=0) and ls(l=1); the third shell consists of three subshells, ls(l=0) and ls(l=1); the third shell consists of three subshells, ls(l=0) and ls(l=1); the third shell consists of three subshells, ls(l=1); and ls(l=1); ls(l=1);
- **2.** Each subshell consists of a specific number of orbitals. Each orbital corresponds to a different allowed value of m_l . For a given value of l, there are (2l+1) allowed values of m_b ranging from -l to +l. Thus, each s(l=0) subshell consists of one orbital; each p(l=1) subshell consists of three orbitals; each d(l=2) subshell consists of five orbitals, and so forth.
- 3. The total number of orbitals in a shell is n^2 , where n is the principal quantum number of the shell. The resulting number of orbitals for the shells—1, 4, 9, 16—is related to a pattern seen in the periodic table: We see that the number of elements in the rows of the periodic table—2, 8, 18, and 32—equals twice these numbers. We will discuss this relationship further in Section 6.9.
- ▶ Figure 6.18 shows the relative energies of the hydrogen atom orbitals through n=3. Each box represents an orbital, and orbitals of the same subshell, such as the three 2p orbitals, are grouped together. When the electron occupies the lowest-energy orbital (1s), the hydrogen atom is said to be in its *ground state*. When the electron occupies any other orbital, the atom is in an *excited state*. (The electron can be excited to a higher-energy orbital by absorption of a photon of appropriate energy.) At ordinary temperatures, essentially all hydrogen atoms are in the ground state.

If the fourth shell (the n=4 energy level) were shown, how many subshells would it contain? How would they be labeled?

n = 1 shell has one orbital

n = 2 shell has two subshells composed of four orbitals

n = 3 shell has three subshells composed of nine orbitals

▲ Figure 6.18 Energy levels in the hydrogen atom.

Give It Some Thought

In Figure 6.18, why is the energy difference between the n=1 and n=2 levels much greater than the energy difference between the n=2 and n=3 levels?

SAMPLE EXERCISE 6.6

EXERCISE 6.6 Subshells of the Hydrogen Atom

(a) Without referring to Table 6.2, predict the number of subshells in the fourth shell, that is, for n = 4. (b) Give the label for each of these subshells. (c) How many orbitals are in each of these subshells?

SOLUTION

Analyze and Plan We are given the value of the principal quantum number, n. We need to determine the allowed values of l and m_l for this given value of n and then count the number of orbitals in each subshell.

Solve There are four subshells in the fourth shell, corresponding to the four possible values of l (0, 1, 2, and 3).

These subshells are labeled 4s, 4p, 4d, and 4f. The number given in the designation of a subshell is the principal quantum number, n; the letter designates the value of the angular momentum quantum number, l: for l = 0, s; for l = 1, p; for l = 2, d; for l = 3, f.

There is one 4s orbital (when l=0, there is only one possible value of m_l : 0). There are three 4p orbitals (when l=1, there are three possible values of m_l : 1, 0, -1). There are five 4d orbitals (when l=2, there are five allowed values of m_l : 2, 1, 0, -1, -2). There are seven 4f orbitals (when l=3, there are seven permitted values of m_l : 3, 2, 1, 0, -1, -2, -3).

Practice Exercise 1

An orbital has n = 4 and $m_l = -1$. What are the possible values of l for this orbital? (a) 0, 1, 2, 3 (b) -3, -2, -1, 0, 1, 2, 3 (c) 1, 2, 3 (d) -3, -2 (e) 1, 2, 3, 4

Practice Exercise 2

(a) What is the designation for the subshell with n=5 and l=1? (b) How many orbitals are in this subshell? (c) Indicate the values of m_l for each of these orbitals.

6.6 | Representations of Orbitals

So far we have emphasized orbital energies, but the wave function also provides information about an electron's probable location in space. Let's examine the ways in which we can picture orbitals because their shapes help us visualize how the electron density is distributed around the nucleus.

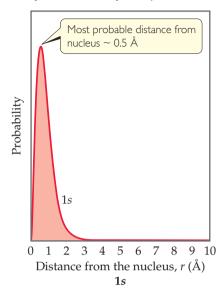

The s Orbitals

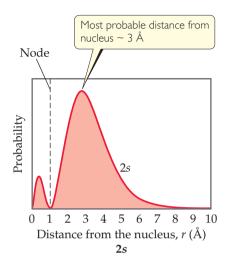

We have already seen one representation of the lowest-energy orbital of the hydrogen atom, the 1s (Figure 6.17). The first thing we notice about the electron density for the 1s orbital is that it is *spherically symmetric*—in other words, the electron density at a given distance from the nucleus is the same regardless of the direction in which we proceed from the nucleus. All of the other s orbitals (2s, 3s, 4s, and so forth) are also spherically symmetric and centered on the nucleus.

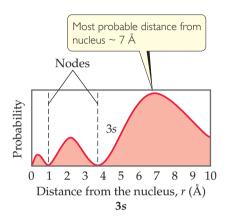

Recall that the l quantum number for the s orbitals is 0; therefore, the m_l quantum number must be 0. Thus, for each value of n, there is only one s orbital. So how do s orbitals differ as the value of n changes? For example, how does the electron-density distribution of the hydrogen atom change when the electron is excited from the 1s orbital to the 2s orbital? To address this question, we will look at the radial probability density, which is the probability that the electron is at a specific distance from the nucleus.

GO FIGURE

How many maxima would you expect to find in the radial probability function for the 4s orbital of the hydrogen atom? How many nodes would you expect in this function?

▲ Figure 6.19 Radial probability functions for the 1s, 2s, and 3s orbitals of hydrogen. These plots show the probability of finding the electron as a function of distance from the nucleus. As n increases, the most likely distance at which to find the electron (the highest peak) moves farther from the nucleus.

▲ Figure 6.19 shows the radial probability densities for the 1s, 2s, and 3s orbitals of hydrogen as a function of r, the distance from the nucleus—each resulting curve is the **radial probability function** for the orbital. Three features of these plots are noteworthy: the number of peaks, the number of points at which the probability function goes to zero (called **nodes**), and how spread out the distribution is, which gives a sense of the size of the orbital.

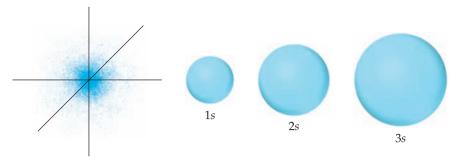

For the 1s orbital, we see that the probability rises rapidly as we move away from the nucleus, maximizing at about 0.5 Å. Thus, when the electron occupies the 1s orbital, it is *most likely* to be found this distance from the nucleus*—we still use the probabilistic description, consistent with the uncertainty principle. Notice also that in the 1s orbital the probability of finding the electron at a distance greater than about 3 Å from the nucleus is essentially zero.

Comparing the radial probability distributions for the 1s, 2s, and 3s orbitals reveals three trends:

- **1.** For an ns orbital, the number of peaks is equal to n, with the outermost peak being larger than inner ones.
- **2.** For an ns orbital, the number of nodes is equal to n-1.
- **3.** As n increases, the electron density becomes more spread out, that is, there is a greater probability of finding the electron further from the nucleus.

One widely used method of representing orbital *shape* is to draw a boundary surface that encloses some substantial portion, say 90%, of the electron density for the orbital. This type of drawing is called a *contour representation*, and the contour representations for the *s* orbitals are spheres (**Figure 6.20**). All the orbitals have the same shape, but they differ in size, becoming larger as *n* increases, reflecting the fact that the electron density becomes more spread out as *n* increases.

^{*}In the quantum mechanical model, the most probable distance at which to find the electron in the 1s orbital is actually 0.529 Å, the same as the radius of the orbit predicted by Bohr for n=1. The distance 0.529 Å is often called the Bohr radius.

(b) Contour models

▲ Figure 6.20 Comparison of the 1s, 2s, and 3s orbitals. (a) Electron-density distribution of a 1s orbital. (b) Contour representations of the 1s, 2s, and 3s orbitals. Each sphere is centered on the atom's nucleus and encloses the volume in which there is a 90% probability of finding the electron.

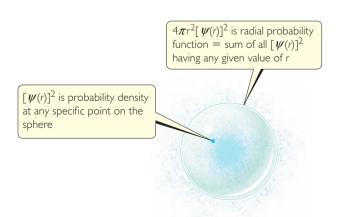

A Closer Look

Probability Density and Radial Probability Functions

According to quantum mechanics, we must describe the position of the electron in the hydrogen atom in terms of probabilities rather than exact locations. The information about the probability is contained in the wave functions, ψ , obtained from Schrödinger's equation. The square of the wave function, ψ^2 , called either the probability density or the electron density, as noted earlier, gives the probability that the electron is at any *point* in space. Because s orbitals are spherically symmetric, the value of ψ for an s electron depends only on its distance from the nucleus, r. Thus, the probability density can be written as $[\psi(r)]^2$, where $\psi(r)$ is the value of ψ at r. This function $[\psi(r)]^2$ gives the probability density for any point located a distance r from the nucleus.

The radial probability function, which we used in Figure 6.19, differs from the probability density. The radial probability function equals the *total* probability of finding the electron at all the points at any distance r from the nucleus. In other words, to calculate this function, we need to "add up" the probability densities $[\psi(r)]^2$ over all points located a distance r from the nucleus. \blacktriangledown Figure 6.21 compares the probability density at a point $[\psi(r)]^2$ with the radial probability function.

Let's examine the difference between probability density and radial probability function more closely. \triangleright Figure 6.22 shows plots of $[\psi(r)]^2$ as a function of r for the 1s, 2s, and 3s orbitals of the hydrogen atom. You will notice that these plots look distinctly different from the radial probability functions shown in Figure 6.19.

▲ Figure 6.21 Comparing probability density $[\psi(r)]^2$ and radial probability function $4\pi r^2 [\psi(r)]^2$.

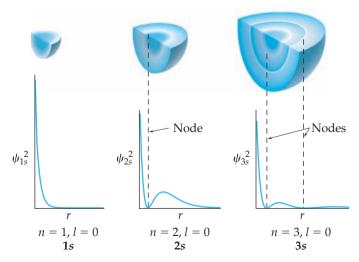

As shown in Figure 6.21, the collection of points a distance r from the nucleus is the surface of a sphere of radius r. The probability density $at\ each\ point$ on that spherical surface is $[\psi(r)]^2$. To add up all the individual probability densities requires calculus and so is beyond the scope of this text. However, the result of that calculation tells us that the radial probability function is the probability density, $[\psi(r)]^2$, multiplied by the surface area of the sphere, $4\pi r^2$:

Radial probability function at distance $r = 4\pi r^2 [\psi(r)]^2$

Thus, the plots of radial probability function in Figure 6.19 are equal to the plots of $[\psi(r)]^2$ in Figure 6.22 multiplied by $4\pi r^2$. The fact that $4\pi r^2$ increases rapidly as we move away from the nucleus makes the two sets of plots look very different from each other. For example, the plot of $[\psi(r)]^2$ for the 3s orbital in Figure 6.22 shows that the function generally gets smaller the farther we go from the nucleus. But when we multiply by $4\pi r^2$, we see peaks that get larger and larger as we move away from the nucleus (Figure 6.19).

The radial probability functions in Figure 6.19 provide us with the more useful information because they tell us the probability of finding the electron at all points a distance r from the nucleus, not just one particular point.

Related Exercises: 6.54, 6.65, 6.66, 6.98

▲ Figure 6.22 Probability density $[\psi(r)]^2$ in the 1s, 2s, and 3s orbitals of hydrogen.

Although the details of how electron density varies within a given contour representation are lost in these representations, this is not a serious disadvantage. For qualitative discussions, the most important features of orbitals are shape and relative size, which are adequately displayed by contour representations.

The p Orbitals

Recall that the orbitals for which l = 1 are the p orbitals. Each p subshell has three orbitals, corresponding to the three allowed values of m_l : -1, 0, and 1. The distribution of electron density for a 2p orbital is shown in ∇ Figure 6.23(a). The electron density is not distributed spherically as in an s orbital. Instead, the density is concentrated in two regions on either side of the nucleus, separated by a node at the nucleus. We say that this dumbbell-shaped orbital has two *lobes*. Recall that we are making no statement of how the electron is moving within the orbital. Figure 6.23(a) portrays only the *averaged* distribution of the electron density in a 2p orbital.

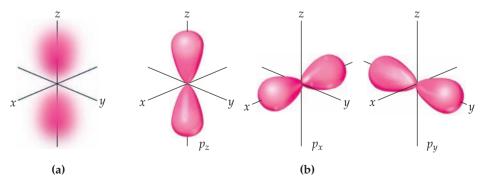

Beginning with the n=2 shell, each shell has three p orbitals (Table 6.2). Thus, there are three 2p orbitals, three 3p orbitals, and so forth. Each set of p orbitals has the dumbbell shapes shown in Figure 6.23(a) for the 2p orbitals. For each value of n, the three p orbitals have the same size and shape but differ from one another in spatial orientation. We usually represent p orbitals by drawing the shape and orientation of their wave functions, as shown in the contour representations in Figure 6.23(b). It is convenient to label these as p_x , p_y , and p_z orbitals. The letter subscript indicates the Cartesian axis along which the orbital is oriented.* Like s orbitals, p orbitals increase in size as we move from 2p to 3p to 4p, and so forth.

The d and f Orbitals

When n is 3 or greater, we encounter the d orbitals (for which l=2). There are five 3d orbitals, five 4d orbitals, and so forth, because in each shell there are five possible values for the m_l quantum number: -2, -1, 0, 1, and 2. The different d orbitals in a given shell have different shapes and orientations in space, as shown in Figure 6.24. Four of the d-orbital contour representations have a "four-leaf clover" shape, with four lobes, and each lies primarily in a plane. The d_{xy} , d_{xz} , and d_{yz} orbitals lie in the xy, xz, and yz planes,

▲ GO FIGURE

(a) Note on the left that the color is deep pink in the interior of each lobe but fades to pale pink at the edges. What does this change in color represent? (b) What label is applied to the 2p orbital aligned along the x axis?

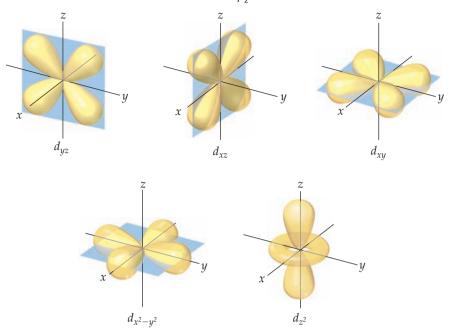

▲ Figure 6.23 The p orbitals. (a) Electron-density distribution of a 2p orbital. (b) Contour representations of the three p orbitals. The subscript on the orbital label indicates the axis along which the orbital lies.

^{*}We cannot make a simple correspondence between the subscripts (x, y, and z) and the allowed m_l values (1, 0, and -1). To explain why this is so is beyond the scope of an introductory text.

GO FIGURE

Which of the d orbitals most resembles a p_{τ} orbital?

▲ Figure 6.24 Contour representations of the five d orbitals.

respectively, with the lobes oriented *between* the axes. The lobes of the $d_{x^2-y^2}$ orbital also lie in the xy plane, but the lobes lie *along* the x and y axes. The d_{z^2} orbital looks very different from the other four: It has two lobes along the z axis and a "doughnut" in the xy plane. Even though the d_{z^2} orbital looks different from the other d orbitals, it has the same energy as the other four d orbitals. The representations in Figure 6.24 are commonly used for all d orbitals, regardless of the principal quantum number.

When n is 4 or greater, there are seven equivalent f orbitals (for which l=3). The shapes of the f orbitals are even more complicated than those of the d orbitals and are not presented here. As you will see in the next section, however, you must be aware of f orbitals as we consider the electronic structure of atoms in the lower part of the periodic table.

In many instances later in the text you will find that knowing the number and shapes of atomic orbitals will help you understand chemistry at the molecular level. You will therefore find it useful to memorize the shapes of the *s*, *p*, and *d* orbitals shown in Figures 6.20, 6.23, and 6.24.

6.7 | Many-Electron Atoms

One of our goals in this chapter has been to determine the electronic structures of atoms. So far, we have seen that quantum mechanics leads to an elegant description of the hydrogen atom. This atom, however, has only one electron. How does our description change when we consider an atom with two or more electrons (a *many-electron* atom)? To describe such an atom, we must consider the nature of orbitals and their relative energies as well as how the electrons populate the available orbitals.

Orbitals and Their Energies

We can describe the electronic structure of a many-electron atom by using the orbitals we described for the hydrogen atom in Table 6.2 (p. 229). Thus, the orbitals of a many-electron atom are designated 1s, $2p_x$, and so forth (Table 6.2), and have the same general shapes as the corresponding hydrogen orbitals.

Although the shapes of the orbitals of a many-electron atom are the same as those for hydrogen, the presence of more than one electron greatly changes the energies of the orbitals. In hydrogen the energy of an orbital depends only on its principal quantum number, n (Figure 6.18). For instance, in a hydrogen atom the 3s, 3p, and

3d subshells all have the same energy. In a many-electron atom, however, the energies of the various subshells in a given shell are *different* because of electron–electron repulsions. To explain why this happens, we must consider the forces between the electrons and how these forces are affected by the shapes of the orbitals. We will, however, forgo this analysis until Chapter 7.

The important idea is this: In a many-electron atom, for a given value of n, the energy of an orbital increases with increasing value of l, as illustrated in \triangleright Figure 6.25. For example, notice in Figure 6.25 that the n=3 orbitals increase in energy in the order 3s < 3p < 3d. Notice also that all orbitals of a given subshell (such as the five 3d orbitals) have the same energy, just as they do in the hydrogen atom. Orbitals with the same energy are said to be **degenerate**.

Figure 6.25 is a *qualitative* energy-level diagram; the exact energies of the orbitals and their spacings differ from one atom to another.

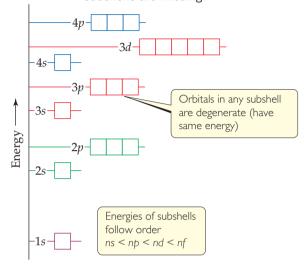

Give It Some Thought

In a many-electron atom, can we predict unambiguously whether the 4s orbital is lower or higher in energy than the 3d orbitals?

GO FIGURE

Not all of the orbitals in the n=4 shell are shown in this figure. Which subshells are missing?

▲ Figure 6.25 General energy ordering of orbitals for a many-electron atom.

Electron Spin and the Pauli Exclusion Principle

We have now seen that we can use hydrogen-like orbitals to describe many-electron atoms. What, however, determines which orbitals the electrons occupy? That is, how do the electrons of a many-electron atom populate the available orbitals? To answer this question, we must consider an additional property of the electron.

When scientists studied the line spectra of many-electron atoms in great detail, they noticed a very puzzling feature: Lines that were originally thought to be single were actually closely spaced pairs. This meant, in essence, that there were twice as many energy levels as there were "supposed" to be. In 1925 the Dutch physicists George Uhlenbeck and Samuel Goudsmit proposed a solution to this dilemma. They postulated that electrons have an intrinsic property, called **electron spin**, that causes each electron to behave as if it were a tiny sphere spinning on its own axis.

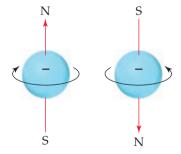

By now it may not surprise you to learn that electron spin is quantized. This observation led to the assignment of a new quantum number for the electron, in addition to n, l, and m_l , which we have already discussed. This new quantum number, the **spin magnetic quantum number**, is denoted m_s (the subscript s stands for spin). Two possible values are allowed for m_s , $+\frac{1}{2}$ or $-\frac{1}{2}$, which were first interpreted as indicating the two opposite directions in which the electron can spin. A spinning charge produces a magnetic field. The two opposite directions of spin therefore produce oppositely directed magnetic fields (\triangleright Figure 6.26).* These two opposite magnetic fields lead to the splitting of spectral lines into closely spaced pairs.

Electron spin is crucial for understanding the electronic structures of atoms. In 1925 the Austrian-born physicist Wolfgang Pauli (1900–1958) discovered the principle that governs the arrangement of electrons in many-electron atoms. The **Pauli exclusion principle** states that *no two electrons in an atom can have the same set of four*

A GO FIGURE

From this figure, why are there only two possible values for the spin quantum number?

▲ Figure 6.26 Electron spin. The electron behaves as if it were spinning about an axis, thereby generating a magnetic field whose direction depends on the direction of spin. The two directions for the magnetic field correspond to the two possible values for the spin quantum number, m_s .

^{*}As we discussed earlier, the electron has both particle-like and wave-like properties. Thus, the picture of an electron as a spinning charged sphere is, strictly speaking, just a useful pictorial representation that helps us understand the two directions of magnetic field that an electron can possess.

quantum numbers n, l, m_l , and m_s . For a given orbital, the values of n, l, and m_l are fixed. Thus, if we want to put more than one electron in an orbital and satisfy the Pauli exclusion principle, our only choice is to assign different m_s values to the electrons. Because there are only two such values, we conclude that an orbital can hold a maximum of two electrons and they must have opposite spins. This restriction allows us to index the electrons in an atom, giving their quantum numbers and thereby defining the region in space where each electron is most likely to be found. It also provides the key to understanding the remarkable structure of the periodic table of the elements.

Chemistry and Life

Nuclear Spin and Magnetic Resonance Imaging

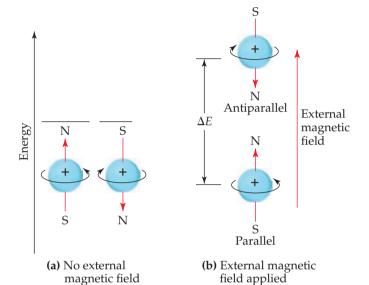

A major challenge facing medical diagnosis is seeing inside the human body. Until recently, this was accomplished primarily by X-ray technology. X rays do not, however, give well-resolved images of overlapping physiological structures, and sometimes fail to discern diseased or injured tissue. Moreover, because X rays are high-energy radiation, they potentially can cause physiological harm, even in low doses. An imaging technique developed in the 1980s called *magnetic resonance imaging (MRI)* does not have these disadvantages.

The foundation of MRI is a phenomenon called *nuclear magnetic resonance* (*NMR*), which was discovered in the mid-1940s. Today NMR has become one of the most important spectroscopic methods used in chemistry. NMR is based on the observation that, like electrons, the nuclei of many elements possess an intrinsic spin. Like electron spin, nuclear spin is quantized. For example, the nucleus of ${}^{1}H$ has two possible magnetic nuclear spin quantum numbers, $+\frac{1}{2}$ and $-\frac{1}{2}$.

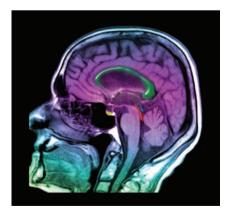

A spinning hydrogen nucleus acts like a tiny magnet. In the absence of external effects, the two spin states have the same energy. However, when the nuclei are placed in an external magnetic field, they can align either parallel or opposed (antiparallel) to the field, depending on their spin. The parallel alignment is lower in energy than the antiparallel one by a certain amount, ΔE (\blacktriangleright Figure 6.27). If the nuclei are irradiated with photons having energy equal to ΔE , the spin of the nuclei can be "flipped," that is, excited from the parallel to the antiparallel alignment. Detection of the flipping of nuclei between the two spin states leads to an NMR spectrum. The radiation used in an NMR experiment is in the radiofrequency range, typically 100 to 900 MHz, which is far less energetic per photon than X rays.

Because hydrogen is a major constituent of aqueous body fluids and fatty tissue, the hydrogen nucleus is the most convenient one for study by MRI. In MRI a person's body is placed in a strong magnetic field. By irradiating the body with pulses of radiofrequency radiation and using sophisticated detection techniques, medical technicians can image tissue at specific depths in the body, giving pictures with spectacular detail (**Figure 6.28**). The ability to sample at different depths allows the technicians to construct a three-dimensional picture of the body.

MRI has had such a profound influence on the modern practice of medicine that Paul Lauterbur, a chemist, and Peter Mansfield, a physicist, were awarded the 2003 Nobel Prize in Physiology or Medicine for their discoveries concerning MRI. The major drawback of this technique is expense: The current cost of a new standard MRI instrument for clinical applications is typically \$1.5 million. In the 2000s, a new technique was developed, called *prepolarized MRI*, that requires

▲ Figure 6.27 Nuclear spin. Like electron spin, nuclear spin generates a small magnetic field and has two allowed values. (a) In the absence of an external magnetic field, the two spin states have the same energy. (b) When an external magnetic field is applied, the spin state in which the spin direction is parallel to the direction of the external field is lower in energy than the spin state in which the spin direction is antiparallel to the field direction. The energy difference, ΔE , is in the radio frequency portion of the electromagnetic spectrum.

▲ Figure 6.28 MRI image. This image of a human head, obtained using magnetic resonance imaging, shows a normal brain, airways, and facial tissues.

much less expensive equipment and will lead to an even greater application of this important diagnostic tool.

Related Exercise: 6.100

6.8 | Electron Configurations

Armed with knowledge of the relative energies of orbitals and the Pauli exclusion principle, we are in a position to consider the arrangements of electrons in atoms. The way electrons are distributed among the various orbitals of an atom is called the **electron configuration** of the atom.

The most stable electron configuration—the ground state—is that in which the electrons are in the lowest possible energy states. If there were no restrictions on the possible values for the quantum numbers of the electrons, all the electrons would crowd into the 1s orbital because it is the lowest in energy (Figure 6.25). The Pauli exclusion principle tells us, however, that there can be at most two electrons in any single orbital. Thus, the orbitals are filled in order of increasing energy, with no more than two electrons per orbital. For example, consider the lithium atom, which has three electrons. (Recall that the number of electrons in a neutral atom equals its atomic number.) The 1s orbital can accommodate two of the electrons. The third one goes into the next lowest-energy orbital, the 2s.

We can represent any electron configuration by writing the symbol for the occupied subshell and adding a superscript to indicate the number of electrons in that subshell. For example, for lithium we write $1s^22s^1$ (read "1s two, 2s one"). We can also show the arrangement of the electrons as

In this representation, which we call an **orbital diagram**, each orbital is denoted by a box and each electron by a half arrow. A half arrow pointing up (1) represents an electron with a positive spin magnetic quantum number $(m_s = +\frac{1}{2})$, and a half arrow pointing down (1) represents an electron with a negative spin magnetic quantum number $(m_s = -\frac{1}{2})$. This pictorial representation of electron spin, which corresponds to the directions of the magnetic fields in Figure 6.26, is quite convenient. Chemists refer to the two possible spin states as "spin-up" and "spin-down" corresponding to the directions of the half arrows.

Electrons having opposite spins are said to be *paired* when they are in the same orbital (1). An *unpaired electron* is one not accompanied by a partner of opposite spin. In the lithium atom the two electrons in the 1s orbital are paired and the electron in the 2s orbital is unpaired.

Hund's Rule

Consider now how the electron configurations of the elements change as we move from element to element across the periodic table. Hydrogen has one electron, which occupies the 1s orbital in its ground state:

$$H \qquad \boxed{\frac{1}{1}} : 1s^1$$

The choice of a spin-up electron here is arbitrary; we could equally well show the ground state with one spin-down electron. It is customary, however, to show unpaired electrons with their spins up.

The next element, helium, has two electrons. Because two electrons with opposite spins can occupy the same orbital, both of helium's electrons are in the 1s orbital:

He
$$1 : 1s^2$$

The two electrons present in helium complete the filling of the first shell. This arrangement represents a very stable configuration, as is evidenced by the chemical inertness of helium.

The electron configurations of lithium and several elements that follow it in the periodic table are shown in ∇ **Table 6.3**. For the third electron of lithium, the change in the principal quantum number from n=1 for the first two electrons to n=2 for the third electron represents a large jump in energy and a corresponding jump in the average distance of the electron from the nucleus. In other words, it represents the start of a new shell occupied with electrons. As you can see by examining the periodic table, lithium starts a new row of the table. It is the first member of the alkali metals (group 1A).

The element that follows lithium is beryllium; its electron configuration is $1s^22s^2$ (Table 6.3). Boron, atomic number 5, has the electron configuration $1s^22s^22p^1$. The fifth electron must be placed in a 2p orbital because the 2s orbital is filled. Because all three of the 2p orbitals are of equal energy, it does not matter which 2p orbital we place this fifth electron in.

With the next element, carbon, we encounter a new situation. We know that the sixth electron must go into a 2p orbital. However, does this new electron go into the 2p orbital that already has one electron or into one of the other two 2p orbitals? This question is answered by **Hund's rule**, which states that *for degenerate orbitals, the lowest energy is attained when the number of electrons having the same spin is maximized.* This means that electrons occupy orbitals singly to the maximum extent possible and that these single electrons in a given subshell all have the same spin magnetic quantum number. Electrons arranged in this way are said to have *parallel spins*. For a carbon atom to achieve its lowest energy, therefore, the two 2p electrons must have the same spin. For this to happen, the electrons must be in different 2p orbitals, as shown in Table 6.3. Thus, a carbon atom in its ground state has two unpaired electrons.

Similarly, for nitrogen in its ground state, Hund's rule requires that the three 2*p* electrons singly occupy each of the three 2*p* orbitals. This is the only way that all three electrons can have the same spin. For oxygen and fluorine, we place four and five electrons, respectively, in the 2*p* orbitals. To achieve this, we pair up electrons in the 2*p* orbitals, as we will see in Sample Exercise 6.7.

Hund's rule is based in part on the fact that electrons repel one another. By occupying different orbitals, the electrons remain as far as possible from one another, thus minimizing electron–electron repulsions.

Table 6.3	Electron Conf	igurations of Several Lighter E	lements
Element	Total Electrons	Orbital Diagram	Electron Configuration
		1s 2s 2p 3s	
Li	3	1 1	$1s^22s^1$

Na	11	11 11 11 11 1	$1s^22s^22p^63s^1$

SAMPLE EXERCISE 6.7 Orbital Diagrams and Electron Configurations

Draw the orbital diagram for the electron configuration of oxygen, atomic number 8. How many unpaired electrons does an oxygen atom possess?

SOLUTION

Analyze and Plan Because oxygen has an atomic number of 8, each oxygen atom has eight electrons. Figure 6.25 shows the ordering of orbitals. The electrons (represented as half arrows) are placed in the orbitals (represented as boxes) beginning with the lowest-energy orbital, the 1s. Each orbital can hold a maximum of two electrons (the Pauli exclusion principle). Because the 2p orbitals are degenerate, we place one electron in each of these orbitals (spin-up) before pairing any electrons (Hund's rule).

Solve Two electrons each go into the 1s and 2s orbitals with their spins paired. This leaves four electrons for the three degenerate 2p orbitals. Following Hund's rule, we put one electron into each 2p orbital until all three orbitals have one electron each. The fourth electron is then paired up with one of the three electrons already in a 2p orbital, so that the orbital diagram is

The corresponding electron configuration is written $1s^22s^22p^4$. The atom has two unpaired electrons.

Practice Exercise 1

How many of the elements in the second row of the periodic table (Li through Ne) will have at least one unpaired electron in their electron configurations? (a) 3 (b) 4 (c) 5 (d) 6 (e) 7

Practice Exercise 2

(a) Write the electron configuration for silicon, element 14, in its ground state. (b) How many unpaired electrons does a ground-state silicon atom possess?

Condensed Electron Configurations

The filling of the 2p subshell is complete at neon (Table 6.3), which has a stable configuration with eight electrons (an octet) in the outermost occupied shell. The next element, sodium, atomic number 11, marks the beginning of a new row of the periodic table. Sodium has a single 3s electron beyond the stable configuration of neon. We can therefore abbreviate the electron configuration of sodium as

Na:
$$[Ne]3s^1$$

The symbol [Ne] represents the electron configuration of the ten electrons of neon, $1s^22s^22p^6$. Writing the electron configuration as [Ne]3 s^1 focuses attention on the outermost electron of the atom, which is the one largely responsible for how sodium behaves chemically.

We can generalize what we have just done for the electron configuration of sodium. In writing the *condensed electron configuration* of an element, the electron configuration of the nearest noble-gas element of lower atomic number is represented by its chemical symbol in brackets. For lithium, for example, we can write

Li:
$$[He]^2s^1$$

We refer to the electrons represented by the bracketed symbol as the *noble-gas core* of the atom. More usually, these inner-shell electrons are referred to as the **core electrons**. The electrons given after the noble-gas core are called the *outer-shell electrons*. The outer-shell electrons include the electrons involved in chemical bonding, which are called the **valence electrons**. For the elements with atomic number of 30 or less, all of the outer-shell electrons are valence electrons. By comparing the condensed electron configurations of lithium and sodium, we can appreciate why these two elements are so

1 A 3 Li [He]2s 11 Na Ne]3s 19 K [Ar]4s 37 Rb [Kr]5s 55 Cs [Xe]6s 87 Fr $[Rn]7s^1$

Alkali metals

▲ Figure 6.29 The condensed electron configurations of the alkali metals (group 1A in the periodic table).

similar chemically. They have the same type of electron configuration in the outermost occupied shell. Indeed, all the members of the alkali metal group (1A) have a single s valence electron beyond a noble-gas configuration (\blacktriangleleft Figure 6.29).

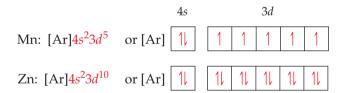

Transition Metals

The noble-gas element argon $(1s^22s^22p^63s^23p^6)$ marks the end of the row started by sodium. The element following argon in the periodic table is potassium (K), atomic number 19. In all its chemical properties, potassium is clearly a member of the alkali metal group. The experimental facts about the properties of potassium leave no doubt that the outermost electron of this element occupies an s orbital. But this means that the electron with the highest energy has *not* gone into a 3d orbital, which we might expect it to do. Because the 4s orbital is lower in energy than the 3d orbital (Figure 6.25), the condensed electron configuration of potassium is

K:
$$[Ar]4s^1$$

Following the complete filling of the 4s orbital (this occurs in the calcium atom), the next set of orbitals to be filled is the 3d. (You will find it helpful as we go along to refer often to the periodic table on the front-inside cover.) Beginning with scandium and extending through zinc, electrons are added to the five 3d orbitals until they are completely filled. Thus, the fourth row of the periodic table is ten elements wider than the two previous rows. These ten elements are known as either **transition elements** or **transition metals**. Note the position of these elements in the periodic table.

In writing the electron configurations of the transition elements, we fill orbitals in accordance with Hund's rule—we add them to the 3d orbitals singly until all five orbitals have one electron each and then place additional electrons in the 3d orbitals with spin pairing until the shell is completely filled. The condensed electron configurations and the corresponding orbital diagram representations of two transition elements are as follows:

Once all the 3d orbitals have been filled with two electrons each, the 4p orbitals begin to be occupied until the completed octet of outer electrons ($4s^24p^6$) is reached with krypton (Kr), atomic number 36, another of the noble gases. Rubidium (Rb) marks the beginning of the fifth row. Refer again to the periodic table on the front-inside cover. Notice that this row is in every respect like the preceding one, except that the value for n is greater by 1.

Give It Some Thought

Based on the structure of the periodic table, which becomes occupied first, the 6s orbital or the 5d orbitals?

The Lanthanides and Actinides

The sixth row of the periodic table begins with Cs and Ba, which have $[Xe]6s^1$ and $[Xe]6s^2$ configurations, respectively. Notice, however, that the periodic table then has a break, with elements 57–70 placed below the main portion of the table. This break point is where we begin to encounter a new set of orbitals, the 4f.

There are seven degenerate 4f orbitals, corresponding to the seven allowed values of m_l , ranging from 3 to -3. Thus, it takes 14 electrons to fill the 4f orbitals completely. The 14 elements corresponding to the filling of the 4f orbitals are known as either the **lanthanide elements** or the **rare earth elements**. These elements are set below the

other elements to avoid making the periodic table unduly wide. The properties of the lanthanide elements are all quite similar, and these elements occur together in nature. For many years it was virtually impossible to separate them from one another.

Because the energies of the 4f and 5d orbitals are very close to each other, the electron configurations of some of the lanthanides involve 5d electrons. For example, the elements lanthanum (La), cerium (Ce), and praseodymium (Pr) have the following electron configurations:

 $[Xe]6s^25d^1$ $[Xe]6s^25d^14f^1$ $[Xe]6s^24f^3$ Lanthanum Cerium Praseodymium

Because La has a single 5d electron, it is sometimes placed below yttrium (Y) as the first member of the third series of transition elements; Ce is then placed as the first member of the lanthanides. Based on its chemical properties, however, La can be considered the first element in the lanthanide series. Arranged this way, there are fewer apparent exceptions to the regular filling of the 4f orbitals among the subsequent members of the series.

After the lanthanide series, the third transition element series is completed by the filling of the 5d orbitals, followed by the filling of the 6p orbitals. This brings us to radon (Rn), heaviest of the known noble-gas elements.

The final row of the periodic table begins by filling the 7*s* orbitals. The **actinide elements**, of which uranium (U, element 92) and plutonium (Pu, element 94) are the best known, are then built up by completing the 5*f* orbitals. All of the actinide elements are radioactive, and most of them are not found in nature.

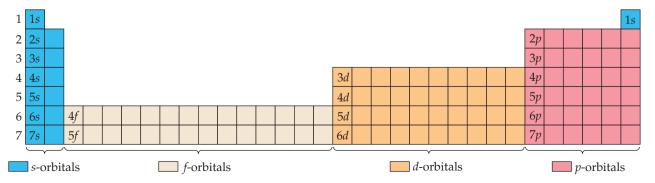

6.9 | Electron Configurations and the Periodic Table

We just saw that the electron configurations of the elements correspond to their locations in the periodic table. Thus, elements in the same column of the table have related outer-shell (valence) electron configurations. As \triangleright Table 6.4 shows, for example, all 2A elements have an ns^2 outer configuration, and all 3A elements have an ns^2np^1 outer configuration, with the value of n increasing as we move down each column.

In Table 6.2 we saw that the total number of orbitals in each shell equals n^2 : 1, 4, 9, or 16. Because we can place two electrons in each orbital, each shell accommodates up to $2n^2$ electrons: 2, 8, 18, or 32. We see that the overall structure of the periodic table reflects these electron numbers: Each row of the table has 2, 8, 18, or 32 elements in it. As shown in ∇ Figure 6.30, the periodic table can be further divided into four blocks based on the filling order of orbitals. On the left are *two* blue columns of elements. These elements, known as the alkali metals (group 1A) and alkaline earth metals (group 2A), are those in which the valence *s* orbitals are being filled. These two columns make up the *s* block of the periodic table.

Table 6.4 Electron Configurations of Group 2A and 3A Elements

▲ Figure 6.30 Regions of the periodic table. The order in which electrons are added to orbitals is read left to right beginning in the top-left corner.

On the right is a block of *six* pink columns that comprises the *p* block, where the valence *p* orbitals are being filled. The *s* block and the *p* block elements together are the **representative elements**, sometimes called the **main-group elements**.

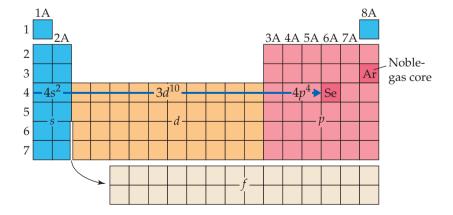

The orange block in Figure 6.30 has *ten* columns containing the transition metals. These are the elements in which the valence d orbitals are being filled and make up the d block.

The elements in the two tan rows containing 14 columns are the ones in which the valence f orbitals are being filled and make up the f block. Consequently, these elements are often referred to as the f-block metals. In most tables, the f block is positioned below the periodic table to save space:

The number of columns in each block corresponds to the maximum number of electrons that can occupy each kind of subshell. Recall that 2, 6, 10, and 14 are the numbers of electrons that can fill the s, p, d, and f subshells, respectively. Thus, the s block has 2 columns, the p block has 6, the d block has 10, and the f block has 14. Recall also that 1s is the first s subshell, 2p is the first p subshell, 3d is the first d subshell, and 4f is the first f subshell, as Figure 6.30 shows. Using these facts, you can write the electron configuration of an element based merely on its position in the periodic table. Remember: The periodic table is your best guide to the order in which orbitals are filled.

Let's use the periodic table to write the electron configuration of selenium (Se, element 34). We first locate Se in the table and then move backward from it through the table, from element 34 to 33 to 32, and so forth, until we come to the noble gas that precedes Se. In this case, the noble gas is argon, Ar, element 18. Thus, the noble-gas core for Se is [Ar]. Our next step is to write symbols for the outer electrons. We do this by moving across period 4 from K, the element following Ar, to Se:

Because K is in the fourth period and the *s* block, we begin with the 4*s* electrons, meaning our first two outer electrons are written $4s^2$. We then move into the *d* block, which begins with the 3*d* electrons. (The principal quantum number in the *d* block is always one less than that of the preceding elements in the *s* block, as seen in Figure 6.30.)

Traversing the d block adds ten electrons, $3d^{10}$. Finally, we move into the p block, whose principal quantum number is always the same as that of the s block. Counting the squares as we move across the p block to Se tells us that we need four electrons, $4p^4$. The electron configuration for Se is therefore $[Ar]4s^23d^{10}4p^4$. This configuration can also be written with the subshells arranged in order of increasing principal quantum number: $[Ar]3d^{10}4s^24p^4$.

As a check, we add the number of electrons in the [Ar] core, 18, to the number of electrons we added to the 4s, 3d, and 4p subshells. This sum should equal the atomic number of Se, 34:18+2+10+4=34.

SAMPLE EXERCISE 6.8 Electron Configurations for a Group

What is the characteristic valence electron configuration of the group 7A elements, the halogens?

SOLUTION

Analyze and Plan We first locate the halogens in the periodic table, write the electron configurations for the first two elements, and then determine the general similarity between the configurations.

Solve The first member of the halogen group is fluorine (F, element 9). Moving backward from F, we find that the noble-gas core is [He]. Moving from He to the element of next higher atomic number brings us to Li, element 3. Because Li is in the second period of the s block, we add electrons to the 2s subshell. Moving across this block gives $2s^2$. Continuing to move to the right, we enter the p block. Counting the squares to F gives $2p^5$. Thus, the condensed electron configuration for fluorine is

F:
$$[He]_{2s^22p^5}$$

The electron configuration for chlorine, the second halogen, is

Cl:
$$[Ne] 3s^2 3p^5$$

From these two examples, we see that the characteristic valence electron configuration of a halogen is ns^2np^5 , where n ranges from 2 in the case of fluorine to 6 in the case of astatine.

Practice Exercise 1

A certain atom has an ns^2np^6 electron configuration in its outermost occupied shell. Which of the following elements could it be? (a) Be (b) Si (c) I (d) Kr (e) Rb

Practice Exercise 2

Which family of elements is characterized by an ns^2np^2 electron configuration in the outermost occupied shell?

SAMPLE EXERCISE 6.9 Electron Configurations from the Periodic Table

(a) Based on its position in the periodic table, write the condensed electron configuration for bismuth, element 83. (b) How many unpaired electrons does a bismuth atom have?

SOLUTION

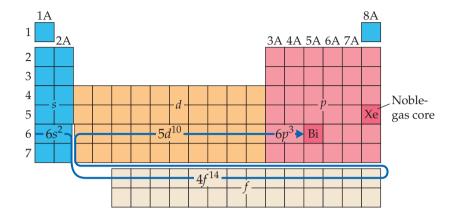

(a) Our first step is to write the noble-gas core. We do this by locating bismuth, element 83, in the periodic table. We then move backward to the nearest noble gas, which is Xe, element 54. Thus, the noble-gas core is [Xe].

Next, we trace the path in order of increasing atomic numbers from Xe to Bi. Moving from Xe to Cs, element 55, we find ourselves in period 6 of the s block. Knowing the block and the period identifies the subshell in which we begin placing outer electrons, 6s. As we move through the s block, we add two electrons: $6s^2$.

As we move beyond the s block, from element 56 to element 57, the curved arrow below the periodic table reminds us that we are entering the f block. The first row of the f block corresponds to the 4f subshell. As we move across this block, we add 14 electrons: $4f^{14}$.

With element 71, we move into the third row of the d block. Because the first row of the d block is 3d, the second row is 4d and the third row is 5d. Thus, as we move through the ten elements of the d block, from element 71 to element 80, we fill the 5d subshell with ten electrons: $5d^{10}$.

Moving from element 80 to element 81 puts us into the p block in the 6p subshell. (Remember that the principal quantum number in the p block is the same as that in the p block.) Moving across to Bi requires three electrons: $6p^3$. The path we have taken is

Putting the parts together, we obtain the condensed electron configuration: $[Xe]6s^24f^{14}5d^{10}6p^3$. This configuration can also be written with the subshells arranged in order of increasing principal quantum number: $[Xe]4f^{14}5d^{10}6s^26p^3$.

Finally, we check our result to see if the number of electrons equals the atomic number of Bi, 83: Because Xe has 54 electrons (its atomic number), we have 54 + 2 + 14 + 10 + 3 = 83. (If we had 14 electrons too few, we would realize that we have missed the *f* block.)

(b) We see from the condensed electron configuration that the only partially occupied subshell is 6*p*. The orbital diagram representation for this subshell is

In accordance with Hund's rule, the three 6*p* electrons occupy the three 6*p* orbitals singly, with their spins parallel. Thus, there are three unpaired electrons in the bismuth atom.

Practice Exercise 1

A certain atom has an [noble gas] $5s^24d^{10}5p^4$ electron configuration. Which element is it? (a) Cd (b) Te (c) Sm (d) Hg (e) More information is needed

Practice Exercise 2

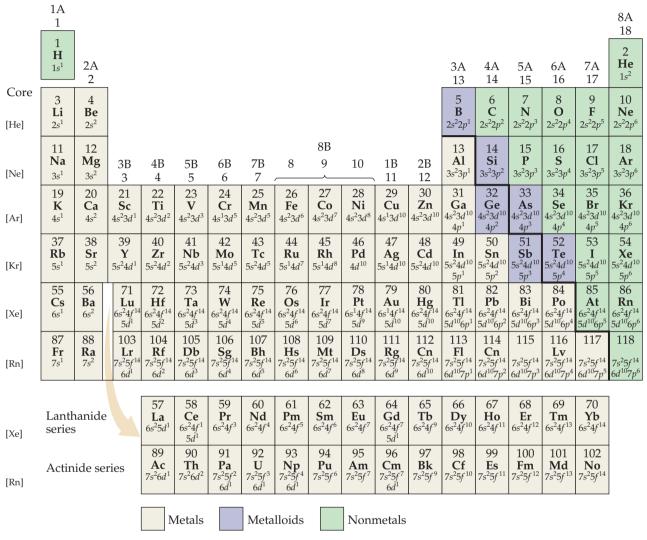

Use the periodic table to write the condensed electron configuration for (a) Co (element 27), (b) In (element 49).

Figure 6.31 gives, for all the elements, the ground-state electron configurations for the outer-shell electrons. You can use this figure to check your answers as you practice writing electron configurations. We have written these configurations with orbitals listed in order of increasing principal quantum number. As we saw in Sample Exercise 6.9, the orbitals can also be listed in order of filling, as they would be read off of the periodic table.

Figure 6.31 allow us to reexamine the concept of *valence electrons*. Notice, for example, that as we proceed from Cl ([Ne] $3s^23p^5$) to Br ([Ar] $3d^{10}4s^24p^5$) we add a complete subshell of 3d electrons to the electrons beyond the [Ar] core. Although the 3d electrons are outer-shell electrons, they are not involved in chemical bonding and are therefore not considered valence electrons. Thus, we consider only the 4s and 4p electrons of Br to be valence electrons. Similarly, if we compare the electron configurations of Ag (element 47) and Au (element 79), we see that Au has a completely full $4f^{14}$ subshell beyond its noble-gas core, but those 4f electrons are not involved in bonding. In general, for representative elements we do not consider the electrons in completely filled d or f subshells to be valence electrons, and for transition elements we do not consider the electrons in a completely filled f subshell to be valence electrons.

A GO FIGURE

A friend tells you that her favorite element has an electron configuration of [noble gas] $6s^24f^{14}5d^6$. Which element is it?

▲ Figure 6.31 Outer-shell electron configurations of the elements.

Anomalous Electron Configurations

The electron configurations of certain elements appear to violate the rules we have just discussed. For example, Figure 6.31 shows that the electron configuration of chromium (element 24) is $[Ar]3d^54s^1$ rather than the $[Ar]3d^44s^2$ configuration we might expect. Similarly, the configuration of copper (element 29) is $[Ar]3d^{10}4s^{1}$ instead of $[Ar]3d^{9}4s^{2}$.

This anomalous behavior is largely a consequence of the closeness of the 3d and 4s orbital energies. It frequently occurs when there are enough electrons to form precisely half-filled sets of degenerate orbitals (as in chromium) or a completely filled d subshell (as in copper). There are a few similar cases among the heavier transition metals (those with partially filled 4d or 5d orbitals) and among the f-block metals. Although these minor departures from the expected are interesting, they are not of great chemical significance.

Give It Some Thought

The elements Ni, Pd, and Pt are all in the same group. By examining the electron configurations for these elements in Figure 6.31, what can you conclude about the relative energies of the *nd* and (n + 1)s orbitals for this group?

SAMPLE INTEGRATIVE EXERCISE

Putting Concepts Together

Boron, atomic number 5, occurs naturally as two isotopes, ^{10}B and ^{11}B , with natural abundances of 19.9% and 80.1%, respectively. (a) In what ways do the two isotopes differ from each other? Does the electronic configuration of ^{10}B differ from that of ^{11}B ? (b) Draw the orbital diagram for an atom of ^{11}B . Which electrons are the valence electrons? (c) Indicate three major ways in which the 1s electrons in boron differ from its 2s electrons. (d) Elemental boron reacts with fluorine to form BF₃, a gas. Write a balanced chemical equation for the reaction of solid boron with fluorine gas. (e) ΔH_f° for BF₃(g) is -1135.6 kJ/mol. Calculate the standard enthalpy change in the reaction of boron with fluorine. (f) Will the mass percentage of F be the same in $^{10}\text{BF}_3$ and $^{11}\text{BF}_3$? If not, why is that the case?

SOLUTION

- (a) The two isotopes of boron differ in the number of neutrons in the nucleus. ∞ (Sections 2.3 and 2.4) Each of the isotopes contains five protons, but 10 B contains five neutrons, whereas 11 B contains six neutrons. The two isotopes of boron have identical electron configurations, $1s^22s^22p^1$, because each has five electrons.
- (b) The complete orbital diagram is

The valence electrons are the ones in the outermost occupied shell, the $2s^2$ and $2p^1$ electrons. The $1s^2$ electrons constitute the core electrons, which we represent as [He] when we write the condensed electron configuration, [He] $2s^22p^1$.

(c) The 1s and 2s orbitals are both spherical, but they differ in three important respects: First, the 1s orbital is lower in energy than the

2s orbital. Second, the average distance of the 2s electrons from the nucleus is greater than that of the 1s electrons, so the 1s orbital is smaller than the 2s. Third, the 2s orbital has one node, whereas the 1s orbital has no nodes (Figure 6.19).

(d) The balanced chemical equation is

$$2 B(s) + 3 F_2(g) \longrightarrow 2 BF_3(g)$$

- (e) $\Delta H^\circ = 2(-1135.6) [0 + 0] = -2271.2$ kJ. The reaction is strongly exothermic.
- (f) As we saw in Equation 3.10 (Section 3.3), the mass percentage of an element in a substance depends on the formula weight of the substance. The formula weights of ¹⁰BF₃ and ¹¹BF₃ are different because of the difference in the masses of the two isotopes (the isotope masses of ¹⁰B and ¹¹B are 10.01294 and 11.00931 amu, respectively). The denominators in Equation 3.10 would therefore be different for the two isotopes, whereas the numerators would remain the same.

Chapter Summary and Key Terms

WAVELENGTHS AND FREQUENCIES OF LIGHT (INTRODUCTION AND SECTION 6.1) The electronic structure of an atom describes the energies and arrangement of electrons around the atom. Much of what is known about the electronic structure of atoms was obtained by observing the interaction of light with matter.

Visible light and other forms of **electromagnetic radiation** (also known as radiant energy) move through a vacuum at the speed of light, $c=2.998\times 10^8\,\mathrm{m/s}$. Electromagnetic radiation has both electric and magnetic components that vary periodically in wave-like fashion. The wave characteristics of radiant energy allow it to be described in terms of **wavelength**, λ , and **frequency**, ν , which are interrelated: $\lambda \nu = c$.

QUANTIZED ENERGY AND PHOTONS (SECTION 6.2) Planck proposed that the minimum amount of radiant energy that an object can gain or lose is related to the frequency of the radiation: $E = h\nu$. This smallest quantity is called a **quantum** of energy. The constant h is called **Planck constant**: $h = 6.626 \times 10^{-34}$ J-s.

In the quantum theory, energy is quantized, meaning that it can have only certain allowed values. Einstein used the quantum theory to explain the **photoelectric effect**, the emission of electrons from metal surfaces when exposed to light. He proposed that light behaves as if it consists of quantized energy packets called **photons**. Each photon carries energy, $E = h\nu$.

BOHR MODEL OF THE HYDROGEN ATOM (SECTION 6.3) Dispersion of radiation into its component wavelengths produces a **spectrum**. If the spectrum contains all wavelengths, it is called a **continuous spectrum**; if it contains only certain specific wavelengths, the spectrum is called a **line spectrum**. The radiation emitted by excited hydrogen atoms forms a line spectrum.

Bohr proposed a model of the hydrogen atom that explains its line spectrum. In this model the energy of the electron in the hydrogen atom depends on the value of a quantum number, n, called the

principal quantum number. The value of n must be a positive integer $(1, 2, 3, \ldots)$, and each value of n corresponds to a different specific energy, E_n . The energy of the atom increases as n increases. The lowest energy is achieved for n=1; this is called the **ground state** of the hydrogen atom. Other values of n correspond to **excited states**. Light is emitted when the electron drops from a higher-energy state to a lower-energy state; light is absorbed to excite the electron from a lower energy state to a higher one. The frequency of light emitted or absorbed is such that $h\nu$ equals the difference in energy between two allowed states.

WAVE BEHAVIOR OF MATTER (SECTION 6.4) De Broglie proposed that matter, such as electrons, should exhibit wave-like properties. This hypothesis of **matter waves** was proved experimentally by observing the diffraction of electrons. An object has a characteristic wavelength that depends on its **momentum**, mv: $\lambda = h/mv$.

Discovery of the wave properties of the electron led to Heisenberg's uncertainty principle, which states that there is an inherent limit to the accuracy with which the position and momentum of a particle can be measured simultaneously.

QUANTUM MECHANICS AND ORBITALS (SECTION 6.5) In the quantum mechanical model of the hydrogen atom, the behavior of the electron is described by mathematical functions called **wave functions**, denoted with the Greek letter ψ . Each allowed wave function has a precisely known energy, but the location of the electron cannot be determined exactly; rather, the probability of it being at a particular point in space is given by the **probability density**, ψ^2 . The **electron density** distribution is a map of the probability of finding the electron at all points in space.

The allowed wave functions of the hydrogen atom are called **orbitals**. An orbital is described by a combination of an integer and a letter, corresponding to values of three quantum numbers. The *principal quantum number*, n, is indicated by the integers $1, 2, 3, \ldots$ This quantum

number relates most directly to the size and energy of the orbital. The **angular momentum quantum number**, l, is indicated by the letters s, p, d, f, and so on, corresponding to the values of 0, 1, 2, 3, The l quantum number defines the shape of the orbital. For a given value of n, l can have integer values ranging from 0 to (n-1). The **magnetic quantum number**, m_l , relates to the orientation of the orbital in space. For a given value of l, m_l can have integral values ranging from -l to l, including 0. Subscripts can be used to label the orientations of the orbitals. For example, the three 3p orbitals are designated $3p_{xy}$ $3p_{yy}$ and $3p_{zy}$ with the subscripts indicating the axis along which the orbital is oriented.

An electron shell is the set of all orbitals with the same value of n, such as 3s, 3p, and 3d. In the hydrogen atom all the orbitals in an electron shell have the same energy. A **subshell** is the set of one or more orbitals with the same n and l values; for example, 3s, 3p, and 3d are each subshells of the n=3 shell. There is one orbital in an s subshell, three in a p subshell, five in a d subshell, and seven in an d subshell.

REPRESENTATIONS OF ORBITALS (SECTION 6.6) Contour representations are useful for visualizing the shapes of the orbitals. Represented this way, s orbitals appear as spheres that increase in size as n increases. The **radial probability function** tells us the probability that the electron will be found at a certain distance from the nucleus. The wave function for each p orbital has two lobes on opposite sides of the nucleus. They are oriented along the x, y, and z axes. Four of the d orbitals appear as shapes with four lobes around the nucleus; the fifth one, the d_z orbital, is represented as two lobes along the z axis and a "doughnut" in the xy plane. Regions in which the wave function is zero are called **nodes**. There is zero probability that the electron will be found at a node.

MANY-ELECTRON ATOMS (SECTION 6.7) In many-electron atoms, different subshells of the same electron shell have different energies. For a given value of n, the energy of the subshells increases as the value of l increases: ns < np < nd < nf. Orbitals within the same subshell are **degenerate**, meaning they have the same energy.

Electrons have an intrinsic property called **electron spin**, which is quantized. The **spin magnetic quantum number**, m_s , can have two possible values, $+\frac{1}{2}$ and $-\frac{1}{2}$, which can be envisioned as the two directions of an electron spinning about an axis. The **Pauli exclusion principle** states that no two electrons in an atom can have the same values for n, l, m_b and m_s . This

principle places a limit of two on the number of electrons that can occupy any one atomic orbital. These two electrons differ in their value of m_s .

ELECTRON CONFIGURATIONS AND THE PERIODIC TABLE (SECTIONS 6.8 AND 6.9) The electron configuration of an atom describes how the electrons are distributed among the orbitals of the atom. The ground-state electron configurations are generally obtained by placing the electrons in the atomic orbitals of lowest possible energy with the restriction that each orbital can hold no more than two electrons. We depict the arrangement of the electrons pictorially using an **orbital diagram**. When electrons occupy a subshell with more than one degenerate orbital, such as the 2p subshell, **Hund's rule** states that the lowest energy is attained by maximizing the number of electrons with the same electron spin. For example, in the ground-state electron configuration of carbon, the two 2p electrons have the same spin and must occupy two different 2p orbitals.

Elements in any given group in the periodic table have the same type of electron arrangements in their outermost shells. For example, the electron configurations of the halogens fluorine and chlorine are $[\text{He}]2s^22p^5$ and $[\text{Ne}]3s^23p^5$, respectively. The outer-shell electrons are those that lie outside the orbitals occupied in the next lowest noble-gas element. The outer-shell electrons that are involved in chemical bonding are the **valence electrons** of an atom; for the elements with atomic number 30 or less, all the outer-shell electrons are valence electrons. The electrons that are not valence electrons are called **core electrons**.

The periodic table is partitioned into different types of elements, based on their electron configurations. Those elements in which the outermost subshell is an *s* or *p* subshell are called the **representative** (or **main-group**) **elements**. The alkali metals (group 1A), halogens (group 7A), and noble gases (group 8A) are representative elements. Those elements in which a *d* subshell is being filled are called the **transition elements** (or **transition metals**). The elements in which the 4*f* subshell is being filled are called the **lanthanide** (or **rare earth**) **elements**. The actinide elements are those in which the 5*f* subshell is being filled. The lanthanide and **actinide elements** are collectively referred to as the *f*-block metals. These elements are shown as two rows of 14 elements below the main part of the periodic table. The structure of the periodic table, summarized in Figure 6.31, allows us to write the electron configuration of an element from its position in the periodic table.

Learning Outcomes After studying this chapter, you should be able to:

- Calculate the wavelength of electromagnetic radiation given its frequency or its frequency given its wavelength. (Section 6.1)
- Order the common kinds of radiation in the electromagnetic spectrum according to their wavelengths or energy. (Section 6.1)
- Explain what photons are and be able to calculate their energies given either their frequency or wavelength. (Section 6.2)
- Explain how line spectra relate to the idea of quantized energy states of electrons in atoms. (Section 6.3)
- Calculate the wavelength of a moving object. (Section 6.4)
- Explain how the uncertainty principle limits how precisely we can specify the position and the momentum of subatomic particles such as electrons. (Section 6.4)

- Relate the quantum numbers to the number and type of orbitals and recognize the different orbital shapes. (Section 6.5)
- Interpret radial probability function graphs for the orbitals. (Section 6.6)
- Explain how and why the energies of the orbitals are different in a many-electron atom from those in the hydrogen atom (Section 6.7)
- Draw an energy-level diagram for the orbitals in a many-electron atom and describe how electrons populate the orbitals in the ground state of an atom, using the Pauli exclusion principle and Hund's rule. (Section 6.8)
- Use the periodic table to write condensed electron configurations and determine the number of unpaired electrons in an atom. (Section 6.9)

Key Equations

• $\lambda \nu = c$

[6.1] light as a wave: $\lambda = \text{wavelength in meters}, \nu = \text{frequency in s}^{-1},$ $c = \text{speed of light } (2.998 \times 10^8 \,\text{m/s})$

• $E = h\nu$

6.2] light as a particle (photon): E = energy of photon in joules, h = Planck constant(6.626 × 10⁻³⁴ J-s), $\nu = \text{frequency in s}^{-1}$ (same frequency as previous formula) energies of the allowed states of the hydrogen atom: h = Planck constant; c = speed of light; $R_{\text{H}} = \text{Rydberg constant}$ $(1.096776 \times 10^7 \,\text{m}^{-1}); n = 1, 2, 3, \dots$ (any positive integer)

• $\lambda = h/mv$

[6.8] matter as a wave: $\lambda = \text{wavelength}$, h = Planck constant, m = mass of object in kg, v = speed of object in m/s

• $\Delta x \cdot \Delta(mv) \ge \frac{h}{4\pi}$

Heisenberg's uncertainty principle. The uncertainty in position (Δx) and momentum $[\Delta(mv)]$ of an object cannot be zero; the smallest value of their product is $h/4\pi$

Exercises

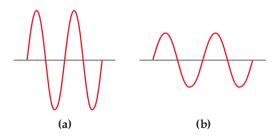

Visualizing Concepts

6.1 Consider the water wave shown here. (a) How could you measure the speed of this wave? (b) How would you determine the wavelength of the wave? (c) Given the speed and wavelength of the wave, how could you determine the frequency of the wave? (d) Suggest an independent experiment to determine the frequency of the wave. [Section 6.1]

[6.9]

- 6.2 A popular kitchen appliance produces electromagnetic radiation with a frequency of 2450 MHz. With reference to Figure 6.4, answer the following: (a) Estimate the wavelength of this radiation. (b) Would the radiation produced by the appliance be visible to the human eye? (c) If the radiation is not visible, do photons of this radiation have more or less energy than photons of visible light? (d) Which of the following is the appliance likely to be? (i) A toaster oven, (ii) A microwave oven, or (iii) An electric hotplate. [Section 6.1]
- **6.3** The following diagrams represent two electromagnetic waves. Which wave corresponds to the higher-energy radiation? [Section 6.2]

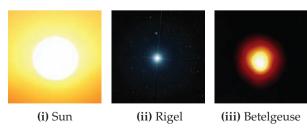

6.4 As shown in the accompanying photograph, an electric stove burner on its highest setting exhibits an orange glow.(a) When the burner setting is changed to low, the burner continues to produce heat but the orange glow disappears. How can

this observation be explained with reference to one of the fundamental observations that led to the notion of quanta? (b) Suppose that the energy provided to the burner could be increased beyond the highest setting of the stove. What would we expect to observe with regard to visible light emitted by the burner? [Section 6.2]

6.5 Stars do not all have the same temperature. The color of light emitted by stars is characteristic of the light emitted by hot objects. Telescopic photos of three stars are shown below:

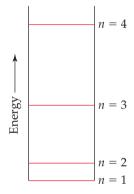

(i) the Sun, which is classified as a *yellow* star, (ii) *Rigel*, in the constellation Orion, which is classified as a *blue-white* star, and
(iii) *Betelgeuse*, also in Orion, which is classified as a *red* star.
(a) Place these three stars in order of increasing temperature.
(b) Which of the following principles is relevant to your choice of answer for part (a): The uncertainty principle, the photoelectric effect, blackbody radiation, or line spectra? [Section 6.2]

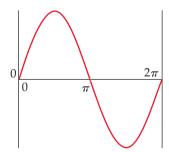

6.6 The familiar phenomenon of a rainbow results from the diffraction of sunlight through raindrops. (a) Does the wavelength of light increase or decrease as we proceed outward from the innermost band of the rainbow? (b) Does the frequency of light increase or decrease as we proceed outward? (c) Suppose that instead of sunlight, the visible light from a hydrogen discharge tube (Figure 6.10) was used as the light source. What do you think the resulting "hydrogen discharge rainbow" would look like? [Section 6.3]

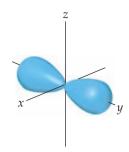

6.7 A certain quantum mechanical system has the energy levels shown in the accompanying diagram. The energy levels are indexed by a single quantum number n that is an integer. (a) As drawn, which quantum numbers are involved in the transition that requires the most energy? (b) Which quantum numbers are involved in the transition that requires the least energy? (c) Based on the drawing, put the following in order of increasing wavelength of the light absorbed or emitted during the transition: (i) n = 1 to n = 2; (ii) n = 3 to n = 2; (iii) n = 2 to n = 4; (iv) n = 3 to n = 1. [Section 6.3]

6.8 Consider a fictitious one-dimensional system with one electron. The wave function for the electron, drawn below, is $\psi(x) = \sin x$ from x = 0 to $x = 2\pi$. (a) Sketch the probability density, $\psi^2(x)$, from x = 0 to $x = 2\pi$. (b) At what value or values of x will there be the greatest probability of finding the electron? (c) What is the probability that the electron will be found at $x = \pi$? What is such a point in a wave function called? [Section 6.5]

6.9 The contour representation of one of the orbitals for the n=3 shell of a hydrogen atom is shown as follows. (a) What is the quantum number l for this orbital? (b) How do we label this orbital? (c) In which of the following ways would you modify this sketch to show the analogous orbital for the n=4 shell: (i) It doesn't change, (ii) it would be drawn larger, (iii) another lobe would be added along the +x axis, or (iv) the lobe on the +y axis would be larger than the lobe on the -y axis? [Section 6.6]

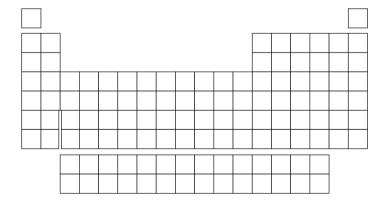

6.10 The accompanying drawing shows the shape of a *d* orbital.
(a) Based on the shape, how many of the *d* orbitals could it be?
(b) Which of the following would you need to determine which of the *d* orbitals it is: (i) the direction of the *z*-axis, (ii) the identity of the element, (iii) the number of electrons in the orbital, or (iv) the directions of two of the major axes? [Section 6.6]

6.11 The accompanying drawing shows part of the orbital diagram for an element. (a) As drawn, the drawing is *incorrect*. Why?(b) How would you correct the drawing without changing the number of electrons? (c) To which group in the periodic table does the element belong? [Section 6.8]

11	1	1

- **6.12** State where in the periodic table these elements appear:
 - (a) elements with the valence-shell electron configuration ns^2np^5
 - **(b)** elements that have three unpaired *p* electrons
 - (c) an element whose valence electrons are $4s^24p^1$
 - (d) the *d*-block elements [Section 6.9]

The Wave Nature of Light (Section 6.1)

- **6.13** What are the basic SI units for (a) the wavelength of light, (b) the frequency of light, (c) the speed of light?
- **6.14** (a) What is the relationship between the wavelength and the frequency of radiant energy? (b) Ozone in the upper atmosphere absorbs energy in the 210–230-nm range of the spectrum. In what region of the electromagnetic spectrum does this radiation occur?

- 6.15 Label each of the following statements as true or false. For those that are false, correct the statement. (a) Visible light is a form of electromagnetic radiation. (b) Ultraviolet light has longer wavelengths than visible light. (c) X rays travel faster than microwaves. (d) Electromagnetic radiation and sound waves travel at the same speed.
- 6.16 Determine which of the following statements are false and correct them. (a) The frequency of radiation increases as the wavelength increases. (b) Electromagnetic radiation travels through a vacuum at a constant speed, regardless of wavelength. (c) Infrared light has higher frequencies than visible light. (d) The glow from a fireplace, the energy within a microwave oven, and a foghorn blast are all forms of electromagnetic radiation.
- **6.17** Arrange the following kinds of electromagnetic radiation in order of increasing wavelength: infrared, green light, red light, radio waves, X rays, ultraviolet light.
- 6.18 List the following types of electromagnetic radiation in order of increasing wavelength: (a) the gamma rays produced by a radioactive nuclide used in medical imaging; (b) radiation from an FM radio station at 93.1 MHz on the dial; (c) a radio signal from an AM radio station at 680 kHz on the dial; (d) the yellow light from sodium vapor streetlights; (e) the red light of a light-emitting diode, such as in a calculator display.
- **6.19** (a) What is the frequency of radiation that has a wavelength of $10 \,\mu\text{m}$, about the size of a bacterium? (b) What is the wavelength of radiation that has a frequency of $5.50 \times 10^{14} \, \text{s}^{-1}$? (c) Would the radiations in part (a) or part (b) be visible to the human eye? (d) What distance does electromagnetic radiation travel in $50.0 \,\mu\text{s}$?
- **6.20** (a) What is the frequency of radiation whose wavelength is 0.86 nm? (b) What is the wavelength of radiation that has a frequency of $6.4 \times 10^{11} \, \text{s}^{-1}$? (c) Would the radiations in part (a) or part (b) be detected by an X-ray detector? (d) What distance does electromagnetic radiation travel in 0.38 ps?
- **6.21** A laser pointer used in a lecture hall emits light at 650 nm. What is the frequency of this radiation? Using Figure 6.4, predict the color associated with this wavelength.
- **6.22** It is possible to convert radiant energy into electrical energy using photovoltaic cells. Assuming equal efficiency of conversion, would infrared or ultraviolet radiation yield more electrical energy on a per-photon basis?

Quantized Energy and Photons (Section 6.2)

- 6.23 If human height were quantized in 1-foot increments, what would happen to the height of a child as she grows up: (i) The child's height would never change, (ii) the child's height would continuously get greater, (iii) the child's height would increase in "jumps" of 1 foot at a time, or (iv) the child's height would increase in jumps of 6 in?
- 6.24 Einstein's 1905 paper on the photoelectric effect was the first important application of Planck's quantum hypothesis. Describe Planck's original hypothesis, and explain how Einstein made use of it in his theory of the photoelectric effect.
- **6.25** (a) Calculate the energy of a photon of electromagnetic radiation whose frequency is $2.94 \times 10^{14} \, \text{s}^{-1}$. (b) Calculate the energy of a photon of radiation whose wavelength is 413 nm. (c) What wavelength of radiation has photons of energy $6.06 \times 10^{-19} \, \text{J}$?
- **6.26** (a) A green laser pointer emits light with a wavelength of 532 nm. What is the frequency of this light? (b) What is the

- energy of one of these photons? (c) The laser pointer emits light because electrons in the material are excited (by a battery) from their ground state to an upper excited state. When the electrons return to the ground state, they lose the excess energy in the form of 532-nm photons. What is the energy gap between the ground state and excited state in the laser material?
- **6.27** (a) Calculate and compare the energy of a photon of wavelength 3.3 μ m with that of wavelength 0.154 nm. (b) Use Figure 6.4 to identify the region of the electromagnetic spectrum to which each belongs.
- 6.28 An AM radio station broadcasts at 1010 kHz, and its FM partner broadcasts at 98.3 MHz. Calculate and compare the energy of the photons emitted by these two radio stations.
- 6.29 One type of sunburn occurs on exposure to UV light of wavelength in the vicinity of 325 nm. (a) What is the energy of a photon of this wavelength? (b) What is the energy of a mole of these photons? (c) How many photons are in a 1.00 mJ burst of this radiation? (d) These UV photons can break chemical bonds in your skin to cause sunburn—a form of radiation damage. If the 325-nm radiation provides exactly the energy to break an average chemical bond in the skin, estimate the average energy of these bonds in kJ/mol.
- 6.30 The energy from radiation can be used to cause the rupture of chemical bonds. A minimum energy of 242 kJ/mol is required to break the chlorine-chlorine bond in Cl₂. What is the longest wavelength of radiation that possesses the necessary energy to break the bond? What type of electromagnetic radiation is this?
- **6.31** A diode laser emits at a wavelength of 987 nm. (a) In what portion of the electromagnetic spectrum is this radiation found? (b) All of its output energy is absorbed in a detector that measures a total energy of 0.52 J over a period of 32 s. How many photons per second are being emitted by the laser?
- **6.32** A stellar object is emitting radiation at 3.55 mm. (a) What type of electromagnetic spectrum is this radiation? (b) If a detector is capturing 3.2×10^8 photons per second at this wavelength, what is the total energy of the photons detected in 1.0 hour?
- **6.33** Molybdenum metal must absorb radiation with a minimum frequency of $1.09 \times 10^{15} \, \mathrm{s}^{-1}$ before it can eject an electron from its surface via the photoelectric effect. (a) What is the minimum energy needed to eject an electron? (b) What wavelength of radiation will provide a photon of this energy? (c) If molybdenum is irradiated with light of wavelength of 120 nm, what is the maximum possible kinetic energy of the emitted electrons?
- **6.34** Titanium metal requires a photon with a minimum energy of 6.94×10^{-19} J to emit electrons. (a) What is the minimum frequency of light necessary to emit electrons from titanium via the photoelectric effect? (b) What is the wavelength of this light? (c) Is it possible to eject electrons from titanium metal using visible light? (d) If titanium is irradiated with light of wavelength 233 nm, what is the maximum possible kinetic energy of the emitted electrons? (d) What is the maximum number of electrons that can be freed by a burst of light whose total energy is 2.00 μ J?

Bohr's Model; Matter Waves (Sections 6.3 and 6.4)

6.35 Explain how the existence of line spectra is consistent with Bohr's theory of quantized energies for the electron in the hydrogen atom.

- **6.36** (a) Consider the following three statements: (i) A hydrogen atom in the n=3 state can emit light at only two specific wavelengths, (ii) a hydrogen atom in the n=2 state is at a lower energy than the n=1 state, and (iii) the energy of an emitted photon equals the energy difference of the two states involved in the emission. Which of these statements is or are true? (b) Does a hydrogen atom "expand" or "contract" as it moves from its ground state to an excited state?
- 6.37 Is energy emitted or absorbed when the following electronic transitions occur in hydrogen? (a) from n = 4 to n = 2,
 (b) from an orbit of radius 2.12 Å to one of radius 8.46 Å,
 (c) an electron adds to the H⁺ ion and ends up in the n = 3 shell?
- **6.38** Indicate whether energy is emitted or absorbed when the following electronic transitions occur in hydrogen: (a) from n = 2 to n = 6, (b) from an orbit of radius 4.76 Å to one of radius 0.529 Å, (c) from the n = 6 to the n = 9 state.
- **6.39** (a) Using Equation 6.5, calculate the energy of an electron in the hydrogen atom when n = 2 and when n = 6. Calculate the wavelength of the radiation released when an electron moves from n = 6 to n = 2. (b) Is this line in the visible region of the electromagnetic spectrum? If so, what color is it?
- 6.40 Consider a transition of the electron in the hydrogen atom from n = 4 to n = 9. (a) Is ΔE for this process positive or negative?
 (b) Determine the wavelength of light that is associated with this transition. Will the light be absorbed or emitted? (c) In which portion of the electromagnetic spectrum is the light in part (b)?
- **6.41** The visible emission lines observed by Balmer all involved $n_{\rm f}=2$. (a) Which of the following is the best explanation of why the lines with $n_{\rm f}=3$ are not observed in the visible portion of the spectrum: (i) Transitions to $n_{\rm f}=3$ are not allowed to happen, (ii) transitions to $n_{\rm f}=3$ emit photons in the infrared portion of the spectrum, (iii) transitions to $n_{\rm f}=3$ emit photons in the ultraviolet portion of the spectrum, or (iv) transitions to $n_{\rm f}=3$ emit photons that are at exactly the same wavelengths as those to $n_{\rm f}=2$. (b) Calculate the wavelengths of the first three lines in the Balmer series—those for which $n_{\rm i}=3,4$, and 5—and identify these lines in the emission spectrum shown in Figure 6.11.
- **6.42** The Lyman series of emission lines of the hydrogen atom are those for which $n_{\rm f}=1$. (a) Determine the region of the electromagnetic spectrum in which the lines of the Lyman series are observed. (b) Calculate the wavelengths of the first three lines in the Lyman series—those for which $n_{\rm i}=2,3$, and 4.
- **6.43** One of the emission lines of the hydrogen atom has a wavelength of 93.07 nm. (a) In what region of the electromagnetic spectrum is this emission found? (b) Determine the initial and final values of *n* associated with this emission.
- **6.44** The hydrogen atom can absorb light of wavelength 1094 nm. (a) In what region of the electromagnetic spectrum is this absorption found? (b) Determine the initial and final values of *n* associated with this absorption.
- **6.45** Order the following transitions in the hydrogen atom from smallest to largest frequency of light absorbed: n = 3 to n = 6, n = 4 to n = 9, n = 2 to n = 3, and n = 1 to n = 2.
- **6.46** Place the following transitions of the hydrogen atom in order from shortest to longest wavelength of the photon emitted: n = 5 to n = 3, n = 4 to n = 2, n = 7 to n = 4, and n = 3 to n = 2.
- **6.47** Use the de Broglie relationship to determine the wavelengths of the following objects: (a) an 85-kg person skiing at 50 km/hr, (b) a 10.0-g bullet fired at 250 m/s, (c) a lithium atom moving at $2.5 \times 10^5 \text{ m/s}$, (d) an ozone (O₃) molecule in the upper atmosphere moving at 550 m/s.

- **6.48** Among the elementary subatomic particles of physics is the muon, which decays within a few nanoseconds after formation. The muon has a rest mass 206.8 times that of an electron. Calculate the de Broglie wavelength associated with a muon traveling at 8.85×10^5 cm/s.
- **6.49** Neutron diffraction is an important technique for determining the structures of molecules. Calculate the velocity of a neutron needed to achieve a wavelength of 1.25 Å. (Refer to the inside cover for the mass of the neutron.)
- **6.50** The electron microscope has been widely used to obtain highly magnified images of biological and other types of materials. When an electron is accelerated through a particular potential field, it attains a speed of $9.47 \times 10^6 \, \text{m/s}$. What is the characteristic wavelength of this electron? Is the wavelength comparable to the size of atoms?
- 6.51 Using Heisenberg's uncertainty principle, calculate the uncertainty in the position of (a) a 1.50-mg mosquito moving at a speed of 1.40 m/s if the speed is known to within ±0.01 m/s;
 (b) a proton moving at a speed of (5.00 ± 0.01) × 10⁴ m/s. (The mass of a proton is given in the table of fundamental constants in the inside cover of the text.)
- **6.52** Calculate the uncertainty in the position of (a) an electron moving at a speed of $(3.00 \pm 0.01) \times 10^5 \, \text{m/s}$, (b) a neutron moving at this same speed. (The masses of an electron and a neutron are given in the table of fundamental constants in the inside cover of the text.) (c) Based on your answers to parts (a) and (b), which can we know with greater precision, the position of the electron or of the neutron?

Quantum Mechanics and Atomic Orbitals (Sections 6.5 and 6.6)

- **6.53** (a) Why does the Bohr model of the hydrogen atom violate the uncertainty principle? (b) In what way is the description of the electron using a wave function consistent with de Broglie's hypothesis? (c) What is meant by the term *probability density*? Given the wave function, how do we find the probability density at a certain point in space?
- 6.54 (a) According to the Bohr model, an electron in the ground state of a hydrogen atom orbits the nucleus at a specific radius of 0.53 Å. In the quantum mechanical description of the hydrogen atom, the most probable distance of the electron from the nucleus is 0.53 Å. Why are these two statements different?
 (b) Why is the use of Schrödinger's wave equation to describe the location of a particle very different from the description obtained from classical physics? (c) In the quantum mechanical description of an electron, what is the physical significance of the square of the wave function, ψ²?
- **6.55** (a) For n = 4, what are the possible values of l? (b) For l = 2, what are the possible values of m_l ? (c) If m_l is 2, what are the possible values for l?
- **6.56** How many possible values for l and m_l are there when (a) n = 3, (b) n = 5?
- **6.57** Give the numerical values of *n* and *l* corresponding to each of the following orbital designations: (a) 3*p*, (b) 2*s*, (c) 4*f*, (d) 5*d*.
- **6.58** Give the values for n, l, and m_l for (a) each orbital in the 2p subshell, (b) each orbital in the 5d subshell.
- **6.59** A certain orbital of the hydrogen atom has n = 4 and l = 2. (a) What are the possible values of m_l for this orbital? (b) What are the possible values of m_s for the orbital?

- **6.60** A hydrogen atom orbital has n = 5 and $m_l = -2$. (a) What are the possible values of l for this orbital? (b) What are the possible values of m_c for the orbital?
- **6.61** Which of the following represent impossible combinations of *n* and *l*? (a) 1*p*, (b) 4*s*, (c) 5*f*, (d) 2*d*
- **6.62** For the table that follows, write which orbital goes with the quantum numbers. Don't worry about *x*, *y*, *z* subscripts. If the quantum numbers are not allowed, write "not allowed."

N	1	m_l	Orbital
2	1	-1	2p (example)
1	0	0	
3	-3	2	
3	2	-2	
2	0	-1	
0	0	0	
4	2	1	
5	3	0	

- **6.63** Sketch the shape and orientation of the following types of orbitals: (a) s, (b) p_z , (c) d_{xy} .
- **6.64** Sketch the shape and orientation of the following types of orbitals: (a) p_{xx} (b) d_{x^2} , (c) $d_{x^2-y^2}$.
- 6.65 (a) What are the similarities of and differences between the 1s and 2s orbitals of the hydrogen atom? (b) In what sense does a 2p orbital have directional character? Compare the "directional" characteristics of the px and dx²-y² orbitals. (That is, in what direction or region of space is the electron density concentrated?)
 (c) What can you say about the average distance from the nucleus of an electron in a 2s orbital as compared with a 3s orbital?
 (d) For the hydrogen atom, list the following orbitals in order of increasing energy (that is, most stable ones first): 4f, 6s, 3d, 1s, 2p.
- **6.66** (a) With reference to Figure 6.19, what is the relationship between the number of nodes in an s orbital and the value of the principal quantum number? (b) Identify the number of nodes; that is, identify places where the electron density is zero, in the $2p_x$ orbital; in the 3s orbital. (c) What information is obtained from the radial probability functions in Figure 6.19? (d) For the hydrogen atom, list the following orbitals in order of increasing energy: 3s, 2s, 2p, 5s, 4d.

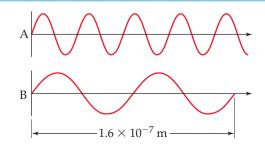

Many-Electron Atoms and Electron Configurations (Sections 6.7–6.9)

- **6.67** For a given value of the principal quantum number, *n*, how do the energies of the *s*, *p*, *d*, and *f* subshells vary for (a) hydrogen, (b) a many-electron atom?
- **6.68** (a) The average distance from the nucleus of a 3*s* electron in a chlorine atom is smaller than that for a 3*p* electron. In light

- of this fact, which orbital is higher in energy? (b) Would you expect it to require more or less energy to remove a 3s electron from the chlorine atom, as compared with a 2p electron?
- **6.69** (a) What experimental evidence is there for the electron having a "spin"? (b) Draw an energy-level diagram that shows the relative energetic positions of a 1s orbital and a 2s orbital. Put two electrons in the 1s orbital. (c) Draw an arrow showing the excitation of an electron from the 1s to the 2s orbital.
- 6.70 (a) State the Pauli exclusion principle in your own words.(b) The Pauli exclusion principle is, in an important sense, the key to understanding the periodic table. (c) Explain.
- **6.71** What is the maximum number of electrons that can occupy each of the following subshells? (a) 3*p*, (b) 5*d*, (c) 2*s*, (d) 4*f*.
- **6.72** What is the maximum number of electrons in an atom that can have the following quantum numbers? (a) n = 3, $m_l = -2$; (b) n = 4, l = 3; (c) n = 5, l = 3, $m_l = 2$, (d) n = 4, l = 1, $m_l = 0$.
- 6.73 (a) What are "valence electrons"? (b) What are "core electrons"? (c) What does each box in an orbital diagram represent?(d) What quantity is represented by the half arrows in an orbital diagram?
- **6.74** For each element, indicate the number of valence electrons, core electrons, and unpaired electrons in the ground state: (a) nitrogen, (b) silicon, (c) chlorine.
- **6.75** Write the condensed electron configurations for the following atoms, using the appropriate noble-gas core abbreviations: (a) Cs, (b) Ni, (c) Se, (d) Cd, (e) U, (f) Pb.
- **6.76** Write the condensed electron configurations for the following atoms and indicate how many unpaired electrons each has: (a) Mg, (b) Ge, (c) Br, (d) V, (e) Y, (f) Lu.
- **6.77** Identify the specific element that corresponds to each of the following electron configurations and indicate the number of unpaired electrons for each: (a) $1s^22s^2$, (b) $1s^22s^22p^4$, (c) $[Ar]4s^13d^5$, (d) $[Kr]5s^24d^{10}5p^4$.
- **6.78** Identify the group of elements that corresponds to each of the following generalized electron configurations and indicate the number of unpaired electrons for each:
 - (a) [noble gas] ns^2np^5
 - **(b)** [noble gas] $ns^2(n-1)d^2$
 - (c) [noble gas] $ns^2(n-1)d^{10}np^1$
 - (d) [noble gas] $ns^2(n-2)f^6$
- **6.79** What is wrong with the following electron configurations for atoms in their ground states? (a) $1s^22s^23s^1$, (b) [Ne] $2s^22p^3$, (c) [Ne] $3s^23d^5$.
- **6.80** The following electron configurations represent excited states. Identify the element and write its ground-state condensed electron configuration. (a) $1s^22s^22p^43s^1$, (b) $[Ar]4s^13d^{10}4p^25p^1$, (c) $[Kr]5s^24d^25p^1$.

Additional Exercises

- **6.81** Consider the two waves shown here, which we will consider to represent two electromagnetic radiations:
 - (a) What is the wavelength of wave A? Of wave B?
 - **(b)** What is the frequency of wave A? Of wave B?
 - (c) Identify the regions of the electromagnetic spectrum to which waves A and B belong.

- 6.82 If you put 120 volts of electricity through a pickle, the pickle will smoke and start glowing orange-yellow. The light is emitted because sodium ions in the pickle become excited; their return to the ground state results in light emission. (a) The wavelength of this emitted light is 589 nm. Calculate its frequency. (b) What is the energy of 0.10 mol of these photons? (c) Calculate the energy gap between the excited and ground states for the sodium ion. (d) If you soaked the pickle for a long time in a different salt solution, such as strontium chloride, would you still observe 589-nm light emission?
- **6.83** Certain elements emit light of a specific wavelength when they are burned. Historically, chemists used such emission wavelengths to determine whether specific elements were present in a sample. Characteristic wavelengths for some of the elements are given in the following table:

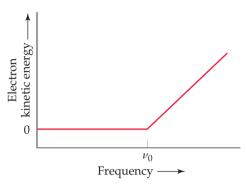

Ag	328.1 nm	Fe	372.0 nm
Au	267.6 nm	K	404.7 nm
Ba	455.4 nm	Mg	285.2 nm
Ca	422.7 nm	Na	589.6 nm
Cu	324.8 nm	Ni	341.5 nm

- (a) Determine which elements emit radiation in the visible part of the spectrum. (b) Which element emits photons of highest energy? Of lowest energy? (c) When burned, a sample of an unknown substance is found to emit light of frequency $9.23\times10^{14}\,\mathrm{s}^{-1}$. Which of these elements is probably in the sample?
- **6.84** In August 2011, the Juno spacecraft was launched from Earth with the mission of orbiting Jupiter in 2016. The closest distance between Jupiter and Earth is 391 million miles. (a) If it takes 5.0 years for Juno to reach Jupiter, what is its average speed in mi/hr over this period? (b) Once Juno reaches Jupiter, what is the minimum amount of time it takes for the transmitted signals to travel from the spacecraft to Earth?
- **6.85** The rays of the Sun that cause tanning and burning are in the ultraviolet portion of the electromagnetic spectrum. These rays are categorized by wavelength. So-called UV-A radiation has wavelengths in the range of 320–380 nm, whereas UV-B radiation has wavelengths in the range of 290–320 nm. (a) Calculate the frequency of light that has a wavelength of 320 nm. (b) Calculate the energy of a mole of 320-nm photons. (c) Which are more energetic, photons of UV-A radiation or photons of UV-B radiation? (d) The UV-B radiation from the Sun is considered a greater cause of sunburn in humans than is UV-A radiation. Is this observation consistent with your answer to part (c)?
- **6.86** The watt is the derived SI unit of power, the measure of energy per unit time: 1 W = 1 J/s. A semiconductor laser in a CD player has an output wavelength of 780 nm and a power level of 0.10 mW. How many photons strike the CD surface during the playing of a CD 69 minutes in length?
- 6.87 Carotenoids are yellow, orange, and red pigments synthesized by plants. The observed color of an object is not the color of light it absorbs but rather the complementary color, as described by a color wheel such as the one shown here. On this wheel, complementary colors are across from each other.

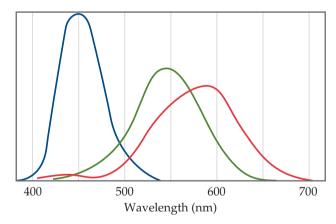

- (a) Based on this wheel, what color is absorbed most strongly if a plant is orange? (b) If a particular carotenoid absorbs photons at 455 nm, what is the energy of the photon?
- [6.88] In an experiment to study the photoelectric effect, a scientist measures the kinetic energy of ejected electrons as a function of

the frequency of radiation hitting a metal surface. She obtains the following plot. The point labeled " ν_0 " corresponds to light with a wavelength of 542 nm. (a) What is the value of ν_0 in s $^{-1}$? (b) What is the value of the work function of the metal in units of kJ/mol of ejected electrons? (c) Note that when the frequency of the light is greater than ν_0 , the plot shows a straight line with a nonzero slope. What is the slope of this line segment?

- [6.89] Consider a transition in which the hydrogen atom is excited from n = 1 to $n = \infty$. (a) What is the end result of this transition? (b) What is the wavelength of light that must be absorbed to accomplish this process? (c) What will occur if light with a shorter wavelength than that in part (b) is used to excite the hydrogen atom? (d) How the results of parts (b) and (c) related to the plot shown in Exercise 6.88?
- **6.90** The human retina has three types of receptor cones, each sensitive to a different range of wavelengths of visible light, as shown in this figure (the colors are merely to differentiate the three curves from one another; they do not indicate the actual colors represented by each curve):

- (a) Estimate the energies of photons with wavelengths at the maximum for each type of cone. (b) The color of the sky is due to scattering of solar light by the molecules of the atmosphere. Lord Rayleigh was one of the first to study scattering of this kind. He showed that the amount of scattering for very small particles such as molecules is inversely proportional to the fourth power of the wavelength. Estimate the ratio of the scattering efficiency of light at the wavelength of the maximum for the "blue" cones, as compared with that for the "green" cones. (c) Explain why the sky appears blue even though all wavelengths of solar light are scattered by the atmosphere.
- **6.91** The series of emission lines of the hydrogen atom for which $n_{\rm f}=3$ is called the *Paschen series*. (a) Determine the region of the electromagnetic spectrum in which the lines of the Paschen series are observed. (b) Calculate the wavelengths of the first three lines in the Paschen series—those for which $n_{\rm i}=4,5,$ and 6.

- 6.92 When the spectrum of light from the Sun is examined in high resolution in an experiment similar to that illustrated in Figure 6.9, dark lines are evident. These are called Fraunhofer lines, after the scientist who studied them extensively in the early nineteenth century. Altogether, about 25,000 lines have been identified in the solar spectrum between 2950 Å and 10,000 Å. The Fraunhofer lines are attributed to absorption of certain wavelengths of the Sun's "white" light by gaseous elements in the Sun's atmosphere.
 (a) Describe the process that causes absorption of specific wavelengths of light from the solar spectrum. (b) To determine which Fraunhofer lines belong to a given element, say, neon, what experiments could a scientist conduct here on Earth?
- 6.93 Determine whether each of the following sets of quantum numbers for the hydrogen atom are valid. If a set is not valid, indicate which of the quantum numbers has a value that is not valid:

(a)
$$n = 4, l = 1, m_l = 2, m_s = -\frac{1}{2}$$

(b)
$$n = 4, l = 3, m_l = -3, m_s = +\frac{1}{2}$$

(c)
$$n = 3, l = 2, m_l = -1, m_s = +\frac{1}{2}$$

(d)
$$n = 5, l = 0, m_l = 0, m_s = 0$$

(e)
$$n = 2, l = 2, m_l = 1, m_s = +\frac{1}{2}$$

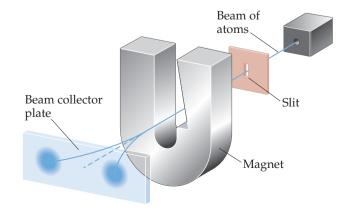

[6.94] Bohr's model can be used for hydrogen-like ions—ions that have only one electron, such as He⁺ and Li²⁺. (a) Why is the Bohr model applicable to He⁺ ions but not to neutral He atoms? (b) The ground-state energies of H, He⁺, and Li²⁺ are tabulated as follows:

Atom or ion H He⁺ Li²⁺ Ground-state $-2.18 \times 10^{-18} \text{ J} -8.72 \times 10^{-18} \text{ J} -1.96 \times 10^{-17} \text{ J}$ energy

By examining these numbers, propose a relationship between the ground-state energy of hydrogen-like systems and the nuclear charge, Z. (c) Use the relationship you derive in part (b) to predict the ground-state energy of the C^{5+} ion.

- **[6.95]** An electron is accelerated through an electric potential to a kinetic energy of 13.4 keV. What is its characteristic wavelength? [*Hint*: Recall that the kinetic energy of a moving object is $E = \frac{1}{2} mv^2$, where m is the mass of the object and ν is the speed of the object.]
- **6.96** In the television series *Star Trek*, the transporter beam is a device used to "beam down" people from the *Starship Enterprise* to another location, such as the surface of a planet. The writers of the show put a "Heisenberg compensator" into the transporter beam mechanism. Explain why such a compensator (which is entirely fictional) would be necessary to get around Heisenberg's uncertainty principle.
- [6.97] As discussed in the A Closer Look box on "Measurement and the Uncertainty Principle," the essence of the uncertainty principle is that we can't make a measurement without disturbing the system that we are measuring. (a) Why can't we measure the position of a subatomic particle without disturbing it? (b) How is this concept related to the paradox discussed in the Closer Look box on "Thought Experiments and Schrödinger's Cat"?
- [6.98] Consider the discussion of radial probability functions in "A Closer Look" in Section 6.6. (a) What is the difference between the probability density as a function of r and the radial probability function as a function of r? (b) What is the significance of the term $4\pi r^2$ in the radial probability functions for the s orbitals? (c) Based on Figures 6.19 and 6.22, make sketches of what you think the probability density as a

- function of *r* and the radial probability function would look like for the 4*s* orbital of the hydrogen atom.
- [6.99] For orbitals that are symmetric but not spherical, the contour representations (as in Figures 6.23 and 6.24) suggest where nodal planes exist (that is, where the electron density is zero). For example, the p_x orbital has a node wherever x = 0. This equation is satisfied by all points on the yz plane, so this plane is called a nodal plane of the p_x orbital. (a) Determine the nodal plane of the p_z orbital. (b) What are the two nodal planes of the $d_{x^2-y^2}$ orbital?
- [6.100] The Chemistry and Life box in Section 6.7 described the techniques called NMR and MRI. (a) Instruments for obtaining MRI data are typically labeled with a frequency, such as 600 MHz. Why do you suppose this label is relevant to the experiment? (b) What is the value of ΔE in Figure 6.27 that would correspond to the absorption of a photon of radiation with frequency 450 MHz? (c) In general, the stronger the magnetic field, the greater the information obtained from an NMR or MRI experiment. Why do you suppose this is the case?
- [6.101] Suppose that the spin quantum number, m_s , could have *three* allowed values instead of two. How would this affect the number of elements in the first four rows of the periodic table?
- **6.102** Using the periodic table as a guide, write the condensed electron configuration and determine the number of unpaired electrons for the ground state of (a) Br, (b) Ga, (c) Hf, (d) Sb, (e) Bi, (f) Sg.
- 6.103 Scientists have speculated that element 126 might have a moderate stability, allowing it to be synthesized and characterized. Predict what the condensed electron configuration of this element might be.
- [6.104] In the experiment shown schematically below, a beam of neutral atoms is passed through a magnetic field. Atoms that have unpaired electrons are deflected in different directions in the magnetic field depending on the value of the electron spin quantum number. In the experiment illustrated, we envision that a beam of hydrogen atoms splits into two beams. (a) What is the significance of the observation that the single beam splits into two beams? (b) What do you think would happen if the strength of the magnet were increased? (c) What do you think would happen if the beam of hydrogen atoms were replaced with a beam of helium atoms? Why? (d) The relevant experiment was first performed by Otto Stern and Walter Gerlach in 1921. They used a beam of Ag atoms in the experiment. By considering the electron configuration of a silver atom, explain why the single beam splits into two beams.

Integrative Exercises

6.105 Microwave ovens use microwave radiation to heat food. The energy of the microwaves is absorbed by water molecules in food and then transferred to other components of the food.

(a) Suppose that the microwave radiation has a wavelength of 11.2 cm. How many photons are required to heat 200 mL of coffee from 23 to 60 °C? (b) Suppose the microwave's power is 900 W (1 watt = 1 joule-second). How long would you have to heat the coffee in part (a)?

6.106 The stratospheric ozone (O_3) layer helps to protect us from harmful ultraviolet radiation. It does so by absorbing ultraviolet light and falling apart into an O_2 molecule and an oxygen atom, a process known as photodissociation.

$$O_3(g) \longrightarrow O_2(g) + O(g)$$

Use the data in Appendix C to calculate the enthalpy change for this reaction. What is the maximum wavelength a photon can have if it is to possess sufficient energy to cause this dissociation? In what portion of the spectrum does this wavelength occur?

6.107 The discovery of hafnium, element number 72, provided a controversial episode in chemistry. G. Urbain, a French chemist, claimed in 1911 to have isolated an element number 72 from a sample of rare earth (elements 58-71) compounds. However, Niels Bohr believed that hafnium was more likely to be found along with zirconium than with the rare earths. D. Coster and G. von Hevesy, working in Bohr's laboratory in Copenhagen, showed in 1922 that element 72 was present in a sample of Norwegian zircon, an ore of zirconium. (The name hafnium comes from the Latin name for Copenhagen, Hafnia). (a) How would you use electron configuration arguments to justify Bohr's prediction? (b) Zirconium, hafnium's neighbor in group 4B, can be produced as a metal by reduction of solid ZrCl₄ with molten sodium metal. Write a balanced chemical equation for the reaction. Is this an oxidation-reduction reaction? If yes, what is reduced and what is oxidized? (c) Solid zirconium dioxide, ZrO₂, reacts with chlorine gas in the presence of carbon. The products of the reaction are ZrCl₄ and two gases, CO₂ and CO in the ratio 1:2. Write a balanced chemical equation for the reaction. Starting with a 55.4-g sample of ZrO₂, calculate the mass of ZrCl₄ formed, assuming that ZrO2 is the limiting reagent and assuming 100% yield. (d) Using their electron configurations, account for the fact that Zr and Hf form chlorides MCl₄ and oxides MO₂. **6.108** (a) Account for formation of the following series of oxides in terms of the electron configurations of the elements and the discussion of ionic compounds in Section 2.7: K₂O, CaO, Sc₂O₃, TiO₂, V₂O₅, CrO₃. (b) Name these oxides. (c) Consider the metal oxides whose enthalpies of formation (in kJ mol⁻¹) are listed here.

Oxide	$K_2O(s)$	CaO(s)	$TiO_2(s)$	$V_2O_5(s)$
$\Delta H_{\!f}^{\circ}$	-363.2	-635.1	-938.7	-1550.6

Calculate the enthalpy changes in the following general reaction for each case:

$$M_nO_m(s) + H_2(g) \longrightarrow nM(s) + mH_2O(g)$$

(You will need to write the balanced equation for each case and then compute ΔH° .) (d) Based on the data given, estimate a value of ΔH_{f}° for $Sc_{2}O_{3}(s)$.

6.109 The first 25 years of the twentieth century were momentous for the rapid pace of change in scientists' understanding of the nature of matter. (a) How did Rutherford's experiments on the scattering of α particles by a gold foil set the stage for Bohr's theory of the hydrogen atom? (b) In what ways is de Broglie's hypothesis, as it applies to electrons, consistent with J. J. Thomson's conclusion that the electron has mass? In what sense is it consistent with proposals preceding Thomson's work that the cathode rays are a wave phenomenon?

6.110 The two most common isotopes of uranium are ²³⁵U and ²³⁸U. (a) Compare the number of protons, the number of electrons, and the number of neutrons in atoms of these two isotopes. (b) Using the periodic table in the front-inside cover, write the electron configuration for a U atom. (c) Compare your answer to part (b) to the electron configuration given in Figure 6.30. How can you explain any differences between these two electron configurations? (d) ²³⁸U undergoes radioactive decay to ²³⁴Th. How many protons, electrons, and neutrons are gained or lost by the ²³⁸U atom during this process? (e) Examine the electron configuration for Th in Figure 6.31. Are you surprised by what you find? Explain.

Design an Experiment

In this chapter, we have learned about the *photoelectric effect* and its impact on the formulation of light as photons. We have also seen that some anomalous electron configurations of the elements are particularly favorable if each atom has one or more half-filled shell, such as the case for the Cr atom with its $[Ar]4s^13d^5$ electron configuration. Let's suppose it is hypothesized that it requires more energy to remove an electron from a metal that has atoms with one or more half-filled shells than from those that do not. (a) Design a series of experiments involving the photoelectric effect that would test the hypothesis. (b) What experimental apparatus would be needed to test the hypothesis? It's not necessary that you name actual equipment but rather that you imagine how the apparatus would work—think in terms of the types of measurements that would be needed, and what capability you would need in your apparatus. (c) Describe the type of data you would collect and how you would analyze the data to see whether the hypothesis were correct. (d) Could your experiments be extended to test the hypothesis for other parts of the periodic table, such as the lanthanide or actinide elements?

Periodic Properties of the Elements

Why do some elements react more dramatically than others? If we drop a piece of gold metal into water, nothing happens. Dropping lithium metal into water initiates a slow reaction in which bubbles gradually form on the surface of the metal. By contrast, potassium metal reacts suddenly and violently with water, as shown here. Why do lithium and potassium react so differently with water, even though they are from the same family of the periodic table? To understand such differences we will examine how some key atomic properties change systematically as we traverse the periodic table.

As we saw in Chapter 6, the periodic nature of the periodic table arises from repeating patterns in the electron configurations of the elements. Elements in the same column contain the same number of electrons in their **valence orbitals**—the occupied orbitals that hold the electrons involved in bonding. For example, O ([He] $2s^22p^4$) and S ([Ne] $3s^23p^4$) are both in group 6A. The similarity of the electron distribution in their valence s and p orbitals leads to similarities in the properties of these two elements.

Electron configurations can be used to explain differences as well as similarities in the properties of elements. Despite similarities in their electron distributions, elemental oxygen and sulfur differ in fundamental ways. For example, at room temperature oxygen is a colorless gas but sulfur is a yellow solid. Might we explain these physical differences in noting that the outermost electrons of O are in the second shell, whereas those of S are in the third shell? We will see that even though elements share some similarities for being in the same *column* of the periodic table, there can be differences because elements are in different *rows* of the table.

► POTASSIUM METAL REACTING WITH WATER.

7.1 DEVELOPMENT OF THE PERIODIC TABLE

We begin our discussion with a brief history of the discovery of the periodic table.

7.2 EFFECTIVE NUCLEAR CHARGE We begin exploring many of the properties of atoms by examining the net attraction of the outer electrons to the nucleus and the average distance of those electrons from the nucleus. The net positive charge of the nucleus experienced by the outer electrons is called the *effective nuclear charge*.

- **7.3 SIZES OF ATOMS AND IONS** We explore the relative sizes of atoms and ions, both of which follow trends that are related to their placement in the periodic table and the trends in effective nuclear charge.
- **7.4 IONIZATION ENERGY** We next look at the trends in *ionization energy*, which is the energy required to remove one or more electrons from an atom. The periodic trends in ionization energy depend on variations in effective nuclear charge and atomic radii.
- **7.5 ELECTRON AFFINITY** Next we examine periodic trends in the *electron affinity*, the energy released when an electron is added to an atom.

7.6 METALS, NONMETALS, AND METALLOIDS

We learn that the physical and chemical properties of metals are different from those of nonmetals. These properties arise from the fundamental characteristics of atoms, particularly ionization energy. Metalloids display properties that are intermediate between those of metals and those of nonmetals.

7.7 TRENDS FOR GROUP 1A AND GROUP 2A METALS We examine some periodic trends in chemistry of group 1A and group 2A metals.

7.8 TRENDS FOR SELECTED NONMETALS Finally, we examine some of the periodic trends in the chemistry of hydrogen and the elements in groups 6A, 7A, and 8A.

In this chapter we explore how some of the important properties of elements change as we move across a row or down a column of the periodic table. In many cases the trends in a row or column allow us to predict the physical and chemical properties of elements.

7.1 | Development of the Periodic Table

The discovery of chemical elements has been ongoing since ancient times (**Figure 7.1**). Certain elements, such as gold (Au), appear in nature in elemental form and were thus discovered thousands of years ago. In contrast, some elements, such as technetium (Tc), are radioactive and intrinsically unstable. We know about them only because of technology developed during the twentieth century.

The majority of elements readily form compounds and, consequently, are not found in nature in their elemental form. For centuries, therefore, scientists were unaware of their existence. During the early nineteenth century, advances in chemistry made it easier to isolate elements from their compounds. As a result, the number of known elements more than doubled from 31 in 1800 to 63 by 1865.

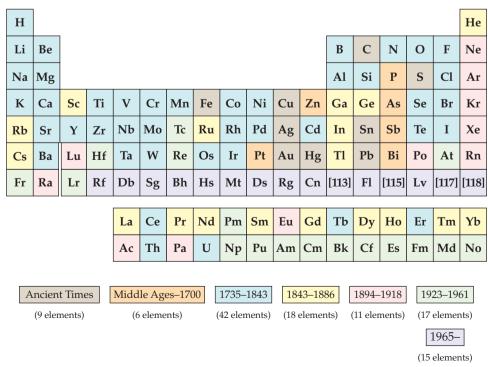

As the number of known elements increased, scientists began classifying them. In 1869, Dmitri Mendeleev in Russia and Lothar Meyer in Germany published nearly identical classification schemes. Both noted that similar chemical and physical properties recur periodically when the elements are arranged in order of increasing atomic weight. Scientists at that time had no knowledge of atomic numbers. Atomic weights, however, generally increase with increasing atomic number, so both Mendeleev and Meyer fortuitously arranged the elements in nearly the proper sequence.

Although Mendeleev and Meyer came to essentially the same conclusion about the periodicity of elemental properties, Mendeleev is given credit for advancing his ideas more vigorously and stimulating new work. His insistence that elements with similar

GO FIGURE

Copper, silver, and gold have all been known since ancient times, whereas most of the other metals have not. Can you suggest an explanation?

	Mendeleev's Predictions for	Observed Properties of Germanium
Property	Eka-Silicon (made in 1871)	(discovered in 1886)
Atomic weight	72	72.59
Density (g/cm³)	5.5	5.35
Specific heat (J/g-K)	0.305	0.309
Melting point (°C)	High	947

Table 7.1 Comparison of the Properties of Eka-Silicon Predicted by Mendeleev with the Observed Properties of Germanium

characteristics be listed in the same column forced him to leave blank spaces in his table. For example, both gallium (Ga) and germanium (Ge) were unknown to Mendeleev. He boldly predicted their existence and properties, referring to them as eka-aluminum ("under" aluminum) and eka-silicon ("under" silicon), respectively, after the elements under which they appeared in his table. When these elements were discovered, their properties closely matched those predicted by Mendeleev, as shown in \blacktriangle Table 7.1.

A little under 100

In 1913, two years after Rutherford proposed the nuclear model of the atom (Section 2.2), English physicist Henry Moseley (1887–1915) developed the concept of atomic numbers. Bombarding different elements with high-energy electrons, Moseley found that each element produced X rays of a unique frequency and that the frequency generally increased as the atomic mass increased. He arranged the X-ray frequencies in order by assigning a unique whole number, called an *atomic number*, to each element. Moseley correctly identified the atomic number as the number of protons in the nucleus of the atom. ∞ (Section 2.3)

The concept of atomic number clarified some problems in the periodic table of Moseley's day, which was based on atomic weights. For example, the atomic weight of Ar (atomic number 18) is greater than that of K (atomic number 19), yet the chemical and physical properties of Ar are much more like those of Ne and Kr than like those of Na and Rb. When the elements are arranged in order of increasing atomic number, Ar and K appear in their correct places in the table. Moseley's studies also made it possible to identify "holes" in the periodic table, which led to the discovery of new elements.

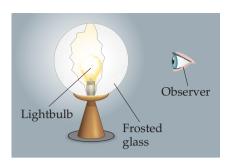

Give It Some Thought

Boiling point of chloride (°C)

Looking at the periodic table on the front inside cover, can you find an example other than Ar and K where the order of the elements would be different if the elements were arranged in order of increasing atomic weight?

7.2 | Effective Nuclear Charge

Many properties of atoms depend on electron configuration and on how strongly the outer electrons in the atoms are attracted to the nucleus. Coulomb's law tells us that the strength of the interaction between two electrical charges depends on the magnitudes of the charges and on the distance between them. (Section 2.3) Thus, the attractive force between an electron and the nucleus depends on the magnitude of the nuclear charge and on the average distance between the nucleus and the electron. The force increases as the nuclear charge increases and decreases as the electron moves farther from the nucleus.

▲ Figure 7.2 An analogy for effective nuclear charge. We envision the nucleus as a light bulb, and a valence electron an observer. The amount of light seen by the observer depends on the screening by the frosted glass lampshade.

Understanding the attraction between the electron and the nucleus in a hydrogen atom is straightforward because we have only one electron and one proton. In a many-electron atom, however, the situation is more complicated. In addition to the attraction of each electron to the nucleus, each electron experiences the repulsion due to other electrons. These electron–electron repulsions cancel some of the attraction of the electron to the nucleus so that the electron experiences less attraction than it would if the other electrons weren't there. In essence, each electron in a many-electron atom is *screened* from the nucleus by the other electrons. It therefore experiences a net attraction that is less than it would in the absence of other electrons.

How can we account for the combination of nuclear attraction and electron repulsions for our electron of interest? The simplest way to do so is to imagine that the electron experiences a net attraction that is the result of the nuclear attraction decreased by the electron–electron repulsions. We call this partially screened nuclear charge the **effective nuclear charge**, $Z_{\rm eff}$. Because the full attractive force of the nucleus has been decreased by the electron repulsions, we see that the effective nuclear charge is always less than the *actual* nuclear charge ($Z_{\rm eff} < Z$). We can define the amount of screening of the nuclear charge quantitatively by using a *screening constant*, S, such that

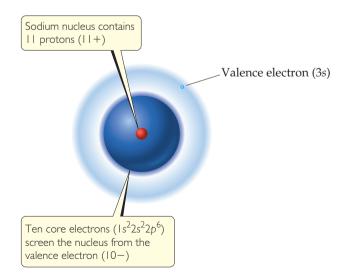

$$Z_{\text{eff}} = Z - S \tag{7.1}$$

where *S* is a positive number. For a valence electron, most of the shielding is due to the core electrons, which are much closer to the nucleus. As a result, for the valence electrons in an atom *the value of S is usually close to the number of core electrons in the atom*. (Electrons in the same valence shell do not screen one another very effectively, but they do affect the value of *S* slightly; see "A Closer Look: Effective Nuclear Charge.")

To understand better the notion of effective nuclear charge, we can use an analogy of a light bulb with a frosted glass shade (Figure 7.2). The light bulb represents the nucleus, and the observer is the electron of interest, which is usually a valence electron. The amount of light that the electron "sees" is analogous to the amount of net nuclear attraction experienced by the electron. The other electrons in the atom, especially the core electrons, act like a frosted glass lampshade, decreasing the amount of light that gets to the observer. If the light bulb gets brighter while the lampshade stays the same, more light is observed. Likewise, if the lampshade gets thicker, less light is observed. We will find it helpful to keep this analogy in mind as we discuss trends in effective nuclear charge.

Let's consider what we would expect for the magnitude of $Z_{\rm eff}$ for the sodium atom. Sodium has the electron configuration [Ne]3 s^1 . The nuclear charge is Z=11+, and there are 10 core electrons $(1s^22s^22p^6)$, which serve as a "lampshade" to screen the nuclear charge "seen" by the 3s electron. Therefore, in the simplest approach, we expect S to equal 10 and the 3s electron to experience an effective nuclear charge of $Z_{\rm eff}=11-10=1+$ (\P Figure 7.3). The situation is more complicated, however, because the 3s electron has a small probability of being closer to the nucleus, in the region occupied by the core electrons. (Section 6.6) Thus, this electron experiences a greater net attraction than our simple S=10 model suggests: The actual value of $Z_{\rm eff}$ for the 3s electron in Na is $Z_{\rm eff}=2.5+$. In other words, because there is a small probability that the 3s electron is close to the nucleus, the value of S in Equation 7.1 changes from 10 to 8.5.

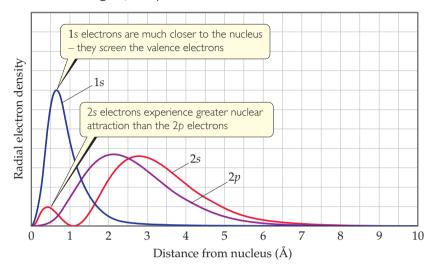

The notion of effective nuclear charge also explains an important effect we noted in Section 6.7: For a many-electron atom, the energies of orbitals with the same n value increase with increasing l value. For example, in the carbon atom, whose electron configuration is $1s^22s^22p^2$, the energy of the 2p orbital (l=1) is higher than that of the 2s orbital (l=0) even though both orbitals are in the n=2 shell (Figure 6.25). This difference in energies is due to

▲ Figure 7.3 Effective nuclear charge. The effective nuclear charge experienced by the 3s electron in a sodium atom depends on the 11+ charge of the nucleus and the 10- charge of the core electrons.

A GO FIGURE

Based on this figure, is it possible for an electron in a 2s orbital to be closer to the nucleus than an electron in a 1s orbital?

▲ Figure 7.4 Comparison of 1s, 2s, and 2p radial probability functions.

the radial probability functions for the orbitals (\triangle Figure 7.4). We see first that the 1s electrons are much closer to the nucleus—they serve as an effective "lampshade" for the 2s and 2p electrons. Notice next that the 2s probability function has a small peak fairly close to the nucleus, whereas the 2p probability function does not. As a result, a 2s electron is not screened as much by the core orbitals as is a 2p electron. The greater attraction between the 2s electron and the nucleus leads to a lower energy for the 2s orbital than for the 2p orbital. The same reasoning explains the general trend in orbital energies (ns < np < nd) in many-electron atoms.

Finally, let's examine trends in valence-electron Z_{eff} values. The effective nuclear charge increases from left to right across any period of the periodic table. Although the number of core electrons stays the same across the period, the number of protons increases—in our analogy, we are increasing the brightness of the lightbulb while keeping the shade the same. The valence electrons added to counterbalance the increasing nuclear charge screen one another ineffectively. Thus, Z_{eff} increases steadily. For example, the core electrons of lithium $(1s^22s^1)$ screen the 2s valence electron from the 3+ nucleus fairly efficiently. Consequently, the valence electron experiences an effective nuclear charge of roughly 3-2=1+. For beryllium $(1s^22s^2)$ the effective nuclear charge experienced by each valence electron is larger because here the 1s electrons screen a 4+ nucleus, and each 2s electron only partially screens the other. Consequently, the effective nuclear charge experienced by each 2s electron is about 4-2=2+.

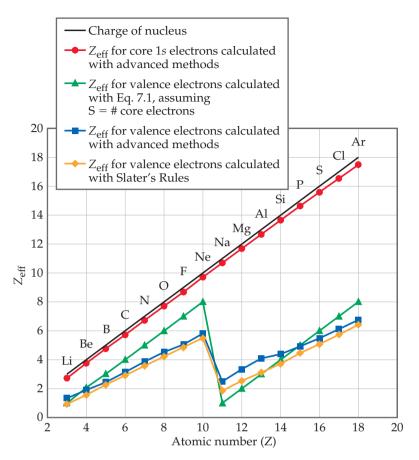

A Closer Look

Effective Nuclear Charge

To get a sense of how effective nuclear charge varies as both nuclear charge and number of electrons increase, consider Figure 7.5. Although the details of how the $Z_{\rm eff}$ values in the graph were calculated are beyond the scope of our discussion, the trends are instructive.

The effective nuclear charge felt by the outermost electrons is smaller than that felt by inner electrons because of screening by the inner electrons. In addition, the effective nuclear charge felt by the outermost electrons does not increase as steeply with increasing atomic number because the valence electrons make a small but nonnegligible contribution to the screening constant S. The most striking feature associated with the $Z_{\rm eff}$ value for the outermost electrons is the sharp drop between the last period 2 element (Ne) and the first period 3 element (Na). This drop reflects the fact that the core electrons are much more effective than the valence electrons at screening the nuclear charge.

Because Z_{eff} can be used to understand many physically measurable quantities, it is desirable to have a simple method for estimating it. The value of Z in Equation 7.1 is known exactly, so the

▲ Figure 7.5 Variations in effective nuclear charge for period 2 and period 3 elements. Moving from one element to the next in the periodic table, the increase in $Z_{\rm eff}$ felt by the innermost (1s) electrons (red circles) closely tracks the increase in nuclear charge Z (black line) because these electrons are not screened much. The results of several methods to calculate $Z_{\rm eff}$ for valence electrons are shown in other colors.

challenge boils down to estimating the value of S. In the text, we estimated S very simply by assuming that each core electron contributes 1.00 to S and the outer electrons contribute nothing. A more accurate approach was developed by John Slater, however, and we can use his approach if we limit ourselves to elements that do not have electrons in d or f subshells.

Electrons for which the principal quantum number n is larger than the value of n for the electron of interest contribute 0 to the value of s. Electrons with the same value of s as the electron of interest contribute 0.35 to the value of s. Electrons that have principal quantum number s contribute 0.85, while those with even smaller values of s contribute 1.00. For example, consider fluorine, which has the ground-state electron configuration s contribute 1.00 for example, consider fluorine, which has the ground-state electron configuration s contribute 1 state s considered in fluorine, Slater's rules tell us that s contribution of an electron to itself in screening; therefore, we consider only six s considered in screening; therefore, we consider only six s considered in screening. Thus, s considered in s considered

Values of $Z_{\rm eff}$ estimated using the simple method outlined in the text, as well as those estimated with Slater's rules, are plotted in Figure 7.5. While neither of these methods exactly replicate the values of $Z_{\rm eff}$ obtained from more sophisticated calculations, both methods effectively capture the periodic variation in $Z_{\rm eff}$. While Slater's approach is more accurate, the method outlined in the text does a reasonably good job of estimating $Z_{\rm eff}$ despite its simplicity. For our purposes, therefore, we can assume that the screening constant S in Equation 7.1 is roughly equal to the number of core electrons.

Related Exercises: 7.13, 7.14, 7.15, 7.16, 7.31, 7.32, 7.80, 7.81, 7.110

Going down a column, the effective nuclear charge experienced by valence electrons changes far less than it does across a period. For example, using our simple estimate for S we would expect the effective nuclear charge experienced by the valence electrons in lithium and sodium to be about the same, roughly 3-2=1+ for lithium and 11-10=1+ for sodium. In fact, however, effective nuclear charge increases slightly as we go down a column because the more diffuse core electron cloud is less able to screen the valence electrons from the nuclear charge. In the case of the alkali metals, $Z_{\rm eff}$ increases from 1.3+ for lithium, to 2.5+ for sodium, to 3.5+ for potassium.

Give It Some Thought

Which would you expect to experience a greater effective nuclear charge, a 2p electron of a Ne atom or a 3s electron of a Na atom?

7.3 | Sizes of Atoms and Ions

It is tempting to think of atoms as hard, spherical objects. According to the quantum mechanical model, however, atoms do not have sharply defined boundaries at which the electron distribution becomes zero. ∞ (Section 6.5) Nevertheless, we can define atomic size in several ways, based on the distances between atoms in various situations.

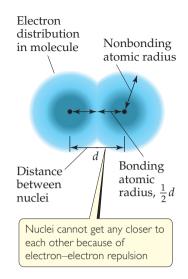

Imagine a collection of argon atoms in the gas phase. When two of these atoms collide, they ricochet apart like colliding billiard balls. This ricocheting happens because

the electron clouds of the colliding atoms cannot penetrate each other to any significant extent. The shortest distance separating the two nuclei during such collisions is twice the radii of the atoms. We call this radius the nonbonding atomic radius or the van der Waals radius (▶ Figure 7.6).

In molecules, the attractive interaction between any two adjacent atoms is what we recognize as a chemical bond. We discuss bonding in Chapters 8 and 9. For now, we need to realize that two bonded atoms are closer together than they would be in a nonbonding collision where the atoms ricochet apart. We can therefore define an atomic radius based on the distance between the nuclei when two atoms are bonded to each other, shown as distance *d* in Figure 7.6. The **bonding atomic radius** for any atom in a molecule is equal to half of the bond distance d. Note from Figure 7.6 that the bonding atomic radius (also known as the covalent radius) is smaller than the nonbonding atomic radius. Unless otherwise noted, we mean the bonding atomic radius when we speak of the "size" of an atom.

Scientists have developed a variety of techniques for measuring the distances separating nuclei in molecules. From observations of these distances in many molecules, each element can be assigned a bonding atomic radius. For example, in the I₂ molecule, the distance separating the nuclei is observed to be 2.66 Å, which means the bonding atomic radius of an iodine atom in I_2 is (2.66 Å)/2 = 1.33 Å.* Similarly, the distance separating adjacent carbon nuclei in diamond (a three-dimensional solid network of carbon atoms) is 1.54 Å; thus, the bonding atomic radius of carbon in diamond is 0.77 Å. By using structural information on more than 30,000 substances, a consistent set of bonding atomic radii of the elements can be defined (▼ Figure 7.7). Note that for helium and neon, the bonding atomic radii must be estimated because there are no known compounds of these elements.

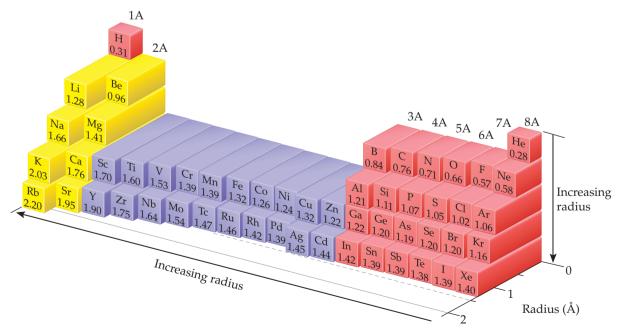

The atomic radii in Figure 7.7 allows us to estimate bond lengths in molecules. For example, the bonding atomic radii for C and Cl are 1.02 Å and 0.76 Å, respectively. In CCl₄ the measured length of the C—Cl bond is 1.77 Å, very close to the sum (1.02 + 0.76 Å) of the bonding atomic radii of Cl and C.

▲ Figure 7.6 Distinction between nonbonding and bonding atomic radii within a molecule.

GO FIGURE

Which part of the periodic table (top/bottom, left/right) has the elements with the largest atoms?

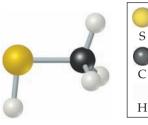

▲ Figure 7.7 Trends in bonding atomic radii for periods 1 through 5.

^{*}Remember: The angstrom (1 $\text{Å} = 10^{-10} \, \text{m}$) is a convenient metric unit for atomic measurements of length. It is not an SI unit. The most commonly used SI unit for atomic measurements is the picometer $(1 \text{ pm} = 10^{-12} \text{ m}; 1 \text{ Å} = 100 \text{ pm}).$

SAMPLE EXERCISE 7.1

Bond Lengths in a Molecule

Natural gas used in home heating and cooking is odorless. Because natural gas leaks pose the danger of explosion or suffocation, various smelly substances are added to the gas to allow detection of a leak. One such substance is methyl mercaptan, CH₃SH. Use Figure 7.7 to predict the lengths of the C—S, C—H, and S—H bonds in this molecule.

Methyl mercaptan

SOLUTION

Analyze and Plan We are given three bonds and told to use Figure 7.7 for bonding atomic radii. We will assume that each bond length is the sum of the bonding atomic radii of the two atoms involved.

Solve

C—S bond length = bonding atomic radius of C + bonding atomic radius of S
$$= 0.76 \, \mathring{A} + 1.05 \, \mathring{A} = 1.81 \, \mathring{A}$$
 C—H bond length = 0.76 $\mathring{A} + 0.31 \, \mathring{A} = 1.07 \, \mathring{A}$ S—H bond length = 1.05 $\mathring{A} + 0.31 \, \mathring{A} = 1.36 \, \mathring{A}$

Check The experimentally determined bond lengths are C - S = 1.82 Å, C - H = 1.10 Å, and S - H = 1.33 Å. (In general, the lengths of bonds involving hydrogen show larger deviations from the values predicted from bonding atomic radii than do bonds involving larger atoms.)

Comment Notice that our estimated bond lengths are close but not exact matches to the measured bond lengths. Bonding atomic radii must be used with some caution in estimating bond lengths.

Practice Exercise 1

Hypothetical elements X and Y form a molecule XY₂, in which both Y atoms are bonded to atom X (and not to one another). The X—X distance in the elemental form of X is 2.04 Å, and the Y—Y distance in elemental Y is 1.68 Å. What would you predict for the X—Y distance in the XY₂ molecule? (a) 0.84 Å (b) 1.02 Å (c) 1.86 Å (d) 2.70 Å (e) 3.72 Å

Practice Exercise 2

Using Figure 7.7, predict which is longer, the P— Br bond in PBr_3 or the As — Cl bond in $AsCl_3$.

Periodic Trends in Atomic Radii

Figure 7.7 shows two interesting trends:

- 1. Within each group, bonding atomic radius tends to increase from top to bottom. This trend results primarily from the increase in the principal quantum number (n) of the outer electrons. As we go down a column, the outer electrons have a greater probability of being farther from the nucleus, causing the atomic radius to increase.
- 2. Within each period, bonding atomic radius tends to decrease from left to right (although there are some minor exceptions, such as for Cl to Ar or As to Se). The major factor influencing this trend is the increase in effective nuclear charge $Z_{\rm eff}$ across a period. The increasing effective nuclear charge steadily draws the valence electrons closer to the nucleus, causing the bonding atomic radius to decrease.

Give It Some Thought

In Section 7.2 we said that $Z_{\rm eff}$ generally increases when you move down a column of the periodic table, whereas in Chapter 6 we saw that the "size" of an orbital increases as the principal quantum number n increases. With respect to atomic radii, do these trends work together or against each other? Which effect is larger?

SAMPLE EXERCISE 7.2 Predicting Relative Sizes of Atomic Radii

Referring to the periodic table, arrange (as much as possible) the atoms B, C, Al, and Si in order of increasing size.

SOLUTION

Analyze and Plan We are given the chemical symbols for four elements and told to use their relative positions in the periodic table to predict the relative size of their atomic radii. We can use the two periodic trends just described to help with this problem.

Solve C and B are in the same period, with C to the right of B. Therefore, we expect the radius of C to be smaller than that of B because radii usually decrease as we move across a period. Likewise, the radius of Si is expected to be smaller than that of Al. Al is directly below B, and Si is directly below C. We expect, therefore, the radius of B to be smaller than that of Al and the radius of C to be smaller than that of Si. Thus, so far we can say C < B, B < Al, C < Si, and Si < Al. We can therefore conclude that C has the smallest radius and Al has the largest radius, and so can write C < ? < ? < Al.

Our two periodic trends in atomic size do not supply enough information to allow us to determine, however, whether B or Si (represented by the two question marks) has the larger radius. Going from B to Si in the periodic table, we move down (radius tends to increase) and to the right (radius tends to decrease). It is only because Figure 7.7 provides numerical values for each atomic radius that we know that the radius of Si is greater than that of B. If you examine the figure carefully, you will discover that for the *s*- and *p*-block elements the increase

in radius moving down a column tends to be the greater effect. There are exceptions, however.

Check From Figure 7.7, we have

$$C(0.76 \text{ Å}) < B(0.84 \text{ Å}) < Si(1.11 \text{ Å}) < Al(1.21 \text{ Å}).$$

Comment Note that the trends we have just discussed are for the *s*- and *p*-block elements. Figure 7.7 shows that the transition elements do not show a regular decrease moving across a period.

Practice Exercise 1

By referring to the periodic table, but not to Figure 7.7, place the following atoms in order of increasing bonding atomic radius: N, O, P, Ge.

(a)
$$N < O < P < Ge$$

(b)
$$P < N < O < Ge$$

(c)
$$O < N < Ge < P$$

$$(\mathbf{d}) O < N < P < Ge$$

(e)
$$N < P < Ge < O$$

Practice Exercise 2

Arrange Be, C, K, and Ca in order of increasing atomic radius.

Periodic Trends in Ionic Radii

Just as bonding atomic radii can be determined from interatomic distances in molecules, ionic radii can be determined from interatomic distances in ionic compounds. Like the size of an atom, the size of an ion depends on its nuclear charge, the number of electrons it possesses, and the orbitals in which the valence electrons reside. When a cation is formed from a neutral atom, electrons are removed from the occupied atomic orbitals that are the most spatially extended from the nucleus. Also, when a cation is formed the number of electron–electron repulsions is reduced. Therefore, *cations are smaller than their parent atoms* (Figure 7.8). The opposite is true of anions. When electrons are added to an atom to form an anion, the increased electron–electron repulsions cause the electrons to spread out more in space. Thus, *anions are larger than their parent atoms*.

For ions carrying the same charge, ionic radius increases as we move down a column in the periodic table (Figure 7.8). In other words, as the principal quantum number of the outermost occupied orbital of an ion increases, the radius of the ion increases.

SAMPLE EXERCISE 7.3 Predicting Relative Sizes of Atomic and Ionic Radii

Arrange Mg²⁺, Ca²⁺, and Ca in order of decreasing radius.

SOLUTION

Cations are smaller than their parent atoms, and so $Ca^{2+} < Ca$. Because Ca is below Mg in group 2A, Ca^{2+} is larger than Mg^{2+} . Consequently, $Ca > Ca^{2+} > Mg^{2+}$.

Practice Exercise 1

Arrange the following atoms and ions in order of increasing ionic radius: F, S^{2-} , Cl, and Se^{2-} . (a) $F < S^{2-} < Cl < Se^{2-}$ (b) $F < Cl < S^{2-} < Se^{2-}$ (c) $F < S^{2-} < Se^{2-} < Cl$ (d) $Cl < F < Se^{2-} < S^{2-}$ (e) $S^{2-} < F < Se^{2-} < Cl$

Practice Exercise 2

Which of the following atoms and ions is largest: S^{2-} , S, O^{2-} ?

A GO FIGURE

How do cations of the same charge change in radius as you move down a column in the periodic table?

▲ Figure 7.8 Cation and anion size. Radii, in angstroms, of atoms and their ions for five groups of representative elements.

An isoelectronic series is a group of ions all containing the same number of electrons. For example, each ion in the isoelectronic series O²⁻, F⁻, Na⁺, Mg²⁺, and Al³⁺ has 10 electrons. In any isoelectronic series we can list the members in order of increasing atomic number; therefore, the nuclear charge increases as we move through the series. Because the number of electrons remains constant, ionic radius decreases with increasing nuclear charge as the electrons are more strongly attracted to the nucleus:

—Increasing nuclear charge
$$\longrightarrow$$
 O^{2-} F⁻ Na⁺ Mg²⁺ Al³⁺
1.26 Å 1.19 Å 1.16 Å 0.86 Å 0.68 Å

—Decreasing ionic radius \longrightarrow

Notice the positions and atomic numbers of these elements in the periodic table. The nonmetal anions precede the noble gas Ne in the table. The metal cations follow Ne. Oxygen, the largest ion in this isoelectronic series, has the lowest atomic number, 8. Aluminum, the smallest of these ions, has the highest atomic number, 13.

Chemistry Put to Work

Ionic Size and Lithium-Ion Batteries

Ionic size plays a major role in determining the properties of devices that rely on movement of ions. "Lithium-ion" batteries, which have become common energy sources for electronic devices such as cell phones, iPads, and laptop computers, rely in part on the small size of the lithium ion for their operation.

A fully charged battery spontaneously produces an electric current and, therefore, power when its positive and negative electrodes are connected to an electrical load, such as a device to be powered. The positive electrode is called the anode, and the negative electrode is called the cathode. The materials used for the electrodes in lithium-ion batteries are under intense development. Currently the anode material is graphite, a form of carbon, and the cathode is usually LiCoO₂, lithium cobalt oxide (▼ Figure 7.9). Between anode and cathode is a *separator*, a porous solid material that allows the passage of lithium ions but not electrons.

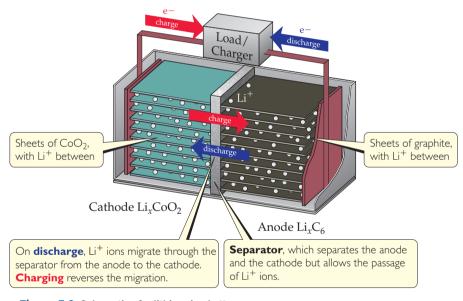

When the battery is being charged by an external source, lithium ions migrate through the separator from the cathode to the anode where they insert between the layers of carbon atoms. The ability of an ion to move through a solid increases as the size of the ion decreases and as the charge on the ion decreases. Lithium ions are smaller than most other cations, and they carry only a 1+ charge, which allows them to migrate more readily than other ions can. When the battery discharges, the lithium ions move from anode to cathode. To maintain charge balance, electrons simultaneously migrate from anode to cathode through an external circuit, thereby producing electricity.

At the cathode, lithium ions then insert in the oxide material. Again, the small size of lithium ions is an advantage. For every lithium ion that inserts into the lithium cobalt oxide cathode, a Co^{4+} ion is reduced to a Co^{3+} by an electron that has traveled through the external circuit.

The ion migration and the changes in structure that result when lithium ions enter and leave the electrode materials are complicated. Furthermore, the operation of all batteries generate heat because they are not perfectly efficient. In the case of Li-ion batteries, the heating of the separator material (typically a polymer) has led to problems as the size of the batteries has been scaled larger to increase energy capacity. In 2013, problems with overheating of large Li-ion batteries led to the temporary grounding of the new Boeing 787 Dreamliner aircraft.

Teams worldwide are trying to discover new cathode and anode materials that will easily accept and release lithium ions without falling apart over many repeated cycles. New separator materials that allow for faster passage of lithium ions with less heat generation are also under development. Some research groups are looking at using sodium ions instead of lithium ions because sodium is far more abundant than lithium, although the larger size of sodium ions poses additional challenges. In the next decade we expect great advances in battery technology based on alkali metal ions.

▲ Figure 7.9 Schematic of a lithium-ion battery.

SAMPLE EXERCISE 7.4 Ionic Radii in an Isoelectronic Series

Arrange the ions K⁺, Cl⁻, Ca²⁺, and S²⁻ in order of decreasing size.

SOLUTION

This is an isoelectronic series, with all ions having 18 electrons. In such a series, size decreases as nuclear charge (atomic number) increases. The atomic numbers of the ions are S 16, Cl 17, K 19, Ca 20. Thus, the ions decrease in size in the order $S^{2-} > Cl^- > K^+ > Ca^{2+}$.

Practice Exercise 1

Arrange the following atoms and ions in order of increasing ionic radius: Br^- , Rb^+ , Se^{2-} , Sr^{2+} , Te^{2-} .

(a)
$$Sr^{2+} < Rb^+ < Br^- < Se^{2-} < Te^{2-}$$

(b)
$$Br^- < Sr^{2+} < Se^{2-} < Te^{2-} < Rb^+$$

(c)
$$Rb^+ < Sr^{2+} < Se^{2-} < Te^{2-} < Br^{-}$$

(d)
$$Rb^+ < Br^- < Sr^{2+} < Se^{2-} < Te^{2-}$$

(e)
$$Sr^{2+} < Rb^{+} < Br^{-} < Te^{2-} < Se^{2-}$$

Practice Exercise 2

In the isoelectronic series Ca²⁺, Cs⁺, Y³⁺, which ion is largest?

7.4 | Ionization Energy

The ease with which electrons can be removed from an atom or ion has a major impact on chemical behavior. The **ionization energy** of an atom or ion is the minimum energy required to remove an electron from the ground state of the isolated gaseous atom or ion. We first encountered ionization in our discussion of the Bohr model of the hydrogen atom. ∞ (Section 6.3) If the electron in an H atom is excited from n = 1 (the ground state) to $n = \infty$, the electron is completely removed from the atom; the atom is *ionized*.

In general, the *first ionization energy*, I_1 , is the energy needed to remove the first electron from a neutral atom. For example, the first ionization energy for the sodium atom is the energy required for the process

$$Na(g) \longrightarrow Na^+(g) + e^-$$
 [7.2]

The *second ionization energy,* I_2 , is the energy needed to remove the second electron, and so forth, for successive removals of additional electrons. Thus, I_2 for the sodium atom is the energy associated with the process

$$Na^+(g) \longrightarrow Na^{2+}(g) + e^-$$
 [7.3]

Variations in Successive Ionization Energies

The magnitude of the ionization energy tells us how much energy is required to remove an electron; the greater the ionization energy, the more difficult it is to remove an electron. Notice in \blacktriangledown Table 7.2 that ionization energies for a given element increase as successive electrons are removed: $I_1 < I_2 < I_3$, and so forth. This trend makes sense because with each successive removal, an electron is being pulled away from an increasingly more positive ion, requiring increasingly more energy.

Give It Some Thought

Light can be used to ionize atoms and ions. Which of the two processes shown in Equations 7.2 and 7.3 requires shorter-wavelength radiation?

A second important feature shown in Table 7.2 is the sharp increase in ionization energy that occurs when an inner-shell electron is removed. For example, consider silicon, $1s^22s^22p^63s^23p^2$. The ionization energies increase steadily from 786 to $4356 \, \text{kJ/mol}$ for the four electrons in the 3s and 3p subshells. Removal of the fifth electron, which comes from the 2p subshell, requires a great deal more energy: $16,091 \, \text{kJ/mol}$. The large increase occurs because the 2p electron is much more likely to be found close to the nucleus than are the four n=3 electrons, and, therefore, the 2p electron experiences a much greater effective nuclear charge than do the 3s and 3p electrons.

able 7.2 Successive Values of Ionization Energies, I, for the Elements Sodium through Argon (kJ/mol)											
Element	I ₁	I ₂	I ₃	I_4	I ₅	I ₆	I ₇				
Na	496	4562			(inner-shell electr	rons)					
Mg	738	1451	7733								
Al	578	1817	2745	11,577

Table 7.2 Successive Values of Ionization Energies, I, for the Elements Sodium through Argon (kI/mol)

Give It Some Thought

Which would you expect to be greater, I_1 for a boron atom or I_2 for a carbon atom?

Every element exhibits a large increase in ionization energy when the first of its inner-shell electrons is removed. This observation supports the idea that only the outermost electrons are involved in the sharing and transfer of electrons that give rise to chemical bonding and reactions. As we will see when we talk about chemical bonds in Chapters 8 and 9, the inner electrons are too tightly bound to the nucleus to be lost from the atom or even shared with another atom.

SAMPLE EXERCISE 7.5 Trends in Ionization Energy

Three elements are indicated in the periodic table in the margin. Which one has the largest second ionization energy?

SOLUTION

Analyze and Plan The locations of the elements in the periodic table allow us to predict the electron configurations. The greatest ionization energies involve removal of core electrons. Thus, we should look first for an element with only one electron in the outermost occupied shell.

Solve The red box represents Na, which has one valence electron. The second ionization energy of this element is associated, therefore, with the removal of a core electron. The other elements indicated, S (green) and Ca (blue), have two or more valence electrons. Thus, Na should have the largest second ionization energy.

Check A chemistry handbook gives these I_2 values: Ca, 1145 kJ/mol; S, 2252 kJ/mol; Na, 4562 kJ/mol.

The third ionization energy of bromine is the energy required for which of the following processes? (a) $Br(g) \longrightarrow Br^+(g) + e^-$ (b) $Br^+(g) \longrightarrow Br^{2+}(g) + e^-$ (c) $Br(g) \longrightarrow Br^{2+}(g) + 2e^-$ (d) $Br(g) \longrightarrow Br^{3+}(g) + 3e^-$ (e) $Br^{2+}(g) \longrightarrow Br^{3+}(g) + e^-$

Practice Exercise 2

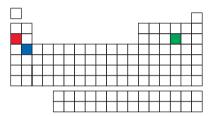

Which has the greater third ionization energy, Ca or S?

Periodic Trends in First Ionization Energies

Figure 7.10 shows, for the first 54 elements, the trends we observe in first ionization energies as we move from one element to another in the periodic table. The important trends are as follows:

- 1. I_1 generally increases as we move across a period. The alkali metals show the lowest ionization energy in each period, and the noble gases show the highest. There are slight irregularities in this trend that we will discuss shortly.
- **2.** I_1 generally decreases as we move down any column in the periodic table. For example, the ionization energies of the noble gases follow the order He > Ne > Ar > Kr > Xe.
- 3. The s- and p-block elements show a larger range of I_1 values than do the transition-metal elements. Generally, the ionization energies of the transition metals increase slowly from left to right in a period. The f-block metals (not shown in Figure 7.10) also show only a small variation in the values of I_1 .

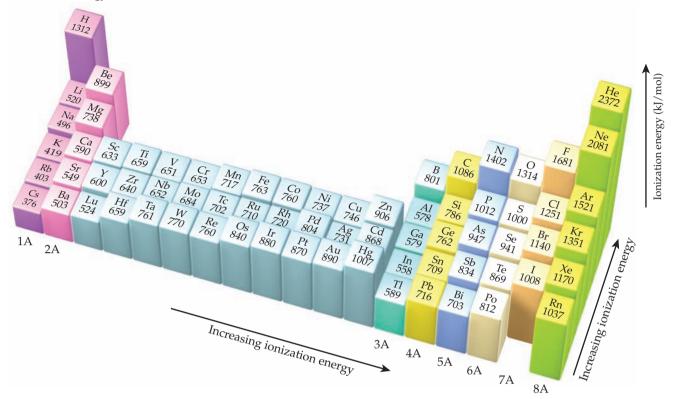

In general, smaller atoms have higher ionization energies. The same factors that influence atomic size also influence ionization energies. The energy needed to remove an electron from the outermost occupied shell depends on both the effective nuclear charge and the average distance of the electron from the nucleus. Either increasing the effective nuclear charge or decreasing the distance from the nucleus increases the attraction between the electron and the nucleus. As this attraction increases, it becomes more difficult to remove the electron, and, thus, the ionization energy increases.

GO FIGURE

The value for a tatine, At, is missing in this figure. To the nearest 100 kJ/mol, what estimate would you make for the first ionization energy of At?

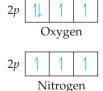

▲ Figure 7.10 Trends in first ionization energies of the elements.

GO FIGURE

Why is it easier to remove a 2*p* electron from an oxygen atom than from a nitrogen atom?

▲ Figure 7.11 2*p* orbital filling in nitrogen and oxygen.

As we move across a period, there is both an increase in effective nuclear charge and a decrease in atomic radius, causing the ionization energy to increase. As we move down a column, the atomic radius increases while the effective nuclear charge increases only gradually. The increase in radius dominates, so the attraction between the nucleus and the electron decreases, causing the ionization energy to decrease.

The irregularities in a given period are subtle but still readily explained. For example, the decrease in ionization energy from beryllium ($[He]2s^2$) to boron ($[He]2s^22p^1$), shown in Figure 7.10, occurs because the third valence electron of B must occupy the 2p subshell, which is empty for Be. Recall that the 2p subshell is at a higher energy than the 2s subshell (Figure 6.25). The slight decrease in ionization energy when moving from nitrogen ($[He]2s^22p^3$) to oxygen ($[He]2s^22p^4$) is the result of the repulsion of paired electrons in the p^4 configuration (\P Figure 7.11). Remember that according to Hund's rule, each electron in the p^3 configuration resides in a different p orbital, which minimizes the electron–electron repulsion among the three 2p electrons. ∞ (Section 6.8)

SAMPLE EXERCISE 7.6

Periodic Trends in Ionization Energy

Referring to the periodic table, arrange the atoms Ne, Na, P, Ar, K in order of increasing first ionization energy.

SOLUTION

Analyze and Plan We are given the chemical symbols for five elements. To rank them according to increasing first ionization energy, we need to locate each element in the periodic table. We can then use their relative positions and the trends in first ionization energies to predict their order.

Solve Ionization energy increases as we move left to right across a period and decreases as we move down a group. Because Na, P, and Ar are in the same period, we expect I_1 to vary in the order Na < P < Ar.

Because Ne is above Ar in group 8A, we expect Ar < Ne. Similarly, K is directly below Na in group 1A, and so we expect K < Na.

From these observations, we conclude that the ionization energies follow the order

Check The values shown in Figure 7.10 confirm this prediction.

Practice Exercise 1

Consider the following statements about first ionization energies:

- (i) Because the effective nuclear charge for Mg is greater than that for Be, the first ionization energy of Mg is greater than that of Be.
- (ii) The first ionization energy of O is less than that of N because in O we must pair electrons in the 2*p* orbitals.
- (iii) The first ionization energy of Ar is less than that of Ne because a 3p electron in Ar is farther from the nucleus than a 2p electron in Ne.

Which of the statements (i), (ii), and (iii) is or are true?

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

Practice Exercise 2

Which has the lowest first ionization energy, B, Al, C, or Si? Which has the highest?

Electron Configurations of Ions

When electrons are removed from an atom to form a cation, they are always removed first from the occupied orbitals having the largest principal quantum number, n. For example, when one electron is removed from a lithium atom $(1s^22s^1)$, it is the $2s^1$ electron:

$$Li(1s^22s^1) \Rightarrow Li^+(1s^2) + e^-$$

Likewise, when two electrons are removed from Fe ($[Ar]4s^23d^6$), the $4s^2$ electrons are the ones removed:

$$Fe(\lceil Ar \rceil 4s^2 3d^6) \Rightarrow Fe^{2+}(\lceil Ar \rceil 3d^6) + 2e^{-1}$$

If an additional electron is removed, forming Fe^{3+} , it comes from a 3*d* orbital because all the orbitals with n = 4 are empty:

$$Fe^{2+}([Ar]3d^6) \Rightarrow Fe^{3+}([Ar]3d^5) + e^{-}$$

It may seem odd that 4s electrons are removed before 3d electrons in forming transition-metal cations. After all, in writing electron configurations, we added the 4s electrons before the 3d ones. In writing electron configurations for atoms, however, we are going through an imaginary process in which we move through the periodic table from one element to another. In doing so, we are adding both an electron to an orbital and a proton to the nucleus to change the identity of the element. In ionization, we do not reverse this process because no protons are being removed.

If there is more than one occupied subshell for a given value of n, the electrons are first removed from the orbital with the highest value of l. For example, a tin atom loses its 5p electrons before it loses its 5s electrons:

$$Sn([Kr]5s^24d^{10}5p^2) \Rightarrow Sn^{2+}([Kr]5s^24d^{10}) + 2e^- \Rightarrow Sn^{4+}([Kr]4d^{10}) + 4e^-$$

Electrons added to an atom to form an anion are added to the empty or partially filled orbital having the lowest value of n. For example, an electron added to a fluorine atom to form the F ion goes into the one remaining vacancy in the 2p subshell:

$$F(1s^22s^22p^5) + e^- \Rightarrow F^-(1s^22s^22p^6)$$

Give It Some Thought

Do Cr^{3+} and V^{2+} have the same or different electron configurations?

SAMPLE EXERCISE 7.7 Electron Configurations of Ions

Write the electron configurations for (a) Ca^{2+} , (b) Co^{3+} , and (c) S^{2-} .

SOLUTION

Analyze and Plan We are asked to write electron configurations for three ions. To do so, we first write the electron configuration of each parent atom, and then remove or add electrons to form the ions. Electrons are first removed from the orbitals having the highest value of *n*. They are added to the empty or partially filled orbitals having the lowest value of *n*.

Solve

(a) Calcium (atomic number 20) has the electron configuration [Ar]4s². To form a 2+ ion, the two outer 4s electrons must be removed, giving an ion that is isoelectronic with Ar:

$$Ca^{2+}: [Ar]$$

(b) Cobalt (atomic number 27) has the electron configuration $[Ar]4s^23d^7$. To form a 3+ ion, three electrons must be removed. As discussed in the text, the 4s electrons are removed before the 3d electrons. Consequently, we remove the two 4s electrons and one of the 3d electrons, and the electron configuration for Co^{3+} is

$$Co^{3+}$$
: [Ar] $3d^6$

(c) Sulfur (atomic number 16) has the electron configuration [Ne]3s²3p⁴. To form a 2− ion, two electrons must be added. There is room for two additional electrons in the 3p orbitals. Thus, the S²⁻ electron configuration is

$$S^{2-}$$
: [Ne] $3s^23p^6 = [Ar]$

Comment Remember that many of the common ions of the *s*- and *p*-block elements, such as Ca^{2+} and S^{2-} , have the same number of electrons as the closest noble gas. ∞ (Section 2.7)

Practice Exercise 1

The ground electron configuration of a Tc atom is $[Kr]5s^24d^5$. What is the electron configuration of a Tc³⁺ ion? (a) $[Kr]4d^4$ (b) $[Kr]5s^24d^2$ (c) $[Kr]5s^14d^3$ (d) $[Kr]5s^24d^8$ (e) $[Kr]4d^{10}$

Practice Exercise 2

Write the electron configurations for (a) Ga^{3+} , (b) Cr^{3+} , and (c) Br^{-} .

7.5 | Electron Affinity

The first ionization energy of an atom is a measure of the energy change associated with removing an electron from the atom to form a cation. For example, the first ionization energy of Cl(g), 1251 kJ/mol, is the energy change associated with the process

Ionization energy:
$$Cl(g) \longrightarrow Cl^+(g) + e^- \qquad \Delta E = 1251 \text{ kJ/mol}$$
 [7.4]
$$[\text{Ne}] 3s^2 3p^5 \qquad [\text{Ne}] 3s^2 3p^4$$

The positive value of the ionization energy means that energy must be put into the atom to remove the electron. *All ionization energies for atoms are positive: Energy must be absorbed to remove an electron.*

Most atoms can also gain electrons to form anions. The energy change that occurs when an electron is added to a gaseous atom is called the **electron affinity** because it measures the attraction, or *affinity*, of the atom for the added electron. For most atoms, energy is *released* when an electron is added. For example, the addition of an electron to a chlorine atom is accompanied by an energy change of $-349 \, \text{kJ/mol}$, the negative sign indicating that energy is released during the process. We therefore say that the electron affinity of Cl is $-349 \, \text{kJ/mol}$.*

Electron affinity:
$$Cl(g) + e^- \longrightarrow Cl^-(g)$$
 $\Delta E = -349 \text{ kJ/mol}$ [7.5] $[\text{Ne}]3s^23p^5$ $[\text{Ne}]3s^23p^6$

It is important to understand the difference between ionization energy and electron affinity: Ionization energy measures the energy change when an atom *loses* an electron, whereas electron affinity measures the energy change when an atom *gains* an electron.

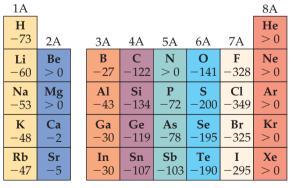

The greater the attraction between an atom and an added electron, the more negative the atom's electron affinity. For some elements, such as the noble gases, the electron affinity has a positive value, meaning that the anion is higher in energy than are the separated atom and electron:

$$Ar(g) + e^{-} \longrightarrow Ar^{-}(g) \qquad \Delta E > 0$$
[Ne]3s²3p⁶ [Ne]3s²3p⁶4s¹

The fact that the electron affinity is positive means that an electron will not attach itself to an Ar atom; the Ar ion is unstable and does not form.

▼ Figure 7.12 shows the electron affinities for the *s*- and *p*-block elements of the first five periods. Notice that the trends are not as evident as they are for ionization energy. The

Why are the electron affinities of the Group 4A elements more negative than those of the Group 5A elements?

▲ Figure 7.12 Electron affinity in kJ/mol for selected s- and p-block elements.

[▲] GO FIGURE

^{*}Two sign conventions are used for electron affinity. In most introductory texts, including this one, the thermodynamic sign convention is used: A negative sign indicates that addition of an electron is an exothermic process, as in the electron affinity for chlorine, $-349 \, \text{kJ/mol}$. Historically, however, electron affinity has been defined as the energy released when an electron is added to a gaseous atom or ion. Because $349 \, \text{kJ/mol}$ is released when an electron is added to Cl(g), the electron affinity by this convention would be $+349 \, \text{kJ/mol}$.

halogens, which are one electron shy of a filled p subshell, have the most negative electron affinities. By gaining an electron, a halogen atom forms a stable anion that has a noble-gas configuration (Equation 7.5). The addition of an electron to a noble gas, however, requires that the electron reside in a higher-energy subshell that is empty in the atom (Equation 7.6). Because occupying a higher-energy subshell is energetically unfavorable, the electron affinity is highly positive. The electron affinities of Be and Mg are positive for the same reason; the added electron would reside in a previously empty p subshell that is higher in energy.

The electron affinities of the group 5A elements are also interesting. Because these elements have half-filled *p* subshells, the added electron must be put in an orbital that is already occupied, resulting in larger electron–electron repulsions. Consequently, these elements have electron affinities that are either positive (N) or less negative than those of their neighbors to the left (P, As, Sb). Recall that in Section 7.4 we saw a discontinuity in the trends in first ionization energy for the same reason.

Electron affinities do not change greatly as we move down a group (Figure 7.12). For F, for instance, the added electron goes into a 2*p* orbital, for Cl a 3*p* orbital, for Br a 4*p* orbital, and so forth. As we proceed from F to I, therefore, the average distance between the added electron and the nucleus steadily increases, causing the electron-nucleus attraction to decrease. However, the orbital that holds the outermost electron is increasingly spread out, so that as we proceed from F to I, the electron-electron repulsions are also reduced. As a result, the reduction in the electron-nucleus attraction is counterbalanced by the reduction in electron-electron repulsions.

Give It Some Thought

What is the relationship between the value for the first ionization energy of a $CI^-(g)$ ion and the electron affinity of CI(g)?

7.6 | Metals, Nonmetals, and Metalloids

Atomic radii, ionization energies, and electron affinities are properties of individual atoms. With the exception of the noble gases, however, none of the elements exist in nature as individual atoms. To get a broader understanding of the properties of elements, we must also examine periodic trends in properties that involve large collections of atoms.

The elements can be broadly grouped as metals, nonmetals, and metalloids (Figure 7.13). ∞ (Section 2.5) Some of the distinguishing properties of metals and nonmetals are summarized in ▼ Table 7.3.

In the following sections, we explore some common patterns of reactivity across the periodic table. We will examine reactivity for selected nonmetals and metals in more depth in later chapters.

The more an element exhibits the physical and chemical properties of metals, the greater its **metallic character**. As indicated in Figure 7.13, metallic character generally increases as we proceed down a group of the periodic table and decreases as we proceed right across a period. Let's now examine the close relationships that exist between electron configurations and the properties of metals, nonmetals, and metalloids.

Table 7.3	Characteristic Pro	perties of Metals	and Nonmetals
14010 7 10	dilaiacteribac i io	perties or intetails	arra rioriricano

Metals	Nonmetals
Have a shiny luster; various colors, although most are silvery	Do not have a luster; various colors

▲ Figure 7.13 Metals, metalloids, and nonmetals.

▲ Figure 7.14 Metals are shiny, malleable, and ductile.

Metals

Most metallic elements exhibit the shiny luster we associate with metals (◀ Figure 7.14). Metals conduct heat and electricity. In general they are malleable (can be pounded into thin sheets) and ductile (can be drawn into wires). All are solids at room temperature except mercury (melting point = -39 °C), which is a liquid at room temperature. Two metals melt at slightly above room temperature, cesium at 28.4 °C and gallium at 29.8 °C. At the other extreme, many metals melt at very high temperatures. For example, tungsten, which is used for the filaments of incandescent light bulbs, melts at 3400 °C.

Metals tend to have low ionization energies (Figure 7.10) and therefore tend to form cations relatively easily. As a result, metals are oxidized (lose electrons) when they undergo chemical reactions. Among the fundamental atomic properties (radius, electron configuration, electron affinity, and so forth), first ionization energy is the best indicator of whether an element behaves as a metal or a nonmetal.

Figure 7.15 shows the oxidation states of representative ions of metals and nonmetals. As noted in Section 2.7, the charge on any alkali metal ion in a compound is always 1+, and that on any alkaline earth metal is always 2+. For atoms belonging to either of these groups, the outer s electrons are easily lost, yielding a noble-gas electron configuration. For metals belonging to groups with partially occupied p orbitals (groups 3A–7A), cations are formed either by losing only the outer p electrons (such as Sn^{2+}) or the outer s and p electrons (such as Sn⁴⁺). The charge on transition-metal ions does not follow an obvious pattern. One characteristic of the transition metals is their ability to form more than one cation. For example, compounds of Fe²⁺ and Fe³⁺ are both very common.

Give It Some Thought

Arsenic forms binary compounds with Cl and with Mg. Will it be in the same oxidation state in these two compounds?

Compounds made up of a metal and a nonmetal tend to be ionic substances. For example, most metal oxides and halides are ionic solids. To illustrate, the reaction between nickel metal and oxygen produces nickel oxide, an ionic solid containing Ni²⁺ and O²⁻ ions:

$$2 \operatorname{Ni}(s) + O_2(g) \longrightarrow 2 \operatorname{NiO}(s)$$
 [7.7]

GO FIGURE

▲ Figure 7.15 Representative oxidation states of the elements. Note that hydrogen has both positive and negative oxidation numbers, +1 and -1.

The oxides are particularly important because of the great abundance of oxygen in our environment.

Most metal oxides are basic. Those that dissolve in water react to form metal hydroxides, as in the following examples:

$$Metal\ oxide\ +\ water\ \longrightarrow\ metal\ hydroxide$$

$$Na_2O(s) + H_2O(l) \longrightarrow 2 NaOH(aq)$$
 [7.8]

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq)$$
 [7.9]

The basicity of metal oxides is due to the oxide ion, which reacts with water:

$$O^{2-}(aq) + H_2O(l) \longrightarrow 2 OH^{-}(aq)$$
 [7.10]

Even metal oxides that are insoluble in water demonstrate their basicity by reacting with acids to form a salt plus water, as illustrated in ▼ Figure 7.16:

Metal oxide
$$+$$
 acid \longrightarrow salt $+$ water

$$NiO(s) + 2 HNO_3(aq) \longrightarrow Ni(NO_3)_2(aq) + H_2O(l)$$
 [7.11]

SAMPLE

EXERCISE 7.8 Properties of Metal Oxides

- (a) Would you expect scandium oxide to be a solid, liquid, or gas at room temperature?
- (b) Write the balanced chemical equation for the reaction of scandium oxide with nitric acid.

SOLUTION

Analyze and Plan We are asked about one physical property of scandium oxide—its state at room temperature—and one chemical property—how it reacts with nitric acid.

Solve

- (a) Because scandium oxide is the oxide of a metal, we expect it to be an ionic solid. Indeed it is, with the very high melting point of 2485 °C.
- (b) In compounds, scandium has a 3+ charge, Sc^{3+} , and the oxide ion is O^{2-} . Consequently, the formula of scandium oxide is Sc₂O₃. Metal oxides tend to be basic and, therefore, to react with acids to form a salt plus water. In this case the salt is scandium nitrate, Sc(NO₃)₃:

$$Sc_2O_3(s) + 6 HNO_3(aq) \longrightarrow 2 Sc(NO_3)_3(aq) + 3 H_2O(l)$$

Practice Exercise 1

Suppose that a metal oxide of formula M₂O₃ were soluble in water. What would be the major product or products of dissolving the substance in water?

(a)
$$MH_3(aq) + O_2(g)$$
 (b) $M(s) + H_2(g) + O_2(g)$ (c) $M^{3+}(aq) + H_2O_2(aq)$ (d) $M(OH)_2(aq)$ (e) $M(OH)_3(aq)$

Practice Exercise 2

Write the balanced chemical equation for the reaction between copper(II) oxide and sulfuric acid.

GO FIGURE

Do you think sulfur is malleable?

▲ Figure 7.17 Sulfur, known to the medieval world as "brimstone," is a nonmetal.

Nonmetals

Nonmetals can be solid, liquid, or gas. They are not lustrous and generally are poor conductors of heat and electricity. Their melting points are generally lower than those of metals (although diamond, a form of carbon, is an exception and melts at 3570 °C). Under ordinary conditions, seven nonmetals exist as diatomic molecules. Five of these are gases (H₂, N₂, O₂, F₂, and Cl₂), one is a liquid (Br₂), and one is a volatile solid (I₂). Excluding the noble gases, the remaining nonmetals are solids that can be either hard, such as diamond, or soft, such as sulfur (◀ Figure 7.17).

Because of their relatively large, negative electron affinities, nonmetals tend to gain electrons when they react with metals. For example, the reaction of aluminum with bromine produces the ionic compound aluminum bromide:

$$2 \operatorname{Al}(s) + 3 \operatorname{Br}_{2}(l) \longrightarrow 2 \operatorname{AlBr}_{3}(s)$$
 [7.12]

A nonmetal will typically gain enough electrons to fill its outermost occupied p subshell, giving a noble-gas electron configuration. For example, the bromine atom gains one electron to fill its 4p subshell:

$$Br([Ar]4s^23d^{10}4p^5) + e^- \Longrightarrow Br^-([Ar]4s^23d^{10}4p^6)$$

Compounds composed entirely of nonmetals are typically molecular substances that tend to be gases, liquids, or low-melting solids at room temperature. Examples include the common hydrocarbons we use for fuel (methane, CH₄; propane, C₃H₈; octane, C₈H₁₈) and the gases HCl, NH₃, and H₂S. Many pharmaceuticals are molecules composed of C, H, N, O, and other nonmetals. For example, the molecular formula for the drug Celebrex[®] is C₁₇H₁₄F₃N₃O₂S.

Most nonmetal oxides are acidic, which means that those that dissolve in water form acids:

Nonmetal oxide + water
$$\longrightarrow$$
 acid
 $CO_2(g) + H_2O(l) \longrightarrow H_2CO_3(aq)$ [7.13]

$$P_4O_{10}(s) + 6 H_2O(l) \longrightarrow 4 H_3PO_4(aq)$$
 [7.14]

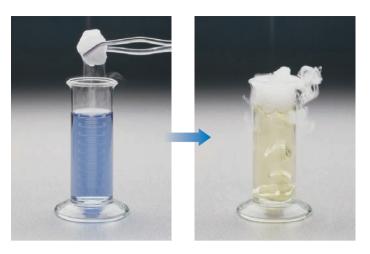

The reaction of carbon dioxide with water (Figure 7.18) accounts for the acidity of carbonated water and, to some extent, rainwater. Because sulfur is present in oil and coal, combustion of these common fuels produces sulfur dioxide and sulfur trioxide. These substances dissolve in water to produce *acid rain*, a major pollutant in many parts of the world. Like acids, most nonmetal oxides dissolve in basic solutions to form a salt plus water:

Nonmetal oxide + base
$$\longrightarrow$$
 salt + water
 $CO_2(g) + 2 \text{ NaOH}(aq) \longrightarrow \text{Na}_2CO_3(aq) + \text{H}_2O(l)$ [7.15]

Give It Some Thought

A compound ACI_3 (A is an element) has a melting point of $-112\,^{\circ}$ C. Would you expect the compound to be molecular or ionic? If you were told that A is either scandium or phosphorus, which do you think is the more likely choice?

▲ Figure 7.18 The reaction of CO₂ with water containing a bromthymol blue indicator. Initially, the blue color tells us the water is slightly basic. When a piece of solid carbon dioxide ("dry ice") is added, the color changes to yellow, indicating an acidic solution. The mist is water droplets condensed from the air by the cold CO₂ gas.

SAMPLE EXERCISE 7.9 Reactions of Nonmetal Oxides

Write a balanced chemical equation for the reaction of solid selenium dioxide, $SeO_2(s)$, with (a) water, (b) aqueous sodium hydroxide.

SOLUTION

Analyze and Plan We note that selenium is a nonmetal. We therefore need to write chemical equations for the reaction of a nonmetal oxide with water and with a base, NaOH. Nonmetal oxides are acidic, reacting with water to form an acid and with bases to form a salt and water.

Solve

(a) The reaction between selenium dioxide and water is like that between carbon dioxide and water (Equation 7.13):

$$SeO_2(s) + H_2O(l) \longrightarrow H_2SeO_3(aq)$$

(It does not matter that SeO_2 is a solid and CO_2 is a gas under ambient conditions; the point is that both are water-soluble nonmetal oxides.)

(b) The reaction with sodium hydroxide is like that in Equation 7.15:

$$SeO_2(s) + 2 NaOH(aq) \longrightarrow Na_2SeO_3(aq) + H_2O(l)$$

Practice Exercise 1

Consider the following oxides: SO_2 , Y_2O_3 , MgO, Cl_2O , N_2O_5 . How many are expected to form acidic solutions in water?

Practice Exercise 2

Write a balanced chemical equation for the reaction of solid tetraphosphorus hexoxide with water.

Metalloids

Metalloids have properties intermediate between those of metals and those of nonmetals. They may have some characteristic metallic properties but lack others. For example, the metalloid silicon *looks* like a metal (**Figure 7.19**), but it is brittle rather than malleable and does not conduct heat or electricity nearly as well as metals do. Compounds of metalloids can have characteristics of the compounds of metals or nonmetals.

Several metalloids, most notably silicon, are electrical semiconductors and are the principal elements used in integrated circuits and computer chips. One of the reasons metalloids can be used for integrated circuits is that their electrical conductivity is intermediate between that of metals and that of nonmetals. Very pure silicon is an electrical insulator, but its conductivity can be dramatically increased with the addition of specific impurities called *dopants*. This modification provides a mechanism for controlling the electrical conductivity by controlling the chemical composition. We will return to this point in Chapter 12.

▲ Figure 7.19 Elemental silicon.

▲ Figure 7.20 Sodium, like the other alkali metals, is soft enough to be cut with a knife.

7.7 | Trends for Group 1A and Group 2A Metals

As we have seen, elements in a given group possess general similarities. However, trends also exist within each group. In this section we use the periodic table and our knowledge of electron configurations to examine the chemistry of the **alkali metals** and **alkaline earth metals**.

Group 1A: The Alkali Metals

The alkali metals are soft metallic solids (Figure 7.20). All have characteristic metallic properties, such as a silvery, metallic luster, and high thermal and electrical conductivity. The name *alkali* comes from an Arabic word meaning "ashes." Many compounds of sodium and potassium, two alkali metals, were isolated from wood ashes by early chemists.

As \blacktriangledown Table 7.4 shows, the alkali metals have low densities and melting points, and these properties vary in a fairly regular way with increasing atomic number. We see the usual trends as we move down the group, such as increasing atomic radius and decreasing first ionization energy. The alkali metal of any given period has the lowest I_1 value in the period (Figure 7.10), which reflects the relative ease with which its outer s electron can be removed. As a result, the alkali metals are all very reactive, readily losing one electron to form ions carrying a 1+ charge. ∞ (Section 2.7)

The alkali metals exist in nature only as compounds. Sodium and potassium are relatively abundant in Earth's crust, in seawater, and in biological systems, always as the cations of ionic compounds. All alkali metals combine directly with most nonmetals. For example, they react with hydrogen to form hydrides and with sulfur to form sulfides:

$$2 M(s) + H_2(g) \longrightarrow 2 MH(s)$$
 [7.16]

$$2 M(s) + S(s) \longrightarrow M_2S(s)$$
 [7.17]

where M represents any alkali metal. In hydrides of the alkali metals (LiH, NaH, and so forth), hydrogen is present as H⁻, the **hydride ion**. A hydrogen atom that has *gained* an electron, this ion is distinct from the hydrogen ion, H⁺, formed when a hydrogen atom *loses* its electron.

The alkali metals react vigorously with water, producing hydrogen gas and a solution of an alkali metal hydroxide:

$$2 M(s) + 2 H2O(l) \longrightarrow 2 MOH(aq) + H2(g)$$
 [7.18]

These reactions are very exothermic (**Figure 7.21**). In many cases enough heat is generated to ignite the H₂, producing a fire or sometimes even an explosion, as in the chapter-opening photograph of K reacting with water. The reaction is even more violent for Rb and, especially, Cs, because their ionization energies are even lower than that of K.

Recall that the most common ion of oxygen is the oxide ion, O²⁻. We would therefore expect that the reaction of an alkali metal with oxygen would produce the corresponding metal oxide. Indeed, reaction of Li metal with oxygen does form lithium oxide:

$$4 \operatorname{Li}(s) + \operatorname{O}_2(g) \longrightarrow 2 \operatorname{Li}_2\operatorname{O}(s)$$
 [7.19]

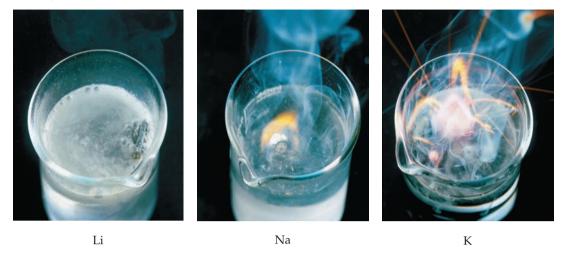

When dissolved in water, Li_2O and other soluble metal oxides form hydroxide ions from the reaction of O^{2-} ions with H_2O (Equation 7.10).

Table 7.4 Some Properties of the Alkali Metals

Element	Electron Configuration	Melting Point (°C)	Density (g/cm³)	Atomic Radius (Å)	I ₁ (kJ/mol)
Lithium	[He]2s ¹	181	0.53	1.28	520
Sodium	[Ne]3s1	98	0.97	1.66	496
Potassium	$[Ar]4s^1$	63	0.86	2.03	419
Rubidium	[Kr]5s ¹	39	1.53	2.20	403
Cesium	[Xe]6s ¹	28	1.88	2.44	376

▲ GO FIGURE

Would you expect rubidium metal to be more or less reactive with water than potassium metal?

▲ Figure 7.21 The alkali metals react vigorously with water.

The reactions of the other alkali metals with oxygen are more complex than we would anticipate. For example, when sodium reacts with oxygen, the main product is sodium *peroxide*, which contains the O_2^{2-} ion:

$$2 \operatorname{Na}(s) + \operatorname{O}_2(g) \longrightarrow \underset{\text{sodium peroxide}}{\operatorname{Na}_2 \operatorname{O}_2(s)}$$
 [7.20]

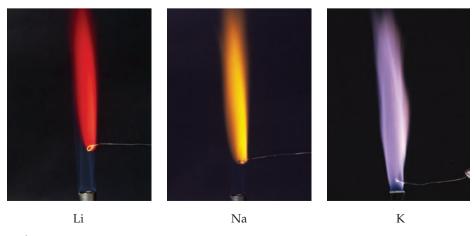

Potassium, rubidium, and cesium react with oxygen to form compounds that contain the O_2^- ion, which we call the *superoxide ion*. For example, potassium forms potassium superoxide, KO_2 :

$$K(s) + O_2(g) \longrightarrow KO_2(s)$$
 potassium superoxide [7.21]

Be aware that the reactions in Equations 7.20 and 7.21 are somewhat unexpected; in most cases, the reaction of oxygen with a metal forms the metal oxide.

As is evident from Equations 7.18 through 7.21, the alkali metals are extremely reactive toward water and oxygen. Because of this reactivity, the metals are usually stored submerged in a liquid hydrocarbon, such as mineral oil or kerosene.

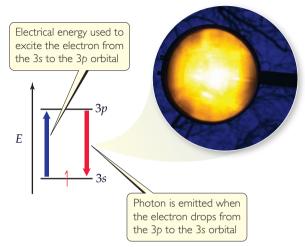

Although alkali metal ions are colorless, each emits a characteristic color when placed in a flame (▼ Figure 7.22). The ions are reduced to gaseous metal atoms in

▲ Figure 7.22 Placed in a flame, ions of each alkali metal emit light of a characteristic wavelength.

If we had potassium vapor lamps, what color would they be?

▲ Figure 7.23 The characteristic yellow light in a sodium lamp results from excited electrons in the high-energy 3*p* orbital falling back to the lower-energy 3*s* orbital.

the flame. The high temperature excites the valence electron from the ground state to a higher-energy orbital, causing the atom to be in an excited state. The atom then emits energy in the form of visible light as the electron falls back into the lower-energy orbital and the atom returns to its ground state. The light emitted is at a specific wavelength for each element, just as we saw earlier for line spectra of hydrogen and sodium. (Section 6.3) The characteristic yellow emission of sodium at 589 nm is the basis for sodium vapor lamps (Figure 7.23).

Give It Some Thought

Cesium tends to be the most reactive of the stable alkali metals (francium, Fr, is radioactive and has not been extensively studied). What *atomic* property of Cs is most responsible for its high reactivity?

SAMPLE EXERCISE 7.10 Reactions of an Alkali Metal

Write a balanced equation for the reaction of cesium metal with (a) $Cl_2(g)$, (b) $H_2O(l)$, (c) $H_2(g)$.

SOLUTION

Analyze and Plan Because cesium is an alkali metal, we expect its chemistry to be dominated by oxidation of the metal to Cs⁺ ions. Further, we recognize that Cs is far down the periodic table, which means it is among the most active of all metals and probably reacts with all three substances.

Solve The reaction between Cs and Cl_2 is a simple combination reaction between a metal and a nonmetal, forming the ionic compound CsCl:

$$2 \operatorname{Cs}(s) + \operatorname{Cl}_2(g) \longrightarrow 2 \operatorname{CsCl}(s)$$

From Equations 7.18 and 7.16, we predict the reactions of cesium with water and hydrogen to proceed as follows:

$$2 \operatorname{Cs}(s) + 2 \operatorname{H}_2\operatorname{O}(l) \longrightarrow 2 \operatorname{CsOH}(aq) + \operatorname{H}_2(g)$$
$$2 \operatorname{Cs}(s) + \operatorname{H}_2(g) \longrightarrow 2 \operatorname{CsH}(s)$$

All three reactions are redox reactions where cesium forms a Cs^+ ion. The $C\Gamma$, OH^- , and H^- are all 1- ions, which means the products have 1:1 stoichiometry with Cs^+ .

Practice Exercise 1

Consider the following three statements about the reactivity of an alkali metal M with oxygen gas:

- (i) Based on their positions in the periodic table, the expected product is the ionic oxide M₂O.
- (ii) Some of the alkali metals produce metal peroxides or metal superoxides when they react with oxygen.
- (iii) When dissolved in water, an alkali metal oxide produces a basic solution.

Which of the statements (i), (ii), and (iii) is or are true?

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

Practice Exercise 2

Write a balanced equation for the expected reaction between potassium metal and elemental sulfur, S(s).

Chemistry and Life

The Improbable Development of Lithium Drugs

Alkali metal ions tend to play an unexciting role in most chemical reactions. As noted in Section 4.2, all salts of the alkali metal ions are soluble in water, and the ions are spectators in most aqueous reactions (except for those involving the alkali metals in their elemental form, such as those in Equations 7.16 through 7.21). However, these ions play an important role in human physiology. Sodium and potassium ions, for example, are major components of blood plasma and intracellular fluid, respectively, with average concentrations of 0.1 M. These electrolytes serve as vital charge carriers in normal cellular function. In contrast,

the lithium ion has no known function in normal human physiology. Since the discovery of lithium in 1817, however, people have believed that salts of the element possessed almost mystical healing powers. There were even claims that lithium ions were an ingredient in ancient "fountain of youth" formulas. In 1927, C. L. Grigg began marketing a soft drink that contained lithium. The original unwieldy name of the beverage was "Bib-Label Lithiated Lemon-Lime Soda," which was soon changed to the simpler and more familiar name 7UP® (▶ Figure 7.24).

Because of concerns of the Food and Drug Administration, lithium was removed from 7UP® during the early 1950s. At nearly the same time, psychiatrists discovered that the lithium ion has a remarkable therapeutic effect on the mental condition called *bipolar disorder*. More than 5 million American adults each year suffer from this psychosis, undergoing severe mood swings from deep depression to a manic euphoria. The lithium ion

smoothes these mood swings, allowing the bipolar patient to function more effectively in daily life.

The antipsychotic action of Li⁺ was discovered by accident in the 1940s by Australian psychiatrist John Cade as he was researching the use of uric acid—a component of urine—to treat manic-depressive illness. He administered the acid to manic laboratory animals in the form of its most soluble salt, lithium urate, and found that many of the manic symptoms seemed to disappear. Later studies showed that uric acid has no role in the therapeutic effects observed; rather, the Li⁺ ions were responsible. Because lithium overdose can cause severe side effects in humans, including kidney failure and death, lithium salts were not approved as an-

tipsychotic drugs for humans until 1970. Today Li⁺ is usually administered orally in the form of Li₂CO₃, which is the active ingredient in prescription drugs such as Eskalith®. Lithium drugs are effective for about 70% of bipolar patients who take it.

In this age of sophisticated drug design and biotechnology, the simple lithium ion is still the most effective treatment of this destructive psychiatric disorder. Remarkably, in spite of intensive research, scientists still do not fully understand the biochemical action of lithium that leads to its therapeutic effects. Because of its similarity to Na⁺, Li⁺ is incorporated into blood plasma, where it can affect the behavior of nerve and muscle cells. Because Li⁺ has a smaller radius than Na⁺ (Figure 7.8), the way Li⁺ interacts with molecules in human cells is different from the way Na⁺ interacts with the molecules. Other studies indicate that Li⁺ alters the function of certain neurotransmitters, which might lead to its effectiveness as an antipsychotic drug.

▲ Figure 7.24 Lithium no more. The soft drink 7UP® originally contained a lithium salt that was claimed to give the beverage healthful benefits, including "an abundance of energy, enthusiasm, a clear complexion, lustrous hair, and shining eyes!" The lithium was removed from the beverage in the early 1950s, about the time that the antipsychotic action of Li⁺ was discovered.

Group 2A: The Alkaline Earth Metals

Like the alkali metals, the alkaline earth metals are all solids at room temperature and have typical metallic properties (▼ Table 7.5). Compared with the alkali metals, the alkaline earth metals are harder and denser, and melt at higher temperatures.

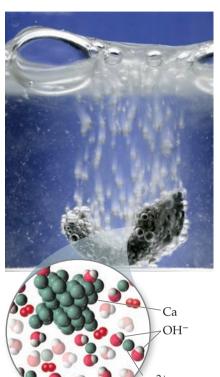

The first ionization energies of the alkaline earth metals are low but not as low as those of the alkali metals. Consequently, the alkaline earth metals are less reactive than their alkali metal neighbors. As noted in Section 7.4, the ease with which the elements lose electrons decreases as we move across a period and increases as we move down a

Table 7.5 Some Properties of the Alkaline Earth Metals

Element	Electron Configuration	Melting Point (°C)	Density (g/cm³)	Atomic Radius (Å)	I ₁ (kJ/mol)
Beryllium	$[He]2s^2$	1287	1.85	0.96	899
Magnesium	$[Ne]3s^2$	650	1.74	1.41	738
Calcium	$[Ar]4s^2$	842	1.55	1.76	590
Strontium	$[Kr]5s^2$	777	2.63	1.95	549
Barium	[Xe]6s ²	727	3.51	2.15	503

What is the cause of the bubbles that are formed? How could you test your answer?

▲ Figure 7.25 Elemental calcium reacts with water.

 H_2

group. Thus, beryllium and magnesium, the lightest alkaline earth metals, are the least reactive.

The trend of increasing reactivity within the group is shown by the way the alkaline earth metals behave in the presence of water. Beryllium does not react with either water or steam, even when heated red-hot. Magnesium reacts slowly with liquid water and more readily with steam:

$$Mg(s) + H_2O(g) \longrightarrow MgO(s) + H_2(g)$$
 [7.22]

Calcium and the elements below it react readily with water at room temperature (although more slowly than the alkali metals adjacent to them in the periodic table). The reaction between calcium and water (Figure 7.25), for example, is

$$Ca(s) + 2 H2O(l) \longrightarrow Ca(OH)2(aq) + H2(g)$$
 [7.23]

Equations 7.22 and 7.23 illustrate the dominant pattern in the reactivity of the alkaline earth elements: They tend to lose their two outer s electrons and form 2+ ions. For example, magnesium reacts with chlorine at room temperature to form MgCl₂ and burns with dazzling brilliance in air to give MgO:

$$Mg(s) + Cl_2(g) \longrightarrow MgCl_2(s)$$
 [7.24]

$$2 \operatorname{Mg}(s) + \operatorname{O}_2(g) \longrightarrow 2 \operatorname{MgO}(s)$$
 [7.25]

In the presence of O_2 , magnesium metal is protected by a thin coating of water-insoluble MgO. Thus, even though Mg is high in the activity series ∞ (Section 4.4), it can be incorporated into lightweight structural alloys used in, for example, automobile wheels. The heavier alkaline earth metals (Ca, Sr, and Ba) are even more reactive toward nonmetals than is magnesium.

The heavier alkaline earth ions give off characteristic colors when heated in a hot flame. Strontium salts produce the brilliant red color in fireworks, and barium salts produce the green color.

Like their neighbors sodium and potassium, magnesium and calcium are relatively abundant on Earth and in seawater and are essential for living organisms as cations in ionic compounds. Calcium is particularly important for growth and maintenance of bones and teeth.

Give It Some Thought

Calcium carbonate, $CaCO_3$, is often used as a dietary calcium supplement for bone health. Although $CaCO_3(s)$ is insoluble in water (Table 4.1), it can be taken orally to allow for the delivery of $Ca^{2+}(aq)$ ions to the musculoskeletal system. Why is this the case? [*Hint:* Recall the reactions of metal carbonates discussed in Section 4.3.]

7.8 | Trends for Selected Nonmetals

Hydrogen

We have seen that the chemistry of the alkali metals is dominated by the loss of their outer ns^1 electron to form cations. The $1s^1$ electron configuration of hydrogen suggests that its chemistry should have some resemblance to that of the alkali metals. The chemistry of hydrogen is much richer and more complex than that of the alkali metals, however, mainly because the ionization energy of hydrogen, $1312 \, \text{kJ/mol}$, is more than double that of any of the alkali metals. As a result, hydrogen is a nonmetal that occurs as a colorless diatomic gas, $H_2(g)$, under most conditions.

The reactivity of hydrogen with nonmetals reflects its much greater tendency to hold on to its electron relative to the alkali metals. Unlike the alkali metals, hydrogen reacts with most nonmetals to form molecular compounds in which its electron is shared with, rather than completely transferred to, the other nonmetal. For example, we have seen that sodium metal reacts vigorously with chlorine gas to produce the ionic

compound sodium chloride, in which the outermost sodium electron is completely transferred to a chlorine atom (Figure 2.21):

$$Na(s) + \frac{1}{2}Cl_2(g) \longrightarrow NaCl(s) \qquad \Delta H^{\circ} = -410.9 \text{ kJ}$$
 [7.26]

By contrast, molecular hydrogen reacts with chlorine gas to form hydrogen chloride gas, which consists of HCl molecules:

$$\frac{1}{2}H_2(g) + \frac{1}{2}Cl_2(g) \longrightarrow HCl(g) \qquad \Delta H^{\circ} = -92.3 \text{ kJ}$$

$$\stackrel{\text{molecular}}{\longrightarrow} Dl_2(g) \longrightarrow HCl(g) \qquad (7.27)$$

Hydrogen readily forms molecular compounds with other nonmetals, such as the formation of water, $H_2O(l)$; ammonia, $NH_3(g)$; and methane, $CH_4(g)$. The ability of hydrogen to form bonds with carbon is one of the most important aspects of organic chemistry, as will see in later chapters.

We have seen that, particularly in the presence of water, hydrogen does readily form H^+ ions in which the hydrogen atom has lost its electron. ∞ (Section 4.3) For example, HCl(g) dissolves in H_2O to form a solution of hydrochloric acid, HCl(aq), in which the electron of the hydrogen atom is transferred to the chlorine atom—a solution of hydrochloric acid consists largely of $H^+(aq)$ and $Cl^-(aq)$ ions stabilized by the H₂O solvent. Indeed, the ability of molecular compounds of hydrogen with nonmetals to form acids in water is one of the most important aspects of aqueous chemistry. We will discuss the chemistry of acids and bases in detail later in the text, particularly in Chapter 16.

Finally, as is typical for nonmetals, hydrogen also has the ability to gain an electron from a metal with a low ionization energy. For example, we saw in Equation 7.16 that hydrogen reacts with active metals to form solid metal hydrides that contain the hydride ion, H⁻. The fact that hydrogen can gain an electron further illustrates that it behaves much more like a nonmetal than an alkali metal.

Group 6A: The Oxygen Group

Polonium

As we proceed down group 6A, there is a change from nonmetallic to metallic character (Figure 7.13). Oxygen, sulfur, and selenium are typical nonmetals. Tellurium is a metalloid, and polonium, which is radioactive and quite rare, is a metal. Oxygen is a colorless gas at room temperature; all of the other members of group 6A are solids. Some of the physical properties of the group 6A elements are given in ▼ Table 7.6.

As we saw in Section 2.6, oxygen exists in two molecular forms, O_2 and O_3 . Because O₂ is the more common form, people generally mean it when they say "oxygen," although the name *dioxygen* is more descriptive. The O_3 form is **ozone**. The two forms of oxygen are examples of allotropes, defined as different forms of the same element. About 21% of dry air consists of O₂ molecules. Ozone is present in very small amounts in the upper atmosphere and in polluted air. It is also formed from O₂ in electrical discharges, such as in lightning storms:

$$3 O_2(g) \longrightarrow 2 O_3(g) \qquad \Delta H^{\circ} = 284.6 \text{ kJ}$$
 [7.28]

 $9.20 \, \text{g/cm}^3$

1.40

812

This reaction is strongly endothermic, telling us that O_3 is less stable than O_2 .

Some Properties of the Group 6A Elements Table 7.6 Melting Electron **Atomic** Element Configuration Point (°C) Density Radius (Å) (kJ/mol) $[He]2s^22p^4$ Oxygen -218 $1.43 \, g/L$ 0.66 1314 Sulfur $[Ne]3s^23p^4$ 1000 115 $1.96 \, \text{g/cm}^3$ 1.05 $[Ar]3d^{10}4s^24p^4$ Selenium 221 $4.82 \, \text{g/cm}^3$ 1.20 941 $[Kr]4d^{10}5s^25p^4$ Tellurium 450 $6.24 \, \text{g/cm}^3$ 1.38 869 $[Xe]4f^{14}5d^{10}6s^26p^4$

GO FIGURE

Why is it okay to store water in a bottle with a normal, nonventing cap?

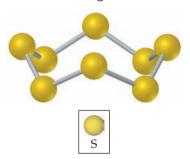

▲ Figure 7.26 Hydrogen peroxide solution in a bottle with venting cap.

GO FIGURE

Suppose it were possible to flatten the S_8 ring. What shape would you expect the flattened ring to have?

▲ Figure 7.27 Elemental sulfur exists as the S₈ molecule. At room temperature, this is the most common allotropic form of sulfur.

Although both O_2 and O_3 are colorless and therefore do not absorb visible light, O_3 absorbs certain wavelengths of ultraviolet light that O_2 does not. Because of this difference, the presence of ozone in the upper atmosphere is beneficial, filtering out harmful UV light. Ozone and oxygen also have different chemical properties. Ozone, which has a pungent odor, is a powerful oxidizing agent. Because of this property, ozone is sometimes added to water to kill bacteria or used in low levels to help to purify air. However, the reactivity of ozone also makes its presence in polluted air near Earth's surface detrimental to human health.

Oxygen has a great tendency to attract electrons from other elements (to *oxidize* them). Oxygen in combination with a metal is almost always present as the oxide ion, O^{2-} . This ion has a noble-gas configuration and is particularly stable. As shown in Figure 5.14, the formation of nonmetal oxides is also often very exothermic and thus energetically favorable.

In our discussion of the alkali metals, we noted two less common oxygen anions—the peroxide $({\rm O_2}^{2^-})$ ion and the superoxide $({\rm O_2}^-)$ ion. Compounds of these ions often react to produce an oxide and ${\rm O_2}$:

$$2 \text{ H}_2\text{O}_2(aq) \longrightarrow 2 \text{ H}_2\text{O}(l) + \text{O}_2(g) \quad \Delta H^\circ = -196.1 \text{ kJ}$$
 [7.29]

For this reason, bottles of aqueous hydrogen peroxide are topped with caps that are able to release the $O_2(g)$ produced before the pressure inside becomes too great (\triangleleft Figure 7.26).

Give It Some Thought

Hydrogen peroxide is light sensitive and so is stored in brown bottles because its 0-0 bond is relatively weak. If we assume that the brown bottle absorbs all visible wavelengths of light ∞ (Section 6.1), how might you estimate the energy of the 0-0 bond in hydrogen peroxide?

After oxygen, the most important member of group 6A is sulfur. This element exists in several allotropic forms, the most common and stable of which is the yellow solid having the molecular formula S_8 . This molecule consists of an eight-membered ring of sulfur atoms (\P Figure 7.27). Even though solid sulfur consists of S_8 rings, we usually write it simply as S(s) in chemical equations to simplify the stoichiometric coefficients.

Like oxygen, sulfur has a tendency to gain electrons from other elements to form sulfides, which contain the S^{2-} ion. In fact, most sulfur in nature is present as metal sulfides. Sulfur is below oxygen in the periodic table, and the tendency of sulfur to form sulfide anions is not as great as that of oxygen to form oxide ions. As a result, the chemistry of sulfur is more complex than that of oxygen. In fact, sulfur and its compounds (including those in coal and petroleum) can be burned in oxygen. The main product is sulfur dioxide, a major air pollutant:

$$S(s) + O_2(g) \longrightarrow SO_2(g)$$
 [7.30]

Below sulfur in group 6A is selenium, Se. This relatively rare element is essential for life in trace quantities, although it is toxic at high doses. There are many allotropes of Se, including several eight-membered ring structures that resemble the S₈ ring.

The next element in the group is tellurium, Te. Its elemental structure is even more complex than that of Se, consisting of long, twisted chains of Te—Te bonds. Both Se and Te favor the -2 oxidation state, as do O and S.

From O to S to Se to Te, the elements form larger and larger molecules and become increasingly metallic. The thermal stability of group 6A compounds with hydrogen decreases down the column: $H_2O > H_2S > H_2Se > H_2Te$, with H_2O , water, being the most stable of the series.

Group 7A: The Halogens

Some of the properties of the group 7A elements, the **halogens**, are given in ▶ **Table 7.7**. Astatine, which is both extremely rare and radioactive, is omitted because many of its properties are not yet known.

Table 7.7	Some Properties of the Halogens				
Element	Electron Configuration	Melting Point (°C)	Density	Atomic Radius (Å)	$\begin{array}{c} I_1 \\ (kJ/mol) \end{array}$
Fluorine	[He]2s ² 2p ⁵	-220	1.69 g/L	0.57	1681
Chlorine	[Ne] $3s^23p^5$	-102	$3.12\mathrm{g/L}$	1.02	1251
Bromine	$[Ar]4s^23d^{10}4p^5$	-7.3	$3.12 \mathrm{g/cm^3}$	1.20	1140
Iodine	$[Kr]5s^24d^{10}5p^5$	114	$4.94 \mathrm{g/cm^3}$	1.39	1008

Unlike the group 6A elements, all the halogens are typical nonmetals. Their melting and boiling points increase with increasing atomic number. Fluorine and chlorine are gases at room temperature, bromine is a liquid, and iodine is a solid. Each element consists of diatomic molecules: F_2 , Cl_2 , Br_2 , and I_2 (\blacktriangledown Figure 7.28).

Give It Some Thought

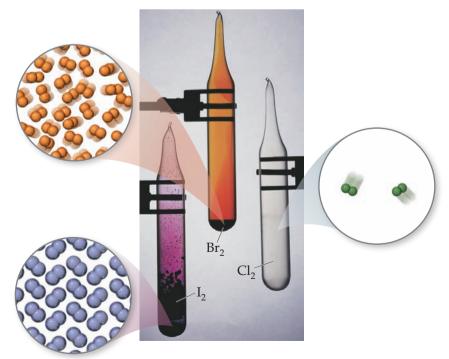

The halogens do not exist as X_8 molecules like sulfur and selenium do. Can you speculate why?

The halogens have highly negative electron affinities (Figure 7.12). Thus, it is not surprising that the chemistry of the halogens is dominated by their tendency to gain electrons from other elements to form halide ions, X^- . (In many equations X is used to indicate any one of the halogen elements.) Fluorine and chlorine are more reactive than bromine and iodine. In fact, fluorine removes electrons from almost any substance with

GO FIGURE

Why are more molecules of I_2 seen in the molecular view relative to the number of CI_2 molecules?

▲ Figure 7.28 The elemental halogens exist as diatomic molecules.

which it comes into contact, including water, and usually does so very exothermically, as in the following examples:

$$2 H_2O(l) + 2 F_2(g) \longrightarrow 4 HF(aq) + O_2(g)$$
 $\Delta H = -758.9 \text{ kJ}$ [7.31]

$$SiO_2(s) + 2 F_2(g) \longrightarrow SiF_4(g) + O_2(g)$$
 $\Delta H = -704.0 \text{ kJ}$ [7.32]

As a result, fluorine gas is difficult and dangerous to use in the laboratory, requiring specialized equipment.

Chlorine is the most industrially useful of the halogens. The annual production of chlorine is more than 20 billion pounds, making it one of the top ten most produced chemicals in the United States. (Section 1.1) Unlike fluorine, chlorine reacts slowly with water to form relatively stable aqueous solutions of HCl and HOCl (hypochlorous acid):

$$Cl_2(g) + H_2O(l) \longrightarrow HCl(aq) + HOCl(aq)$$
 [7.33]

Chlorine is often added to drinking water and swimming pools because the HOCl(*aq*) that is generated serves as a disinfectant.

The halogens react directly with most metals to form ionic halides. The halogens also react with hydrogen to form gaseous hydrogen halide compounds:

$$H_2(g) + X_2 \longrightarrow 2 HX(g)$$
 [7.34]

These compounds are all very soluble in water and dissolve to form the hydrohalic acids. As we discussed in Section 4.3, HCl(aq), HBr(aq), and HI(aq) are strong acids, whereas HF(aq) is a weak acid.

Give It Some Thought

Can you use data in Table 7.7 to estimate the atomic radius and first ionization energy of an astatine atom?

Group 8A: The Noble Gases

The group 8A elements, known as the **noble gases**, are all nonmetals that are gases at room temperature. They are all *monatomic* (that is, they consist of single atoms rather than molecules). Some physical properties of the noble-gas elements are listed in ▼ Table 7.8. The high radioactivity of radon (Rn, atomic number 86) has limited the study of its reaction chemistry and some of its properties.

The noble gases have completely filled *s* and *p* subshells. All elements of group 8A have large first ionization energies, and we see the expected decrease as we move down the column. Because the noble gases possess such stable electron configurations, they are exceptionally unreactive. In fact, until the early 1960s the elements were called the *inert gases* because they were thought to be incapable of forming chemical compounds. In 1962, Neil Bartlett at the University of British Columbia reasoned that the ionization energy of Xe

Table 7.8 Some Properties of the Noble Gases

	Electron	Boiling	Density	Atomic	I ₁
Element	Configuration	Point (K)	(g/L)	Radius* (Å)	(kJ/mol)
Helium	$1s^2$	4.2	0.18	0.28	2372
Neon	[He] $2s^22p^6$	27.1	0.90	0.58	2081
Argon	[Ne] $3s^23p^6$	87.3	1.78	1.06	1521
Krypton	$[Ar]4s^23d^{10}4p^6$	120	3.75	1.16	1351
Xenon	$[Kr]5s^24d^{10}5p^6$	165	5.90	1.40	1170
Radon	$[Xe]6s^24f^{14}5d^{10}6p^6$	211	9.73	1.50	1037

^{*}Only the heaviest of the noble-gas elements form chemical compounds. Thus, the atomic radii for the lighter noble gas elements are estimated values.

might be low enough to allow it to form compounds. For this to happen, Xe would have to react with a substance with an extremely high ability to remove electrons from other substances, such as fluorine. Bartlett synthesized the first noble-gas compound by combining Xe with the fluorine-containing compound PtF₆. Xenon also reacts directly with $F_2(g)$ to form the molecular compounds XeF₂, XeF₄, and XeF₆. Krypton has a higher I_1 value than xenon and is therefore less reactive. In fact, only a single stable compound of krypton is known, KrF₂. In 2000, Finnish scientists reported the first neutral molecule that contains argon, the HArF molecule, which is stable only at low temperatures.

SAMPLE INTEGRATIVE EXERCISE

Putting Concepts Together

The element bismuth (Bi, atomic number 83) is the heaviest member of group 5A. A salt of the element, bismuth subsalicylate, is the active ingredient in Pepto-Bismol®, an over-the-counter medication for gastric distress.

- (a) Based on values presented in Figure 7.7 and Tables 7.5 and 7.6, what might you expect for the bonding atomic radius of bismuth?
- (b) What accounts for the general increase in atomic radius going down the group 5A elements?
- (c) Another major use of bismuth has been as an ingredient in low-melting metal alloys, such as those used in fire sprinkler systems and in typesetting. The element itself is a brittle white crystalline solid. How do these characteristics fit with the fact that bismuth is in the same periodic group with such nonmetallic elements as nitrogen and phosphorus?
- (d) Bi_2O_3 is a basic oxide. Write a balanced chemical equation for its reaction with dilute nitric acid. If 6.77 g of Bi_2O_3 is dissolved in dilute acidic solution to make 0.500 L of solution, what is the molarity of the solution of Bi^{3+} ion?
- (e) ²⁰⁹Bi is the heaviest stable isotope of any element. How many protons and neutrons are present in this nucleus?
- (f) The density of Bi at 25 °C is 9.808 g/cm³. How many Bi atoms are present in a cube of the element that is 5.00 cm on each edge? How many moles of the element are present?

SOLUTION

- (a) Bismuth is directly below antimony, Sb, in group 5A. Based on the observation that atomic radii increase as we go down a column, we would expect the radius of Bi to be greater than that of Sb, which is 1.39 Å. We also know that atomic radii generally decrease as we proceed from left to right in a period. Tables 7.5 and 7.6 each give an element in the same period, namely Ba and Po. We would therefore expect that the radius of Bi is smaller than that of Ba (2.15 Å) and larger than that of Po (1.40 Å). We also see that in other periods, the difference in radius between the neighboring group 5A and group 6A elements is relatively small. We might therefore expect that the radius of Bi is slightly larger than that of Po—much closer to the radius of Po than to the radius of Ba. The tabulated value for the atomic radius on Bi is 1.48 Å, in accord with our expectations.
- **(b)** The general increase in radius with increasing atomic number in the group 5A elements occurs because additional shells of electrons are being added, with corresponding increases in nuclear charge. The core electrons in each case largely screen the outermost electrons from the nucleus, so the effective nuclear charge does not vary greatly as we go to higher atomic numbers. However, the principal quantum number, n, of the outermost electrons steadily increases, with a corresponding increase in orbital radius.
- (c) The contrast between the properties of bismuth and those of nitrogen and phosphorus illustrates the general rule that there is a trend toward increased metallic character as we move down in a given group. Bismuth, in fact, is a metal. The increased metallic character occurs because the outermost electrons are more readily lost in bonding, a trend that is consistent with its lower ionization energy.
- (d) Following the procedures described in Section 4.2 for writing molecular and net ionic equations, we have the following:

Molecular equation:
$$Bi_2O_3(s) + 6 HNO_3(aq) \longrightarrow 2 Bi(NO_3)_3(aq) + 3 H_2O(l)$$

Net ionic equation: $Bi_2O_3(s) + 6 H^+(aq) \longrightarrow 2 Bi^{3+}(aq) + 3 H_2O(l)$

In the net ionic equation, nitric acid is a strong acid and $Bi(NO_3)_3$ is a soluble salt, so we need to show only the reaction of the solid with the hydrogen ion forming the $Bi^{3+}(aq)$ ion and water. To calculate the concentration of the solution, we proceed as follows (Section 4.5):

$$\frac{6.77~\text{g Bi}_2\text{O}_3}{0.500~\text{L soln}} \times \frac{1~\text{mol Bi}_2\text{O}_3}{466.0~\text{g Bi}_2\text{O}_3} \times \frac{2~\text{mol Bi}^{3^+}}{1~\text{mol Bi}_2\text{O}_3} = \frac{0.0581~\text{mol Bi}^{3^+}}{\text{L soln}} = 0.0581~\text{M}$$

- (e) Recall that the atomic number of any element is the number of protons and electrons in a neutral atom of the element. ∞ (Section 2.3) Bismuth is element 83; there are therefore 83 protons in the nucleus. Because the atomic mass number is 209, there are 209 83 = 126 neutrons in the nucleus.
- (f) We can use the density and the atomic weight to determine the number of moles of Bi, and then use Avogadro's number to convert the result to the number of atoms. ∞ (Sections 1.4 and 3.4) The volume of the cube is $(5.00)^3$ cm³ = 125 cm³. Then we have

$$125\,cm^3\,Bi\,\times\frac{9.808\,g\,Bi}{1\,cm^3}\times\frac{1\,mol\,Bi}{209.0\,g\,Bi}\,=\,5.87\,mol\,Bi$$

$$5.87~{
m mol~Bi} imes rac{6.022 imes 10^{23}~{
m atom~Bi}}{1~{
m mol~Bi}} = 3.53 imes 10^{24}~{
m atoms~Bi}$$

Chapter Summary and Key Terms

DEVELOPMENT OF THE PERIODIC TABLE (INTRODUCTION AND SECTION 7.1) The periodic table was first developed by Mendeleev and Meyer on the basis of the similarity in chemical and physical properties exhibited by certain elements. Moseley established that each element has a unique atomic number, which added more order to the periodic table.

We now recognize that elements in the same column of the periodic table have the same number of electrons in their valence orbitals. This similarity in valence electronic structure leads to the similarities among elements in the same group. The differences among elements in the same group arise because their valence orbitals are in different shells.

EFFECTIVE NUCLEAR CHARGE (SECTION 7.2) Many properties of atoms depend on the **effective nuclear charge**, which is the portion of the nuclear charge that an outer electron experiences after accounting for repulsions by other electrons in the atom. The core electrons are very effective in screening the outer electrons from the full charge of the nucleus, whereas electrons in the same shell do not screen each other as effectively. Because the actual nuclear charge increases as we progress through a period, the effective nuclear charge experienced by valence electrons increases as we move left to right across a period.

SIZES OF ATOMS AND IONS (SECTION 7.3) The size of an atom can be gauged by its **bonding atomic radius**, which is based on measurements of the distances separating atoms in their chemical compounds. In general, atomic radii increase as we go down a column in the periodic table and decrease as we proceed left to right across a row.

Cations are smaller than their parent atoms; anions are larger than their parent atoms. For ions of the same charge, size increases going down a column of the periodic table. An **isoelectronic series** is a series of ions that has the same number of electrons. For such a series, size decreases with increasing nuclear charge as the electrons are attracted more strongly to the nucleus.

IONIZATION ENERGY (SECTION 7.4) The first **ionization energy** of an atom is the minimum energy needed to remove an electron from the atom in the gas phase, forming a cation. The second ionization energy is the energy needed to remove a second electron, and so forth. Ionization energies show a sharp increase after all the valence electrons have been removed because of the much higher effective nuclear charge experienced by the core electrons. The first ionization energies of the elements show periodic trends that are opposite those seen for atomic radii, with smaller atoms having higher first ionization energies. Thus, first ionization energies decrease as we go down a column and increase as we proceed left to right across a row.

We can write electron configurations for ions by first writing the electron configuration of the neutral atom and then removing or adding the appropriate number of electrons. For cations, electrons are removed first from the orbitals of the neutral atom with the largest value of n. If there are two valence orbitals with the same value of n (such as n0, then the electrons are lost first from the orbital with a higher value of n1 (in this case, n2). For anions, electrons are added to orbitals in the reverse order.

element is the energy change upon adding an electron to an atom in the gas phase, forming an anion. A negative electron affinity means that energy is released when the electron is added; hence, when the electron affinity is negative the anion is stable. By contrast, a positive electron affinity means that the anion is not stable relative to the separated atom and electron, in which case its exact value cannot be measured. In general, electron affinities become more negative as we proceed from left to right across the periodic table. The halogens have the most negative electron affinities. The electron affinities of the noble gases are positive because the added electron would have to occupy a new, higher-energy subshell.

METALS, NONMETALS, AND METALLOIDS (SECTION 7.6) The elements can be categorized as metals, nonmetals, and metalloids. Most elements are metals; they occupy the left side and the middle of the periodic table. Nonmetals appear in the upper-right section of the table. Metalloids occupy a narrow band between the metals and nonmetals. The tendency of an element to exhibit the properties of metals, called the metallic character, increases as we proceed down a column and decreases as we proceed from left to right across a row.

Metals have a characteristic luster, and they are good conductors of heat and electricity. When metals react with nonmetals, the metal atoms are oxidized to cations and ionic substances are generally formed. Most metal oxides are basic; they react with acids to form salts and water.

Nonmetals lack metallic luster and are generally poor conductors of heat and electricity. Several are gases at room temperature. Compounds composed entirely of nonmetals are generally molecular. Nonmetals usually form anions in their reactions with metals. Nonmetal oxides are acidic; they react with bases to form salts and water. Metalloids have properties that are intermediate between those of metals and nonmetals.

TRENDS FOR GROUP 1A AND GROUP 2A METALS (SECTION 7.7)

The periodic properties of the elements can help us understand the properties of groups of the representative elements. The alkali metals

(group 1A) are soft metals with low densities and low melting points. They have the lowest ionization energies of the elements. As a result, they are very reactive toward nonmetals, easily losing their outer s electron to form 1+ ions.

The alkaline earth metals (group 2A) are harder and denser, and have higher melting points than the alkali metals. They are also very reactive toward nonmetals, although not as reactive as the alkali metals. The alkaline earth metals readily lose their two outer s electrons to form 2+ ions. Both alkali and alkaline earth metals react with hydrogen to form ionic substances that contain the hydride ion, H^- .

TRENDS FOR SELECTED NONMETALS (SECTION 7.8) Hydrogen is a nonmetal with properties that are distinct from any of the groups of the periodic table. It forms molecular compounds with other nonmetals, such as oxygen and the halogens.

Oxygen and sulfur are the most important elements in group 6A. Oxygen is usually found as a diatomic molecule, O_2 . Ozone, O_3 , is an important allotrope of oxygen. Oxygen has a strong tendency to gain electrons from other elements, thus oxidizing them. In combination with metals, oxygen is usually found as the oxide ion, O_2^{-} , although salts of the peroxide ion, O_2^{2-} , and superoxide ion, O_2^{-} , are sometimes formed. Elemental sulfur is most commonly found as S_8 molecules. In combination with metals, it is most often found as the sulfide ion, S_2^{-} .

The halogens (group 7A) exist as diatomic molecules. The halogens have the most negative electron affinities of the elements. Thus, their chemistry is dominated by a tendency to form 1— ions, especially in reactions with metals.

The **noble gases** (group 8A) exist as monatomic gases. They are very unreactive because they have completely filled s and p subshells. Only the heaviest noble gases are known to form compounds, and they do so only with very active nonmetals, such as fluorine.

Learning Outcomes After studying this chapter, you should be able to:

- Explain the meaning of effective nuclear charge, $Z_{\rm eff}$, and how $Z_{\rm eff}$ depends on nuclear charge and electron configuration. (Section 7.2)
- Predict the trends in atomic radii, ionic radii, ionization energy, and electron affinity by using the periodic table. (Sections 7.2, 7.3, 7.4, and 7.5)
- Explain how the radius of an atom changes upon losing electrons to form a cation or gaining electrons to form an anion. (Section 7.3)
- Write the electron configurations of ions. (Section 7.3)
- Explain how the ionization energy changes as we remove successive electrons, and the jump in ionization energy that occurs when the ionization corresponds to removing a core electron. (Section 7.4)
- Explain how irregularities in the periodic trends for electron affinity can be related to electron configuration. (Section 7.5)

- Explain the differences in chemical and physical properties of metals and nonmetals, including the basicity of metal oxides and the acidity of nonmetal oxides. (Section 7.6)
- Correlate atomic properties, such as ionization energy, with electron configuration, and explain how these relate to the chemical reactivity and physical properties of the alkali and alkaline earth metals (groups 1A and 2A). (Section 7.7)
- Write balanced equations for the reactions of the group 1A and 2A metals with water, oxygen, hydrogen, and the halogens. (Sections 7.7 and 7.8)
- List and explain the unique characteristics of hydrogen. (Section 7.7)
- Correlate the atomic properties (such as ionization energy, electron configuration, and electron affinity) of group 6A, 7A, and 8A elements with their chemical reactivity and physical properties. (Section 7.8)

Estimating effective nuclear charge

Exercises

Visualizing Concepts

7.1 As discussed in the text, we can draw an analogy between the attraction of an electron to a nucleus and the act of perceiving light from a lightbulb—in essence, the more nuclear charge the electron "sees," the greater the attraction. (a) Using this analogy, discuss how screening by core electrons is analogous to putting a frosted-glass lampshade between the lightbulb and your eyes, as shown in the illustration.

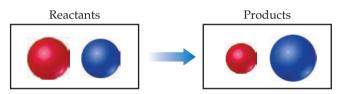

- (b) Explain how we could mimic moving to the right in a row of the periodic table by changing the wattage of the lightbulb. (c) How would you change the wattage of the bulb and/or change the frosted glass to mimic the effect of moving down a column of the periodic table? [Section 7.2]
- **7.2** Which of these spheres represents F, which represents Br, and which represents Br-? [Section 7.3]

7.3 Consider the Mg^{2+} , Cl^- , K^+ , and Se^{2-} ions. The four spheres below represent these four ions, scaled according to ionic size. (a) Without referring to Figure 7.8, match each ion to its appropriate sphere. (b) In terms of size, between which of the spheres would you find the (i) Ca^{2+} and (ii) S^{2-} ions? [Section 7.3]

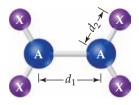

7.4 In the following reaction

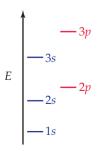

which sphere represents a metal and which represents a non-metal? Explain your answer. [Section 7.3]

7.5 Consider the A_2X_4 molecule depicted here, where A and X are elements. The A—A bond length in this molecule is d_1 , and the four A—X bond lengths are each d_2 . (a) In terms of d_1 and d_2 , how could you define the bonding atomic radii of atoms A and X? (b) In terms of d_1 and d_2 , what would you predict for the X—X bond length of an X_2 molecule? [Section 7.3]

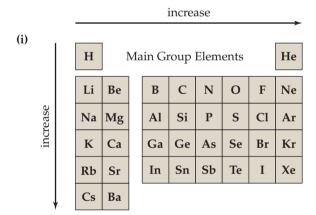

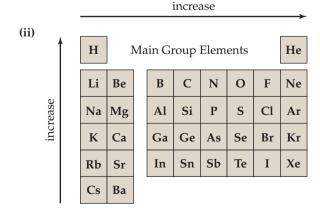

7.6 Shown below is a qualitative diagram of the atomic orbital energies for an Na atom. The number of orbitals in each subshell is not shown.

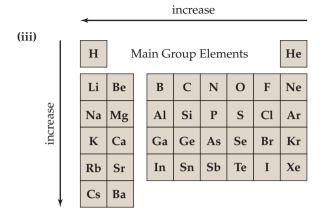

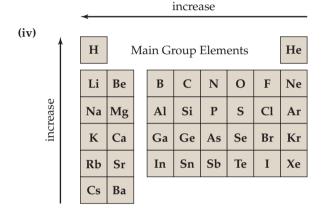

(a) Are all of the subshells for n = 1, n = 2, and n = 3 shown? If not, what is missing?

- (b) The 2s and 2p energy levels are shown as different. Which of the following is the best explanation for why this is the case? (i) The 2s and 2p energy levels have different energies in the hydrogen atom, so of course they will have different energies in the sodium atom, (ii) The energy of the 2p orbital is higher than that of the 2s in all many-electron atoms. (iii) The 2s level in Na has electrons in it, whereas the 2p does not.
- (c) Which of the energy levels holds the highest-energy electron in a sodium atom?
- (d) A sodium vapor lamp (Figure 7.23) operates by using electricity to excite the highest-energy electron to the next highest-energy level. Light is produced when the excited electron drops back to the lower level. Which two energy levels are involved in this process for the Na atom? [Section 7.7]
- 7.7 (a) Which of the following charts below shows the general periodic trends for each of the following properties of the main-group elements (you can neglect small deviations going either across a row or down a column of the periodic table)?
 (1) Bonding atomic radius, (2) first ionization energy, and
 (3) metallic character. (b) Do any of the charts show the general periodic trends in the electron affinities of the maingroup elements? [Sections 7.2–7.6]

7.8 An element X reacts with $F_2(g)$ to form the molecular product shown here. (a) Write a balanced equation for this reaction (do not worry about the phases for X and the product). (b) Do you think that X is a metal or nonmetal? Explain. [Section 7.6]

Periodic Table; Effective Nuclear Charge (Sections 7.1 and 7.2)

- 7.9 (a) Evaluate the expressions $2 \times 1, 2 \times (1 + 3), 2 \times (1 + 3 + 5),$ and $2 \times (1 + 3 + 5 + 7).$ (b) How do the atomic numbers of the noble gases relate to the numbers from part (a)? (c) What topic discussed in Chapter 6 is the source of the number "2" in the expressions in part (a)?
- **7.10** The prefix *eka-* comes from the Sanskrit word for "one." Mendeleev used this prefix to indicate that the unknown element was one place away from the known element that followed the prefix. For example, *eka-silicon*, which we now call germanium, is one element below silicon. Mendeleev also predicted the existence of *eka-manganese*, which was not experimentally confirmed until 1937 because this element is radioactive and does not occur in nature. Based on the periodic table shown in Figure 7.1, what do we now call the element Mendeleev called *eka-manganese*.

- 7.11 You might have expected that the elements would have been discovered in order of their relative abundance in the Earth's crust (Figure 1.6), but this is not the case. Suggest a general reason.
- 7.12 (a) Moseley's experiments on X rays emitted from atoms led to the concept of atomic numbers. Where exactly do these X rays come from? Draw an energy-level diagram to explain. (b) Why are chemical and physical properties of the elements more closely related to atomic numbers than they are to atomic weights?
- **7.13** (a) What is meant by the term *effective nuclear charge*? (b) How does the effective nuclear charge experienced by the valence electrons of an atom vary going from left to right across a period of the periodic table?
- 7.14 Which of the following statements about effective nuclear charge for the outermost valence electron of an atom is *incorrect*? (i) The effective nuclear charge can be thought of as the true nuclear charge minus a screening constant due to the other electrons in the atom. (ii) Effective nuclear charge increases going left to right across a row of the periodic table. (iii) Valence electrons screen the nuclear charge more effectively than do core electrons. (iv) The effective nuclear charge shows a sudden decrease when we go from the end of one row to the beginning of the next row of the periodic table. (v) The change in effective nuclear charge going down a column of the periodic table is generally less than that going across a row of the periodic table.
- 7.15 Detailed calculations show that the value of $Z_{\rm eff}$ for the outermost electrons in Na and K atoms is 2.51+ and 3.49+, respectively. (a) What value do you estimate for $Z_{\rm eff}$ experienced by the outermost electron in both Na and K by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (b) What values do you estimate for $Z_{\rm eff}$ using Slater's rules? (c) Which approach gives a more accurate estimate of $Z_{\rm eff}$? (d) Does either method of approximation account for the gradual increase in $Z_{\rm eff}$ that occurs upon moving down a group? (e) Predict $Z_{\rm eff}$ for the outermost electrons in the Rb atom based on the calculations for Na and K.
- 7.16 Detailed calculations show that the value of $Z_{\rm eff}$ for the outermost electrons in Si and Cl atoms is 4.29+ and 6.12+, respectively. (a) What value do you estimate for $Z_{\rm eff}$ experienced by the outermost electron in both Si and Cl by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (b) What values do you estimate for $Z_{\rm eff}$ using Slater's rules? (c) Which approach gives a more accurate estimate of $Z_{\rm eff}$? (d) Which method of approximation more accurately accounts for the steady increase in $Z_{\rm eff}$ that occurs upon moving left to right across a period? (e) Predict $Z_{\rm eff}$ for a valence electron in P, phosphorus, based on the calculations for Si and Cl.
- **7.17** Which will experience the greater effective nuclear charge, the electrons in the n=3 shell in Ar or the n=3 shell in Kr? Which will be closer to the nucleus?
- **7.18** Arrange the following atoms in order of increasing effective nuclear charge experienced by the electrons in the n=3 electron shell: K, Mg, P, Rh, Ti.

Atomic and Ionic Radii (Section 7.3)

7.19 (a) Because an exact outer boundary cannot be measured or even calculated for an atom, how are atomic radii determined? (b) What is the difference between a bonding radius and a nonbonding radius? (c) For a given element, which one is larger? (d) If a free atom reacts to become part of a molecule, would you say that the atom gets smaller or larger?

- 7.20 (a) Why does the quantum mechanical description of manyelectron atoms make it difficult to define a precise atomic radius?(b) When nonbonded atoms come up against one another, what determines how closely the nuclear centers can approach?
- 7.21 Tungsten has the highest melting point of any metal in the periodic table: 3422 °C. The distance between W atoms in tungsten metal is 2.74 Å. (a) What is the atomic radius of a tungsten atom in this environment? (This radius is called the *metallic radius*.)
 (b) If you put tungsten metal under high pressure, predict what would happen to the distance between W atoms.
- **7.22** Which of the following statements about the bonding atomic radii in Figure 7.7 is *incorrect*? (i) For a given period, the radii of the representative elements generally decrease from left to right across period. (ii) The radii of the representative elements for the n=3 period are all larger than those of the corresponding elements in the n=2 period. (iii) For most of the representative elements, the change in radius from the n=2 to the n=3 period is greater than the change in radius from n=3 to n=4. (iv) The radii of the transition elements generally increase moving from left to right within a period. (v) The large radii of the Group 1A elements are due to their relatively small effective nuclear charges.
- **7.23** Estimate the As—I bond length from the data in Figure 7.7 and compare your value to the experimental As—I bond length in arsenic triiodide, AsI₃, 2.55 Å.
- **7.24** The experimental Bi—I bond length in bismuth triiodide, BiI₃, is 2.81 Å. Based on this value and data in Figure 7.7, predict the atomic radius of Bi.
- **7.25** Using only the periodic table, arrange each set of atoms in order from largest to smallest: (a) K, Li, Cs; (b) Pb, Sn, Si; (c) F, O, N.
- **7.26** Using only the periodic table, arrange each set of atoms in order of increasing radius: (a) Ba, Ca, Na; (b) In, Sn, As; (c) Al, Be, Si.
- **7.27** Identify each statement as true or false: (a) Cations are larger than their corresponding neutral atoms. (b) Li⁺ is smaller than Li. (c) Cl⁻ is bigger than I⁻.
- **7.28** Explain the following variations in atomic or ionic radii:
 - (a) $I^- > I > I^+$
 - **(b)** $Ca^{2+} > Mg^{2+} > Be^{2+}$
 - (c) $Fe > Fe^{2+} > Fe^{3+}$
- 7.29 Which neutral atom is isoelectronic with each of the following ions? Ga^{3+} , Zr^{4+} , Mn^{7+} , I^- , Pb^{2+} .
- 7.30 Some ions do not have a corresponding neutral atom that has the same electron configuration. For each of the following ions, identify the neutral atom that has the same number of electrons and determine if this atom has the same electron configuration. If such an atom does not exist, explain why.
 (a) Cl⁻, (b) Sc³⁺, (c) Fe²⁺, (d) Zn²⁺, (e) Sn⁴⁺.
- 7.31 Consider the isoelectronic ions F⁻ and Na⁺. (a) Which ion is smaller? (b) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant, *S*, calculate Z_{eff} for the 2*p* electrons in both ions. (c) Repeat this calculation using Slater's rules to estimate the screening constant, *S*. (d) For isoelectronic ions, how are effective nuclear charge and ionic radius related?
- **7.32** Consider the isoelectronic ions Cl^- and K^+ . (a) Which ion is smaller? (b) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute nothing to the screening constant, S, calculate Z_{eff} for these two ions. (c) Repeat this calculation using Slater's rules to estimate

- the screening constant, *S.* (**d**) For isoelectronic ions, how are effective nuclear charge and ionic radius related?
- 7.33 Consider S, Cl, and K and their most common ions. (a) List the atoms in order of increasing size. (b) List the ions in order of increasing size. (c) Explain any differences in the orders of the atomic and ionic sizes.
- 7.34 Arrange each of the following sets of atoms and ions, in order of increasing size: (a) Se²⁻, Te²⁻, Se; (b) Co³⁺, Fe²⁺, Fe³⁺; (c) Ca, Ti⁴⁺, Sc³⁺; (d) Be²⁺, Na⁺, Ne.
- 7.35 Provide a brief explanation for each of the following: (a) O²⁻ is larger than O. (b) S²⁻ is larger than O²⁻. (c) S²⁻ is larger than K⁺. (d) K⁺ is larger than Ca²⁺.
- 7.36 In the ionic compounds LiF, NaCl, KBr, and RbI, the measured cation–anion distances are 2.01 Å (Li–F), 2.82 Å (Na–Cl), 3.30 Å (K–Br), and 3.67 Å (Rb–I), respectively. (a) Predict the cation–anion distance using the values of ionic radii given in Figure 7.8. (b) Calculate the difference between the experimentally measured ion–ion distances and the ones predicted from Figure 7.8. Assuming we have an accuracy of 0.04 Å in the measurement, would you say that the two sets of ion–ion distances are the same or not? (c) What estimates of the cation–anion distance would you obtain for these four compounds using bonding atomic radii? Are these estimates as accurate as the estimates using ionic radii?

Ionization Energies; Electron Affinities (Sections 7.4 and 7.5)

- 7.37 Write equations that show the processes that describe the first, second, and third ionization energies of an aluminum atom. Which process would require the least amount of energy?
- **7.38** Write equations that show the process for (a) the first two ionization energies of lead and (b) the fourth ionization energy of zirconium.
- 7.39 (a) Why does Li have a larger first ionization energy than Na?
 (b) The difference between the third and fourth ionization energies of scandium is much larger than that of titanium. Why? (c) Why does Li have a much larger second ionization energy than Be?
- 7.40 Identify each statement as true or false: (a) Ionization energies are always negative quantities. (b) Oxygen has a larger first ionization energy than fluorine. (c) The second ionization energy of an atom is always greater than its first ionization energy. (d) The third ionization energy is the energy needed to ionize three electrons from a neutral atom.
- 7.41 (a) What is the general relationship between the size of an atom and its first ionization energy? (b) Which element in the periodic table has the largest ionization energy? Which has the smallest?
- 7.42 (a) What is the trend in first ionization energies as one proceeds down the group 7A elements? Explain how this trend relates to the variation in atomic radii. (b) What is the trend in first ionization energies as one moves across the fourth period from K to Kr? How does this trend compare with the trend in atomic radii?
- **7.43** Based on their positions in the periodic table, predict which atom of the following pairs will have the smaller first ionization energy: (a) Cl, Ar; (b) Be, Ca; (c) K, Co; (d) S, Ge; (e) Sn, Te.
- 7.44 For each of the following pairs, indicate which element has the smaller first ionization energy: (a) Ti, Ba; (b) Ag, Cu; (c) Ge, Cl; (d) Pb, Sb.

- **7.45** Write the electron configurations for the following ions, and determine which have noble-gas configurations: (a) Co²⁺, (b) Sn²⁺, (c) Zr⁴⁺, (d) Ag⁺, (e) S²⁻.
- 7.46 Write the electron configurations for the following ions, and determine which have noble-gas configurations: (a) Ru³⁺, (b) As³⁻, (c) Y³⁺, (d) Pd²⁺, (e) Pb²⁺, (f) Au³⁺.
- **7.47** Find three examples of ions in the periodic table that have an electron configuration of nd^8 (n = 3, 4, 5, ...).
- **7.48** Find three atoms in the periodic table whose ions have an electron configuration of nd^6 (n = 3, 4, 5, ...).
- **7.49** The first ionization energy and electron affinity of Ar are both positive values. (a) What is the significance of the positive value in each case? (b) What are the units of electron affinity?
- **7.50** If the electron affinity for an element is a negative number, does it mean that the anion of the element is more stable than the neutral atom? Explain.
- **7.51** Although the electron affinity of bromine is a negative quantity, it is positive for Kr. Use the electron configurations of the two elements to explain the difference.
- 7.52 What is the relationship between the ionization energy of an anion with a 1 charge such as F⁻ and the electron affinity of the neutral atom, F?
- **7.53** Consider the first ionization energy of neon and the electron affinity of fluorine. (a) Write equations, including electron configurations, for each process. (b) These two quantities have opposite signs. Which will be positive, and which will be negative? (c) Would you expect the magnitudes of these two quantities to be equal? If not, which one would you expect to be larger?
- 7.54 Consider the following equation:

$$Ca^+(g) + e^- \longrightarrow Ca(g)$$

Which of the following statements are true? (i) The energy change for this process is the electron affinity of the Ca⁺ ion. (ii) The energy change for this process is the negative of the first ionization energy of the Ca atom. (iii) The energy change for this process is the negative of the electron affinity of the Ca atom.

Properties of Metals and Nonmetals (Section 7.6)

- **7.55** (a) Does metallic character increase, decrease, or remain unchanged as one goes from left to right across a row of the periodic table? (b) Does metallic character increase, decrease, or remain unchanged as one goes down a column of the periodic table? (c) Are the periodic trends in (a) and (b) the same as or different from those for first ionization energy?
- 7.56 You read the following statement about two elements X and Y: One of the elements is a good conductor of electricity, and the other is a semiconductor. Experiments show that the first ionization energy of X is twice as great as that of Y. Which element has the greater metallic character?
- 7.57 Discussing this chapter, a classmate says, "An element that commonly forms a cation is a metal." Do you agree or disagree? Explain your answer.
- **7.58** Discussing this chapter, a classmate says, "Since elements that form cations are metals and elements that form anions are nonmetals, elements that do not form ions are metalloids." Do you agree or disagree? Explain your answer.
- **7.59** Predict whether each of the following oxides is ionic or molecular: SnO₂, Al₂O₃, CO₂, Li₂O, Fe₂O₃, H₂O.

- **7.60** Some metal oxides, such as Sc_2O_3 , do not react with pure water, but they do react when the solution becomes either acidic or basic. Do you expect Sc_2O_3 to react when the solution becomes acidic or when it becomes basic? Write a balanced chemical equation to support your answer.
- 7.61 (a) What is meant by the terms acidic oxide and basic oxide?(b) How can we predict whether an oxide will be acidic or basic based on its composition?
- **7.62** Arrange the following oxides in order of increasing acidity: CO₂, CaO, Al₂O₃, SO₃, SiO₂, P₂O₅.
- 7.63 Chlorine reacts with oxygen to form Cl₂O₇. (a) What is the name of this product (see Table 2.6)? (b) Write a balanced equation for the formation of Cl₂O₇(*l*) from the elements. (c) Under usual conditions, Cl₂O₇ is a colorless liquid with a boiling point of 81 °C. Is this boiling point expected or surprising? (d) Would you expect Cl₂O₇ to be more reactive toward H⁺(aq) or OH⁻(aq)? (e) If the oxygen in Cl₂O₇ is considered to have the -2 oxidation state, what is the oxidation state of the Cl? What is the electron configuration of Cl in this oxidation state?
- [7.64] An element X reacts with oxygen to form XO₂ and with chlorine to form XCl₄. XO₂ is a white solid that melts at high temperatures (above 1000 °C). Under usual conditions, XCl₄ is a colorless liquid with a boiling point of 58 °C. (a) XCl₄ reacts with water to form XO₂ and another product. What is the likely identity of the other product? (b) Do you think that element X is a metal, nonmetal, or metalloid? (c) By using a sourcebook such as the *CRC Handbook of Chemistry and Physics*, try to determine the identity of element X.
- 7.65 Write balanced equations for the following reactions:

 (a) barium oxide with water,
 (b) iron(II) oxide with perchloric acid,
 (c) sulfur trioxide with water,
 (d) carbon dioxide with aqueous sodium hydroxide.
- **7.66** Write balanced equations for the following reactions: (a) potassium oxide with water, (b) diphosphorus trioxide with water, (c) chromium(III) oxide with dilute hydrochloric acid, (d) selenium dioxide with aqueous potassium hydroxide.

Group Trends in Metals and Nonmetals (Sections 7.7 and 7.8)

- 7.67 (a) Why is calcium generally more reactive than magnesium?(b) Why is calcium generally less reactive than potassium?
- **7.68** Silver and rubidium both form +1 ions, but silver is far less reactive. Suggest an explanation, taking into account the ground-state electron configurations of these elements and their atomic radii.
- 7.69 Write a balanced equation for the reaction that occurs in each of the following cases: (a) Potassium metal is exposed to an atmosphere of chlorine gas. (b) Strontium oxide is added to water. (c) A fresh surface of lithium metal is exposed to oxygen gas. (d) Sodium metal reacts with molten sulfur.
- 7.70 Write a balanced equation for the reaction that occurs in each of the following cases: (a) Cesium is added to water.(b) Strontium is added to water. (c) Sodium reacts with oxygen. (d) Calcium reacts with iodine.
- 7.71 (a) As described in Section 7.7, the alkali metals react with hydrogen to form hydrides and react with halogens to form halides. Compare the roles of hydrogen and halogens in these reactions. How are the forms of hydrogen and halogens in the products alike? (b) Write balanced equations for the reaction of fluorine

with calcium and for the reaction of hydrogen with calcium. What are the similarities among the products of these reactions?

7.72 Potassium and hydrogen react to form the ionic compound potassium hydride. (a) Write a balanced equation for this reaction. (b) Use data in Figures 7.10 and 7.12 to determine the energy change in kJ/mol for the following two reactions:

$$K(g) + H(g) \longrightarrow K^{+}(g) + H^{-}(g)$$

 $K(g) + H(g) \longrightarrow K^{-}(g) + H^{+}(g)$

- (c) Based on your calculated energy changes in (b), which of these reactions is energetically more favorable (or less unfavorable)? (d) Is your answer to (c) consistent with the description of potassium hydride as containing hydride ions?
- 7.73 Compare the elements bromine and chlorine with respect to the following properties: (a) electron configuration, (b) most common ionic charge, (c) first ionization energy, (d) reactivity toward water, (e) electron affinity, (f) atomic radius. Account for the differences between the two elements.
- 7.74 Little is known about the properties of astatine, At, because of its rarity and high radioactivity. Nevertheless, it is possible for us to make many predictions about its properties. (a) Do

- you expect the element to be a gas, liquid, or solid at room temperature? Explain. (b) Would you expect At to be a metal, nonmetal, or metalloid? Explain. (c) What is the chemical formula of the compound it forms with Na?
- 7.75 Until the early 1960s the group 8A elements were called the inert gases. (a) Why was the term *inert gases* dropped?(b) What discovery triggered this change in name? (c) What name is applied to the group now?
- 7.76 (a) Why does xenon react with fluorine, whereas neon does not? (b) Using appropriate reference sources, look up the bond lengths of Xe—F bonds in several molecules. How do these numbers compare to the bond lengths calculated from the atomic radii of the elements?
- 7.77 Write a balanced equation for the reaction that occurs in each of the following cases: (a) Ozone decomposes to dioxygen.(b) Xenon reacts with fluorine. (Write three different equations.)(c) Sulfur reacts with hydrogen gas. (d) Fluorine reacts with water.
- 7.78 Write a balanced equation for the reaction that occurs in each of the following cases: (a) Chlorine reacts with water. (b) Barium metal is heated in an atmosphere of hydrogen gas. (c) Lithium reacts with sulfur. (d) Fluorine reacts with magnesium metal.

Additional Exercises

- 7.79 Consider the stable elements through lead (Z=82). In how many instances are the atomic weights of the elements out of order relative to the atomic numbers of the elements?
- [7.80] Figure 7.4 shows the radial probability distribution functions for the 2s orbitals and 2p orbitals. (a) Which orbital, 2s or 2p, has more electron density close to the nucleus? (b) How would you modify Slater's rules to adjust for the difference in electronic penetration of the nucleus for the 2s and 2p orbitals?
- 7.81 (a) If the core electrons were totally effective at screening the valence electrons and the valence electrons provided no screening for each other, what would be the effective nuclear charge acting on the 3s and 3p valence electrons in P?(b) Repeat these calculations using Slater's rules. (c) Detailed calculations indicate that the effective nuclear charge is 5.6+ for the 3s electrons and 4.9+ for the 3p electrons. Why are the values for the 3s and 3p electrons different? (d) If you remove a single electron from a P atom, which orbital will it come from?
- **7.82** As we move across a period of the periodic table, why do the sizes of the transition elements change more gradually than those of the representative elements?
- 7.83 In the series of group 5A hydrides, of general formula MH₃, the measured bond distances are P—H, 1.419 Å; As—H, 1.519 Å; Sb—H, 1.707 Å. (a) Compare these values with those estimated by use of the atomic radii in Figure 7.7. (b) Explain the steady increase in M—H bond distance in this series in terms of the electron configurations of the M atoms.
- **7.84** In Table 7.8, the bonding atomic radius of neon is listed as 0.58 Å, whereas that for xenon is listed as 1.40 Å. A classmate of yours states that the value for Xe is more realistic than the one for Ne. Is she correct? If so, what is the basis for her statement?
- 7.85 The As As bond length in elemental arsenic is 2.48 Å. The Cl Cl bond length in Cl₂ is 1.99 Å. (a) Based on these data, what is the predicted As Cl bond length in arsenic trichloride, AsCl₃, in which each of the three Cl atoms is bonded to the As atom? (b) What bond length is predicted for AsCl₃, using the atomic radii in Figure 7.7?

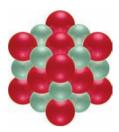

- **7.86** The following observations are made about two hypothetical elements A and B: The A A and B B bond lengths in elemental A and B are 2.36 and 1.94 Å, respectively. A and B react to form the binary compound AB₂, which has a *linear* structure (that is \angle B A B = 180°). Based on these statements, predict the separation between the two B nuclei in a molecule of AB₂.
- 7.87 Elements in group 7A in the periodic table are called the halogens; elements in group 6A are called the chalcogens. (a) What is the most common oxidation state of the chalcogens compared to the halogens? (b) For each of the following periodic properties, state whether the halogens or the chalcogens have larger values: atomic radii, ionic radii of the most common oxidation state, first ionization energy, second ionization energy.
- **7.88** Note from the following table that there is a significant increase in atomic radius upon moving from Y to La whereas the radii of Zr to Hf are the same. Suggest an explanation for this effect.

	Atomic Radii (Å)						
Sc	1.70	Ti	1.60				
Y	1.90	Zr	1.75				
La	2.07	Hf	1.75				

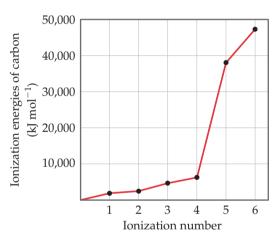

[7.89] (a) Which ion is smaller, Co³⁺ or Co⁴⁺? (b) In a lithium-ion battery that is discharging to power a device, for every Li⁺ that inserts into the lithium cobalt oxide electrode, a Co⁴⁺ ion must be reduced to a Co³⁺ ion to balance charge. Using the *CRC Handbook of Chemistry and Physics* or other standard reference, find the ionic radii of Li⁺, Co³⁺, and Co⁴⁺. Order these ions from smallest to largest. (c) Will the lithium cobalt electrode expand or contract as lithium ions are inserted? (d) Lithium is not nearly as abundant as sodium. If sodium ion batteries were developed that function as lithium ion ones, do you think "sodium cobalt oxide" would still work as the electrode material? Explain. (e) If you don't think cobalt would work as the

295

[7.90] The ionic substance strontium oxide, SrO, forms from the reaction of strontium metal with molecular oxygen. The arrangement of the ions in solid SrO is analogous to that in solid NaCl:

- (a) Write a balanced equation for the formation of SrO(s) from its elements. (b) Based on the ionic radii in Figure 7.8, predict the length of the side of the cube in the figure (the distance from the center of an atom at one corner to the center of an atom at a neighboring corner). (c) The density of SrO is $5.10 \, \text{g/cm}^3$. Given your answer to part (b), how many formula units of SrO are contained in the cube shown here?
- **7.91** Explain the variation in the ionization energies of carbon, as displayed in this graph:

- 7.92 Group 4A elements have much more negative electron affinities than their neighbors in groups 3A and 5A (see Figure 7.12). Which of the following statements best explains this observation?
 (i) The group 4A elements have much higher first ionization energies than their neighbors in groups 3A and 5A. (ii) The addition of an electron to a group 4A element leads to a half-filled np³ outer electron configuration. (iii) The group 4A elements have unusually large atomic radii. (iv) The group 4A elements are easier to vaporize than are the group 3A and 5A elements.
- **7.93** In the chemical process called *electron transfer*, an electron is transferred from one atom or molecule to another. (We will talk about electron transfer extensively in Chapter 20.) A simple electron transfer reaction is

$$A(g) + A(g) \longrightarrow A^{+}(g) + A^{-}(g)$$

In terms of the ionization energy and electron affinity of atom A, what is the energy change for this reaction? For a representative nonmetal such as chlorine, is this process exothermic? For a representative metal such as sodium, is this process exothermic?

7.94 (a) Use orbital diagrams to illustrate what happens when an oxygen atom gains two electrons. (b) Why does O³⁻ not exist?

- [7.95] Use electron configurations to explain the following observations: (a) The first ionization energy of phosphorus is greater than that of sulfur. (b) The electron affinity of nitrogen is lower (less negative) than those of both carbon and oxygen. (c) The second ionization energy of oxygen is greater than the first ionization energy of fluorine. (d) The third ionization energy of manganese is greater than those of both chromium and iron.
- **7.96** Identify two ions that have the following ground-state electron configurations: (a) [Ar], (b) [Ar] $3d^5$, (c) [Kr] $5s^24d^{10}$.
- 7.97 Which of the following chemical equations is connected to the definitions of (a) the first ionization energy of oxygen,(b) the second ionization energy of oxygen, and (c) the electron affinity of oxygen?

(i)
$$O(g) + e^{-} \longrightarrow O^{-}(g)$$
 (ii) $O(g) \longrightarrow O^{+}(g) + e^{-}$ (iii) $O(g) + 2e^{-} \longrightarrow O^{2-}(g)$ (iv) $O(g) \longrightarrow O^{2+}(g) + 2e^{-}$ (v) $O^{+}(g) \longrightarrow O^{2+}(g) + e^{-}$

7.98 The electron affinities, in kJ/mol, for the group 1B and group 2B metals are as follows:

Cu -119	Zn > 0
Ag -126	Cd > 0
Au -223	Hg > 0

- (a) Why are the electron affinities of the group 2B elements greater than zero? (b) Why do the electron affinities of the group 1B elements become more negative as we move down the group? [*Hint*: Examine the trends in the electron affinities of other groups as we proceed down the periodic table.]
- 7.99 Hydrogen is an unusual element because it behaves in some ways like the alkali metal elements and in other ways like nonmetals. Its properties can be explained in part by its electron configuration and by the values for its ionization energy and electron affinity. (a) Explain why the electron affinity of hydrogen is much closer to the values for the alkali elements than for the halogens. (b) Is the following statement true? "Hydrogen has the smallest bonding atomic radius of any element that forms chemical compounds." If not, correct it. If it is, explain in terms of electron configurations. (c) Explain why the ionization energy of hydrogen is closer to the values for the halogens than for the alkali metals. (d) The hydride ion is H⁻. Write out the process corresponding to the first ionization energy of the hydride ion. (e) How does the process in part (d) compare to the process for the electron affinity of a neutral hydrogen atom?
- [7.100] The first ionization energy of the oxygen molecule is the energy required for the following process:

$$O_2(g) \longrightarrow O_2^+(g) + e^-$$

The energy needed for this process is 1175 kJ/mol, very similar to the first ionization energy of Xe. Would you expect O_2 to react with F_2 ? If so, suggest a product or products of this reaction.

[7.101] It is possible to define *metallic character* as we do in this book and base it on the reactivity of the element and the ease with which it loses electrons. Alternatively, one could measure how well electricity is conducted by each of the elements to determine how "metallic" the elements are. On the basis of conductivity, there is not much of a trend in the periodic

table: Silver is the most conductive metal, and manganese the least. Look up the first ionization energies of silver and manganese; which of these two elements would you call more metallic based on the way we define it in this book?

- 7.102 Which of the following is the expected product of the reaction of K(s) and H₂(g)? (i) KH(s), (ii) K₂H(s), (iii) KH₂(s), (iv) K₂H₂(s), or (v) K(s) and H₂(g) will not react with one another.
- 7.103 Elemental cesium reacts more violently with water than does elemental sodium. Which of the following best explains this difference in reactivity? (i) Sodium has greater metallic character than does cesium. (ii) The first ionization energy of cesium is less than that of sodium. (iii) The electron affinity of sodium is smaller than that of cesium. (iv) The effective nuclear charge for cesium is less than that of sodium. (v) The atomic radius of cesium is smaller than that of sodium.
- 7.104 (a) One of the alkali metals reacts with oxygen to form a solid white substance. When this substance is dissolved in water, the solution gives a positive test for hydrogen peroxide, H₂O₂. When the solution is tested in a burner flame, a lilac-purple flame is produced. What is the likely identity of the metal?
 (b) Write a balanced chemical equation for the reaction of the white substance with water.
- 7.105 Zinc in its 2+ oxidation state is an essential metal ion for life. Zn²+ is found bound to many proteins that are involved in biological processes, but unfortunately Zn²+ is hard to detect by common chemical methods. Therefore, scientists who are interested in studying Zn²+-containing proteins frequently substitute Cd²+ for Zn²+, since Cd²+ is easier to detect. (a) On the basis of the properties of the elements and ions discussed in this chapter and their positions in the periodic table, describe the pros and cons of using Cd²+ as a Zn²+ substitute. (b) Proteins that speed up (catalyze) chemical reactions are called *enzymes*. Many enzymes are required for proper metabolic reactions in the body. One problem with using Cd²+ to replace Zn²+ in enzymes is that Cd²+ substitution can decrease or even eliminate enzymatic activity. Can you suggest a different metal ion that might replace Zn²+ in enzymes instead of Cd²+? Justify your answer.

- [7.106] A historian discovers a nineteenth-century notebook in which some observations, dated 1822, were recorded on a substance thought to be a new element. Here are some of the data recorded in the notebook: "Ductile, silver-white, metallic looking. Softer than lead. Unaffected by water. Stable in air. Melting point: 153 °C. Density: 7.3 g/cm³. Electrical conductivity: 20% that of copper. Hardness: About 1% as hard as iron. When 4.20 g of the unknown is heated in an excess of oxygen, 5.08 g of a white solid is formed. The solid could be sublimed by heating to over 800 °C." (a) Using information in the text and the CRC Handbook of Chemistry and Physics, and making allowances for possible variations in numbers from current values, identify the element reported. (b) Write a balanced chemical equation for the reaction with oxygen. (c) Judging from Figure 7.1, might this nineteenth-century investigator have been the first to discover a new element?
- 7.107 In April 2010, a research team reported that it had made Element 117. This discovery was confirmed in 2012 by additional experiments. Write the ground-state electron configuration for Element 117 and estimate values for its first ionization energy, electron affinity, atomic size, and common oxidation state based on its position in the periodic table.
- 7.108 We will see in Chapter 12 that semiconductors are materials that conduct electricity better than nonmetals but not as well as metals. The only two elements in the periodic table that are technologically useful semiconductors are silicon and germanium. Integrated circuits in computer chips today are based on silicon. Compound semiconductors are also used in the electronics industry. Examples are gallium arsenide, GaAs; gallium phosphide, GaP; cadmium sulfide, CdS; and cadmium selenide, CdSe. (a) What is the relationship between the compound semiconductors' compositions and the positions of their elements on the periodic table relative to Si and Ge? (b) Workers in the semiconductor industry refer to "II-VI" and "III-V" materials, using Roman numerals. Can you identify which compound semiconductors are II-VI and which are III-V? (c) Suggest other compositions of compound semiconductors based on the positions of their elements in the periodic table.

Integrative Exercises

[7.109] Moseley established the concept of atomic number by studying X rays emitted by the elements. The X rays emitted by some of the elements have the following wavelengths:

Element	Wavelength (Å)
Ne	14.610
Ca	3.358
Zn	1.435
Zr	0.786
Sn	0.491

- (a) Calculate the frequency, ν , of the X rays emitted by each of the elements, in Hz. (b) Plot the square root of ν versus the atomic number of the element. What do you observe about the plot? (c) Explain how the plot in part (b) allowed Moseley to predict the existence of undiscovered elements. (d) Use the result from part (b) to predict the X-ray wavelength emitted by iron. (e) A particular element emits X rays with a wavelength of 0.980 Å. What element do you think it is?
- [7.110] (a) Write the electron configuration for Li and estimate the effective nuclear charge experienced by the valence electron.

- (b) The energy of an electron in a one-electron atom or ion equals $(-2.18 \times 10^{-18} \, \text{J}) \left(\frac{Z^2}{n^2}\right)$, where Z is the nuclear charge and n is the principal quantum number of the electron. Estimate the first ionization energy of Li. (c) Compare the result of your calculation with the value reported in Table 7.4 and explain the difference. (d) What value of the effective nuclear charge gives the proper value for the ionization energy? Does this agree with your explanation in part (c)?
- [7.111] One way to measure ionization energies is ultraviolet photoelectron spectroscopy (PES), a technique based on the photoelectric effect. (Section 6.2) In PES, monochromatic light is directed onto a sample, causing electrons to be emitted. The kinetic energy of the emitted electrons is measured. The difference between the energy of the photons and the kinetic energy of the electrons corresponds to the energy needed to remove the electrons (that is, the ionization energy). Suppose that a PES experiment is performed in which mercury vapor is irradiated with ultraviolet light of wavelength 58.4 nm. (a) What is the energy of a photon of this light, in eV? (b) Write an equation that shows the process corresponding to the first ionization energy of

- Hg. (c) The kinetic energy of the emitted electrons is measured to be 10.75 eV. What is the first ionization energy of Hg, in kJ/mol? (d) Using Figure 7.10, determine which of the halogen elements has a first ionization energy closest to that of mercury.
- 7.112 Mercury in the environment can exist in oxidation states 0, +1, and +2. One major question in environmental chemistry research is how to best measure the oxidation state of mercury in natural systems; this is made more complicated by the fact that mercury can be reduced or oxidized on surfaces differently than it would be if it were free in solution. XPS, X-ray photoelectron spectroscopy, is a technique related to PES (see Exercise 7.111), but instead of using ultraviolet light to eject valence electrons, X rays are used to eject core electrons. The energies of the core electrons are different for different oxidation states of the element. In one set of experiments, researchers examined mercury contamination of minerals in water. They measured the XPS signals that corresponded to electrons ejected from mercury's 4f orbitals at 105 eV, from an X-ray source that provided 1253.6 eV of energy. The oxygen on the mineral surface gave emitted electron energies at 531 eV, corresponding to the 1s orbital of oxygen. Overall the researchers concluded that oxidation states were +2 for Hg and -2 for O. (a) Calculate the wavelength of the X rays used in this experiment. (b) Compare the energies of the 4f electrons in mercury and the 1s electrons in oxygen from these data to the first ionization energies of mercury and oxygen from the data in this chapter. (c) Write out the ground-state electron configurations for Hg^{2+} and O^{2-} ; which electrons are the valence electrons in each case? (d) Use Slater's rules to estimate $Z_{\rm eff}$ for the 4f and valence electrons of Hg²⁺ and O²⁻; assume for this purpose that all the inner electrons with (n-3) or less screen a full +1.
- [7.113] When magnesium metal is burned in air (Figure 3.6), two products are produced. One is magnesium oxide, MgO. The other is the product of the reaction of Mg with molecular nitrogen, magnesium nitride. When water is added to magnesium nitride, it reacts to form magnesium oxide and ammonia gas.

 (a) Based on the charge of the nitride ion (Table 2.5), predict the formula of magnesium nitride. (b) Write a balanced equation for the reaction of magnesium nitride with water. What is the driving force for this reaction? (c) In an experiment, a piece of magnesium ribbon is burned in air in a crucible. The mass of the

- mixture of MgO and magnesium nitride after burning is 0.470 g. Water is added to the crucible, further reaction occurs, and the crucible is heated to dryness until the final product is 0.486 g of MgO. What was the mass percentage of magnesium nitride in the mixture obtained after the initial burning? (d) Magnesium nitride can also be formed by reaction of the metal with ammonia at high temperature. Write a balanced equation for this reaction. If a 6.3-g Mg ribbon reacts with 2.57 g NH₃(g) and the reaction goes to completion, which component is the limiting reactant? What mass of $H_2(g)$ is formed in the reaction? (e) The standard enthalpy of formation of solid magnesium nitride is -461.08 kJ/mol. Calculate the standard enthalpy change for the reaction between magnesium metal and ammonia gas.
- 7.114 (a) The measured Bi Br bond length in bismuth tribromide, BiBr₃, is 2.63 Å. Based on this value and the data in Figure 7.8, predict the atomic radius of Bi. (b) Bismuth tribromide is soluble in acidic solution. It is formed by treating solid bismuth(III) oxide with aqueous hydrobromic acid. Write a balanced chemical equation for this reaction. (c) While bismuth(III) oxide is soluble in acidic solutions, it is insoluble in basic solutions such as NaOH(aq). Based on these properties, is bismuth characterized as a metallic, metalloid, or nonmetallic element? (d) Treating bismuth with fluorine gas forms BiF5. Use the electron configuration of Bi to explain the formation of a compound with this formulation. (e) While it is possible to form BiF₅ in the manner just described, pentahalides of bismuth are not known for the other halogens. Explain why the pentahalide might form with fluorine but not with the other halogens. How does the behavior of bismuth relate to the fact that xenon reacts with fluorine to form compounds but not with the other halogens?
- 7.115 Potassium superoxide, KO_2 , is often used in oxygen masks (such as those used by firefighters) because KO_2 reacts with CO_2 to release molecular oxygen. Experiments indicate that 2 mol of $KO_2(s)$ react with each mole of $CO_2(g)$. (a) The products of the reaction are $K_2CO_3(s)$ and $O_2(g)$. Write a balanced equation for the reaction between $KO_2(s)$ and $CO_2(g)$. (b) Indicate the oxidation number for each atom involved in the reaction in part (a). What elements are being oxidized and reduced? (c) What mass of $KO_2(s)$ is needed to consume 18.0 g $CO_2(g)$? What mass of $O_2(g)$ is produced during this reaction?

Design an Experiment

In this chapter we have seen that the reaction of potassium metal with oxygen leads to a product that we might not expect, namely, potassium superoxide, $KO_2(s)$. Let's design some experiments to learn more about this unusual product.

- (a) One of your team members proposes that the capacity to form a superoxide such as KO₂ is related to a low value for the first ionization energy. How would you go about testing this hypothesis for the metals of group 1A? What other periodic property of the alkali metals might be considered as a factor favoring superoxide formation?
- (b) $KO_2(s)$ is the active ingredient in many breathing masks used by firefighters because it can be used as a source of $O_2(g)$. In principle, $KO_2(s)$ can react with both major components of human breath, $H_2O(g)$ and $CO_2(g)$, to produce $O_2(g)$ and other products (all of which follow the expected patterns of reactivity we have seen). Predict the other products in these reactions and design experiments to determine whether $KO_2(s)$ does actually react with both $H_2O(g)$ and $CO_2(g)$.
- (c) Propose an experiment to determine whether either of the reactions in part (b) is more important in the operation of a firefighter's breathing mask.
- (d) The reaction of K(s) and $O_2(g)$ leads to a mixture of $KO_2(s)$ and $K_2O(s)$. Use ideas presented in this exercise to design an experiment to determine the percentages of $KO_2(s)$ and $K_2O(s)$ in the product mixture that results from the reaction of K(s) with excess $O_2(g)$.

Basic Concepts of Chemical Bonding

Whenever two atoms or ions are strongly held together, we say there is a **chemical bond** between them. There are three general types of chemical bonds: *ionic*, *covalent*, and *metallic*. We can get a glimpse of these three types of bonds by thinking about the simple act of using a stainless-steel

spoon to add table salt to a glass of water (**Figure 8.1**). Table salt is sodium chloride, NaCl, which consists of sodium ions, Na $^+$, and chloride ions, Cl $^-$. The structure is held together by **ionic bonds**, which are due to the electrostatic attractions between oppositely charged ions. The water consists mainly of H_2O molecules. The hydrogen and oxygen atoms are bonded to one another through **covalent bonds**, in which molecules are formed by the sharing of electrons between atoms. The spoon consists mainly of iron metal, in which Fe atoms are connected to one another via **metallic bonds**, which are formed by electrons that are relatively free to move through the metal. These different substances—NaCl, H_2O and Fe metal—behave as they do because of the ways in which their constituent atoms are connected to one another. For example, NaCl readily dissolves in water, but Fe metal does not.

What determines the type of bonding in any substance? How do the characteristics of these bonds give rise to different physical and chemical properties? The keys to answering the first question are found in the electronic structure of the atoms involved, discussed in Chapters 6 and 7. In this chapter and the next, we examine the relationship between the electronic structure of atoms and the ionic and covalent chemical bonds they form. We will discuss metallic bonding in Chapter 12.

▶ CHEMICAL BONDING AS ART. The Atomium is a 110-m-high steel sculpture commissioned for the 1958 World's Fair in Brussels. The nine spheres represent atoms, and the connecting rods evoke the chemical bonds holding them together. One sphere sits in the center of a cube formed by the other eight, a common arrangement of the atoms in metallic elements, such as iron.

8.1 LEWIS SYMBOLS AND THE OCTET RULE

We begin with descriptions of the three main types of chemical bonds: *ionic*, *covalent*, and *metallic*. In evaluating bonding, *Lewis symbols* provide a useful shorthand for keeping track of valence electrons.

8.2 IONIC BONDING We learn that in ionic substances, the atoms are held together by the electrostatic attractions between ions of opposite charge. We discuss the energetics of forming ionic substances and describe the *lattice energy* of these substances.

8.3 COVALENT BONDING We examine the bonding in molecular substances, in which atoms bond by sharing one or more electron pairs. In general, the electrons are shared in such a way that each atom attains an *octet* of electrons.

8.4 BOND POLARITY AND ELECTRONEGATIVITY

We define *electronegativity* as the ability of an atom in a compound to attract electrons to itself. In general, electron pairs are shared unequally between atoms with different electronegativities, leading to *polar covalent bonds*.

8.5 DRAWING LEWIS STRUCTURES We see that *Lewis structures* are a simple yet powerful way of predicting covalent

bonding patterns in molecules. In addition to the octet rule, we see that the concept of *formal charge* can be used to identify the dominant Lewis structure.

8.6 RESONANCE STRUCTURES We find that in some cases, more than one equivalent Lewis structure can be drawn for a molecule or polyatomic ion. The bonding description in such cases is a blend of two or more *resonance structures*.

8.7 EXCEPTIONS TO THE OCTET RULE We recognize that the octet rule is more of a guideline than an absolute rule. Exceptions to the rule include molecules with an odd number of electrons,

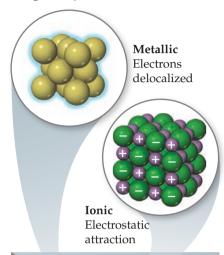

molecules where large differences in electronegativity prevent an atom from completing its octet, and molecules where an element from period 3 or below in the periodic table attains more than an octet of electrons.

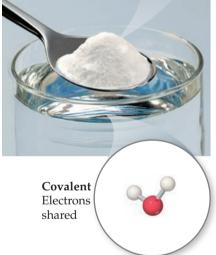

8.8 STRENGTHS AND LENGTHS OF COVALENT BONDS We observe that bond strengths vary with the number of shared electron pairs as well as other factors. We use *average bond enthalpy* values to estimate the enthalpies of reactions in cases where thermodynamic data are unavailable.

GO FIGURE

If the white powder were sugar, $C_{12}H_{22}O_{11}$, how would we have to change this picture?

▲ Figure 8.1 lonic, covalent, and metallic bonds. The three different substances shown here are held together by different types of chemical bonds.

8.1 | Lewis Symbols and the Octet Rule

The electrons involved in chemical bonding are the *valence electrons*, which, for most atoms, are those in the outermost occupied shell. (Section 6.8) The American chemist G. N. Lewis (1875–1946) suggested a simple way of showing the valence electrons in an atom and tracking them during bond formation, using what are now known as either *Lewis electron-dot symbols* or simply Lewis symbols.

The **Lewis symbol** for an element consists of the element's chemical symbol plus a dot for each valence electron. Sulfur, for example, has the electron configuration $\lceil \text{Ne} \rceil 3s^2 3p^4$ and therefore six valence electrons. Its Lewis symbol is

The dots are placed on the four sides of the symbol—top, bottom, left, and right—and each side can accommodate up to two electrons. All four sides are equivalent, which means that the choice of on which sides to place two electrons rather than one electron is arbitrary. In general, we spread out the dots as much as possible. In the Lewis symbol for S, for instance, we prefer the dot arrangement shown rather than the arrangement having two electrons on three of the sides and none on the fourth.

The electron configurations and Lewis symbols for the main-group elements of periods 2 and 3 are shown in ▼ Table 8.1. Notice that the number of valence electrons in any representative element is the same as the element's group number. For example, the Lewis symbols for oxygen and sulfur, members of group 6A, both show six dots.

Give It Some Thought

Are all these Lewis symbols for CI correct?

The Octet Rule

Atoms often gain, lose, or share electrons to achieve the same number of electrons as the noble gas closest to them in the periodic table. The noble gases have very stable electron arrangements, as evidenced by their high ionization energies, low affinity for additional electrons, and general lack of chemical reactivity. (Section 7.8) Because all the noble gases except He have eight valence electrons, many atoms undergoing reactions end up with eight valence electrons. This observation has led to a guideline known as the **octet rule**: Atoms tend to gain, lose, or share electrons until they are surrounded by eight valence electrons.

Table 8.1 Lewis Symbols

Group	Element	Electron Configuration	Lewis Symbol	Element	Electron Configuration	Lewis Symbol
1A	Li	[He]2s ¹	Li•	Na	[Ne]3s ¹	Na∙
2A	Be	[He]2 <i>s</i> ²	·Be•	Mg	[Ne] $3s^2$	·Mg·
3A	В	[He] $2s^22p^1$	٠Ġ٠	Al	[Ne] $3s^23p^1$	·Ál·
4A	С	[He] $2s^22p^2$	٠Ċ٠	Si	$[\mathrm{Ne}]3s^23p^2$	٠Ṣi٠
5A	N	[He] $2s^22p^3$	·Ņ:	P	$[\mathrm{Ne}]3s^23p^3$	·Ė:
6A	O	[He] $2s^22p^4$:ọ:	S	[Ne] $3s^23p^4$: ṣ :
7A	F	[He] $2s^22p^5$	·F:	Cl	[Ne] $3s^23p^5$	∙Ċl:
8A	Ne	[He] $2s^22p^6$:Ņe:	Ar	[Ne] $3s^23p^6$:Ḥr:

An octet of electrons consists of full *s* and *p* subshells in an atom. In a Lewis symbol, an octet is shown as four pairs of valence electrons arranged around the element symbol, as in the Lewis symbols for Ne and Ar in Table 8.1. There are exceptions to the octet rule, as we will see later in the chapter, but it provides a useful framework for introducing many important concepts of bonding.

8.2 | Ionic Bonding

Ionic substances generally result from the interaction of metals on the left side of the periodic table with nonmetals on the right side (excluding the noble gases, group 8A). For example, when sodium metal, Na(s), is brought into contact with chlorine gas, $Cl_2(g)$, a violent reaction ensues (∇ Figure 8.2). The product of this very exothermic reaction is sodium chloride, NaCl(s):

$$Na(s) + \frac{1}{2}Cl_2(g) \longrightarrow NaCl(s)$$
 $\Delta H_f^{\circ} = -410.9 \text{ kJ}$ [8.1]

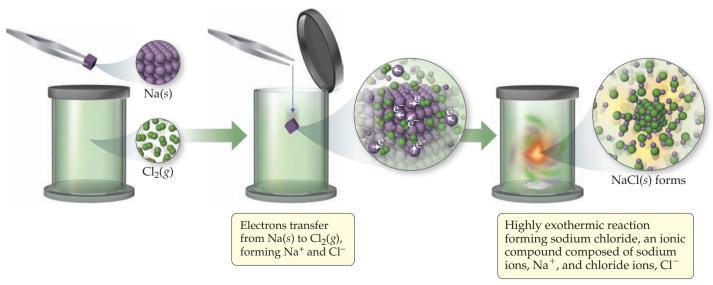

Sodium chloride is composed of Na⁺ and Cl⁻ ions arranged in a three-dimensional array (Figure 8.3).

The formation of Na⁺ from Na and Cl⁻ from Cl₂ indicates that an electron has been lost by a sodium atom and gained by a chlorine atom—we say there has been an *electron transfer* from the Na atom to the Cl atom. Two of the atomic properties discussed in Chapter 7 give us an indication of how readily electron transfer occurs: ionization energy, which indicates how easily an electron can be removed from an atom; and electron affinity, which measures how much an atom wants to gain an electron. ∞ (Sections 7.4 and 7.5) Electron transfer to form oppositely charged ions occurs when one atom readily gives up an electron (low ionization energy) and another atom readily gains an electron (high electron affinity). Thus, NaCl is a typical ionic compound because it consists of a metal of low ionization energy and a nonmetal of high electron affinity. Using Lewis electron-dot symbols (and showing a chlorine atom rather than the Cl₂ molecule), we can represent this reaction as

$$Na + \dot{C} : \longrightarrow Na^+ + [\ddot{C} :]^-$$
 [8.2]

Do you expect a similar reaction between potassium metal and elemental bromine?

▲ Figure 8.2 Reaction of sodium metal with chlorine gas to form the ionic compound sodium chloride.

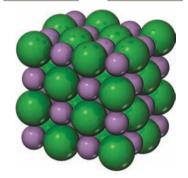

GO FIGURE

If no color key were provided, how would you know which color ball represented Na⁺ and which represented Cl⁻?

Each Na⁺ ion surrounded by six Cl⁻ ions Each Cl⁻ ion surrounded by six Na⁺ ions

▲ Figure 8.3 The crystal structure of sodium chloride.

The arrow indicates the transfer of an electron from the Na atom to the Cl atom. Each ion has an octet of electrons, the Na⁺ octet being the $2s^22p^6$ electrons that lie below the single 3s valence electron of the Na atom. We have put a bracket around the chloride ion to emphasize that all eight electrons are located on it.

Give It Some Thought

Describe the electron transfers that occur in the formation of calcium fluoride from elemental calcium and elemental fluorine.

Ionic substances possess several characteristic properties. They are usually brittle substances with high melting points. They are usually crystalline. Furthermore, ionic crystals often can be cleaved; that is, they break apart along smooth, flat surfaces. These characteristics result from electrostatic forces that maintain the ions in a rigid, well-defined, three-dimensional arrangement such as that shown in Figure 8.3.

Energetics of Ionic Bond Formation

The formation of sodium chloride from sodium and chlorine is *very* exothermic, as indicated by the large negative enthalpy of formation value given in Equation 8.1, $\Delta H_f^{\circ} = -410.9$ kJ. Appendix C shows that the heat of formation of other ionic substances is also quite negative. What factors make the formation of ionic compounds so exothermic?

In Equation 8.2 we represented the formation of NaCl as the transfer of an electron from Na to Cl. Recall from Section 7.4 that the loss of electrons from an atom is always an endothermic process. Removing an electron from Na(g) to form Na⁺(g) for instance, requires 496 kJ/mol. Recall from Section 7.5 that when a nonmetal gains an electron, the process is generally exothermic, as seen from the negative electron affinities of the elements. Adding an electron to Cl(g), for example, releases 349 kJ/mol. From the magnitudes of these energies, we can see that the transfer of an electron from a Na atom to a Cl atom would not be exothermic—the overall process would be an endothermic process that requires 496 - 349 = 147 kJ/mol. This endothermic process corresponds to the formation of sodium and chloride ions that are infinitely far apart—in other words, the positive energy change assumes that the ions do not interact with each other, which is quite different from the situation in ionic solids.

The principal reason ionic compounds are stable is the attraction between ions of opposite charge. This attraction draws the ions together, releasing energy and causing the ions to form a solid array, or lattice, such as that shown in Figure 8.3. A measure of how much stabilization results from arranging oppositely charged ions in an ionic solid is given by the **lattice energy**, which is *the energy required to completely separate one mole of a solid ionic compound into its gaseous ions*.

To envision this process for NaCl, imagine that the structure in Figure 8.3 expands from within, so that the distances between the ions increase until the ions are very far apart. This process requires $788 \, \text{kJ/mol}$, which is the value of the lattice energy:

$$NaCl(s) \longrightarrow Na^{+}(g) + Cl^{-}(g)$$
 $\Delta H_{lattice} = +788 \text{ kJ/mol}$ [8.3]

Notice that this process is highly endothermic. The reverse process—the coming together of Na⁺(g) and Cl⁻(g) to form NaCl(s)—is therefore highly exothermic ($\Delta H = -788 \, \text{kJ/mol}$).

▶ Table 8.2 lists the lattice energies for a number of ionic compounds. The large positive values indicate that the ions are strongly attracted to one another in ionic solids. The energy released by the attraction between ions of unlike charge more than makes up for the endothermic nature of ionization energies, making the formation of ionic compounds an exothermic process. The strong attractions also cause most ionic materials to be hard and brittle with high melting points—for example, NaCl melts at 801 °C.

Table 8.2	lattice Energies	for Some	Ionic Compounds

Compound	Lattice Energy (kJ/mol)	Compound	Lattice Energy (kJ/mol)
LiF	1030	MgCl_2	2326
LiCl	834	$SrCl_2$	2127
LiI	730		
NaF	910	MgO	3795
NaCl	788	CaO	3414
NaBr	732	SrO	3217
NaI	682		
KF	808	ScN	7547
KCl	701		
KBr	671		
CsCl	657		
CsI	600		

Give It Some Thought

If you were to perform the reaction $KCI(s) \longrightarrow K^{+}(g) + CI^{-}(g)$, would energy be released?

The magnitude of the lattice energy of an ionic solid depends on the charges of the ions, their sizes, and their arrangement in the solid. We saw in Section 5.1 that the electrostatic potential energy of two interacting charged particles is given by

$$E_{\rm el} = \frac{\kappa Q_1 Q_2}{d} \tag{8.4}$$

In this equation Q_1 and Q_2 are the charges on the particles in Coulombs, with their signs; d is the distance between their centers in meters, and κ is a constant, 8.99×10^9 J-m/C². Equation 8.4 indicates that the attractive interaction between two oppositely charged ions increases as the magnitudes of their charges increase and as the distance between their centers decreases. Thus, for a given arrangement of ions, the lattice energy increases as the charges on the ions increase and as their radii decrease. The variation in the magnitude of lattice energies depends more on ionic charge than on ionic radius because ionic radii vary over only a limited range compared to charges.

SAMPLE EXERCISE 8.1 Magnitudes of Lattice Energies

Without consulting Table 8.2, arrange the ionic compounds NaF, CsI, and CaO in order of increasing lattice energy.

SOLUTION

Analyze From the formulas for three ionic compounds, we must determine their relative lattice energies.

Plan We need to determine the charges and relative sizes of the ions in the compounds. We then use Equation 8.4 qualitatively to determine the relative energies, knowing that (a) the larger the ionic charges, the greater the energy and (b) the farther apart the ions are, the lower the energy.

Solve NaF consists of Na⁺ and F⁻ ions, CsI of Cs⁺ and I⁻ ions, and CaO of Ca²⁺ and O²⁻ ions. Because the product Q_1Q_2 appears in the numerator of Equation 8.4, the lattice energy increases dramatically when the charges increase. Thus, we expect the lattice energy of CaO, which has 2+ and 2- ions, to be the greatest of the three.

The ionic charges are the same in NaF and CsI. The difference in their lattice energies thus depends on the difference in the distance between ions in the lattice. Because ionic size increases as we go down a group in the periodic table ∞ (Section 7.3), we know that Cs^+ is larger than Na⁺ and I⁻ is larger than F⁻. Therefore, the distance between Na⁺ and F⁻ ions in NaF is less than the distance between the Cs^+ and I⁻ ions in CsI. As a result, the lattice energy of NaF should be greater than that of CsI. In order of increasing energy, therefore, we have CsI < NaF < CaO. **Check** Table 8.2 confirms our predicted order is correct.

Practice Exercise 1

Without looking at Table 8.2, predict which one of the following orderings of lattice energy is correct for these ionic compounds. (a) NaCl > MgO > CsI > ScN, (b) ScN > MgO > NaCl > CsI, (c) NaCl > CsI > ScN > CaO, (d) MgO > NaCl > ScN > CsI, (e) ScN > CsI > NaCl > MgO.

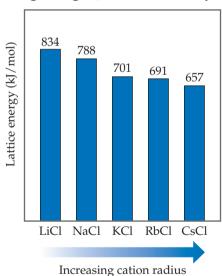

Practice Exercise 2

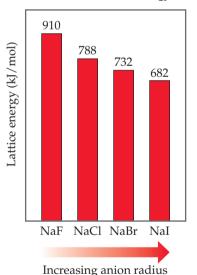

Which substance do you expect to have the greatest lattice energy: MgF₂, CaF₂, or ZrO₂?

Because lattice energy decreases as distance between ions increases, lattice energies follow trends that parallel those in ionic radius shown in Figure 7.8. In particular, because ionic radius increases as we go down a group of the periodic table, we find that, for a given type of ionic compound, lattice energy decreases as we go down a group. \blacktriangledown Figure 8.4 illustrates this trend for the alkali chlorides MCl (M = Li, Na, K, Rb, Cs) and the sodium halides NaX (X = F, Cl, Br, I).

▲ GO FIGURE

Using this figure, find the most likely range of values for the lattice energy of KF.

▲ Figure 8.4 Periodic trends in lattice energy as a function of cation or anion radius.

A Closer Look

Calculation of Lattice Energies: The Born-Haber Cycle

Lattice energies cannot be determined directly by experiment. They can, however, be calculated by envisioning the formation of an ionic compound as occurring in a series of well-defined steps. We can then use Hess's law (Section 5.6) to combine the steps in a way that gives the lattice energy for the compound. By so doing, we construct a Born–Haber cycle, a thermochemical cycle named after the German scientists Max Born (1882–1970) and Fritz Haber (1868–1934), who introduced it to analyze the factors contributing to the stability of ionic compounds.

Let's use NaCl as an example. In Equation 8.3, which defines lattice energy, NaCl(s) is the reactant, and the gas-phase ions Na $^+$ (g) and Cl $^-$ (g) are the products. This equation is our target as we apply Hess's Law.

In seeking a set of other equations that can be added up to give our target equation, we can use the heat of formation for NaCl ∞ (Section 5.7):

$$\operatorname{Na}(s) + \frac{1}{2}\operatorname{Cl}_2(g) \longrightarrow \operatorname{NaCl}(s) \qquad \Delta H_f^{\circ}[\operatorname{NaCl}(s)] = -411 \,\mathrm{kJ} \,[8.5]$$

Of course, we will have to turn this equation around so we have NaCl(*s*) as the reactant as we do in the equation for the lattice energy. We can use two other equations to arrive at our target, as shown below:

1.
$$\operatorname{NaCl}(s) \longrightarrow \operatorname{Na}(s) + \frac{1}{2}\operatorname{Cl}_2(g)$$
 $\Delta H_1 = -\Delta H_f^{\circ}[\operatorname{NaCl}(s)]$
 $= +411 \text{ kJ}$
2. $\operatorname{Na}(s) \longrightarrow \operatorname{Na}^+(g)$ $\Delta H_2 = ??$
3. $\frac{1}{2}\operatorname{Cl}_2(g) \longrightarrow \operatorname{Cl}^-(g)$ $\Delta H_3 = ???$
4. $\operatorname{NaCl}(s) \longrightarrow \operatorname{Na}^+(g) + \operatorname{Cl}^-(g)$ $\Delta H_4 = \Delta H_1 + \Delta H_2 + \Delta H_3$

Step 2 involves the formation of sodium ion from solid sodium, which is just the heat of formation for sodium gas and the first ionization energy for sodium (Appendix C and Figure 7.10 list numbers for these processes):

 $= \Delta H_{\text{lattice}}$

$$Na(s) \longrightarrow Na(g)$$
 $\Delta H = \Delta H_f^{\circ}[Na(g)] = 108 \text{ kJ}$ [8.6]
 $Na(g) \longrightarrow Na^+(g) + e^ \Delta H = I_1(Na) = 496 \text{ kJ}$ [8.7]

The sum of these two processes gives us the required energy for Step 2 (above), which is 604 kJ.

Similarly, for Step 3, we have to create chlorine atoms, and then anions, from the Cl₂ molecule, in two steps. The enthalpy changes for these two steps are the sum of the enthalpy of formation of Cl(g) and the electron affinity of chlorine, *E*(Cl):

$$\frac{1}{2}\operatorname{Cl}_{2}(g) \longrightarrow \operatorname{Cl}(g) \qquad \Delta H = \Delta H_{f}^{\circ}[\operatorname{Cl}(g)] = 122 \,\mathrm{kJ} \quad [8.8]$$

$$e^{-} + \operatorname{Cl}(g) \longrightarrow \operatorname{Cl}^{-}(g) \qquad \Delta H = E(\operatorname{Cl}) = -349 \,\mathrm{kJ} \quad [8.9]$$

The sum of these two processes gives us the required energy for Step 3 (above), which is -227 kJ.

Finally, when we put it all together, we have:

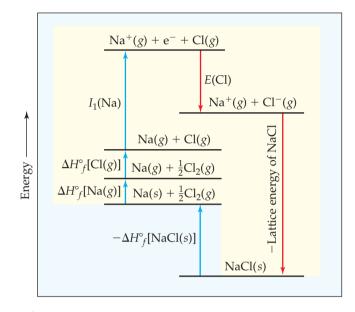

1. NaCl(s)
$$\longrightarrow$$
 Na(s) + $\frac{1}{2}$ Cl₂(g) $\Delta H_1 = -\Delta H_f^{\circ}[\text{NaCl}(s)]$
= + 411 kJ

2.
$$Na(s) \longrightarrow Na^+(g)$$
 $\Delta H_2 = 604 \text{ kJ}$

3.
$$\frac{1}{2} \operatorname{Cl}_2(g) \longrightarrow \operatorname{Cl}^-(g)$$
 $\Delta H_3 = -227 \text{ kJ}$
4. $\operatorname{NaCl}(s) \longrightarrow \operatorname{Na}^+(g) + \operatorname{Cl}^-(g)$ $\Delta H_4 = 788 \text{ kJ} = \Delta H_{\text{lattice}}$

This process is described as a "cycle" because it corresponds to the scheme in **Trigure 8.5**, which shows how all the quantities we have just calculated are related. The sum of all the blue "up" arrow energies has to be equal to the sum of all the red "down" arrow energies in this cycle. Born and Haber recognized that if we know the value of every quantity in the cycle except the lattice energy, we can calculate it from this cycle.

Related Exercises: 8.28, 8.29, 8.30, 8.83, 8.102, 8.103

▲ Figure 8.5 Born–Haber cycle for formation of NaCl. This Hess's law representation shows the energetic relationships in the formation of the ionic solid from its elements.

Electron Configurations of Ions of the s- and p-Block Elements

The energetics of ionic bond formation helps explain why many ions tend to have noble-gas electron configurations. For example, sodium readily loses one electron to form Na⁺, which has the same electron configuration as Ne:

Na
$$1s^2 2s^2 2p^6 3s^1 = [Ne] 3s^1$$

Na⁺ $1s^2 2s^2 2p^6 = [Ne]$

Even though lattice energy increases with increasing ionic charge, we never find ionic compounds that contain Na^{2+} ions. The second electron removed would have to come from an inner shell of the sodium atom, and removing electrons from an inner shell requires a very large amount of energy. ∞ (Section 7.4) The increase in lattice energy is not enough to compensate for the energy needed to remove an inner-shell electron. Thus, sodium and the other group 1A metals are found in ionic substances only as 1+ ions.

Similarly, adding electrons to nonmetals is either exothermic or only slightly endothermic as long as the electrons are added to the valence shell. Thus, a Cl atom easily adds an electron to form Cl⁻, which has the same electron configuration as Ar:

Cl
$$1s^2 2s^2 2p^6 3s^2 3p^5 = [\text{Ne}] 3s^2 3p^5$$

Cl $1s^2 2s^2 2p^6 3s^2 3p^6 = [\text{Ne}] 3s^2 3p^6 = [\text{Ar}]$

To form a Cl²⁻ ion, the second electron would have to be added to the next higher shell of the Cl atom, an addition that is energetically very unfavorable. Therefore, we

never observe Cl^{2-} ions in ionic compounds. We thus expect ionic compounds of the representative metals from groups 1A, 2A, and 3A to contain 1+, 2+ and 3+ cations, respectively, and usually expect ionic compounds of the representative nonmetals of groups 5A, 6A, and 7A to contain 3-, 2-, and 1- anions, respectively.

SAMPLE EXERCISE 8.2

Charges on Ions

Predict the ion generally formed by (a) Sr, (b) S, (c) Al.

SOLUTION

Analyze We must decide how many electrons are most likely to be gained or lost by atoms of Sr, S, and Al.

Plan In each case we can use the element's position in the periodic table to predict whether the element forms a cation or an anion. We can then use its electron configuration to determine the most likely ion formed.

Solve

- (a) Strontium is a metal in group 2A and therefore forms a cation. Its electron configuration is $[Kr]5s^2$, and so we expect that the two valence electrons will be lost to give an Sr^{2+} ion.
- (b) Sulfur is a nonmetal in group 6A and will thus tend to be found as an anion. Its electron configuration ([Ne] $3s^23p^4$) is two electrons short of a noble-gas configuration. Thus, we expect that sulfur will form S^2 ions.

(c) Aluminum is a metal in group 3A. We therefore expect it to form Al³⁺ ions.

Check The ionic charges we predict here are confirmed in Tables 2.4 and 2.5

Practice Exercise 1

Which of these elements is most likely to form ions with a 2+ charge?

(a) Li, (b) Ca, (c) O, (d) P, (e) Cl.

Practice Exercise 2

Predict the charges on the ions formed when magnesium reacts with nitrogen.

Transition Metal Ions

Because ionization energies increase rapidly for each successive electron removed, the lattice energies of ionic compounds are generally large enough to compensate for the loss of up to only three electrons from atoms. Thus, we find cations with charges of 1+, 2+, or 3+ in ionic compounds. Most transition metals, however, have more than three electrons beyond a noble-gas core. Silver, for example, has a $[Kr]4d^{10}5s^1$ electron configuration. Metals of group 1B (Cu, Ag, Au) often occur as 1+ ions (as in CuBr and AgCl). In forming Ag $^+$, the 5s electron is lost, leaving a completely filled 4d subshell. As in this example, transition metals generally do not form ions that have a noble-gas configuration. The octet rule, although useful, is clearly limited in scope.

Recall from Section 7.4 that when a positive ion forms from an atom, electrons are always lost first from the subshell having the largest value of n. Thus, in forming ions, transition metals lose the valence-shell s electrons first, then as many d electrons as required to reach the charge of the ion. For instance, in forming Fe^{2+} from Fe, which has the electron configuration $[Ar]3d^64s^2$, the two 4s electrons are lost, leading to an $[Ar]3d^6$ configuration. Removal of an additional electron gives Fe^{3+} , whose electron configuration is $[Ar]3d^5$.

Give It Some Thought

Which element forms a 3+ ion that has the electron configuration [Kr] $4d^6$?

8.3 | Covalent Bonding

The vast majority of chemical substances do not have the characteristics of ionic materials. Most of the substances with which we come into daily contact—such as water—tend to be gases, liquids, or solids with low melting points. Many, such as gasoline, vaporize readily. Many are pliable in their solid forms—for example, plastic bags and wax.

For the very large class of substances that do not behave like ionic substances, we need a different model to describe the bonding between atoms. G. N. Lewis reasoned that atoms might acquire a noble-gas electron configuration by sharing electrons with other atoms. A chemical bond formed by sharing a pair of electrons is a *covalent bond*.

The hydrogen molecule, H_2 , provides the simplest example of a covalent bond. When two hydrogen atoms are close to each other, the two positively charged nuclei repel each other, the two negatively charged electrons repel each other, and the nuclei and electrons attract each other, as shown in \triangleright Figure 8.6(a). Because the molecule is stable, we know that the attractive forces must overcome the repulsive ones. Let's take a closer look at the attractive forces that hold this molecule together.

By using quantum mechanical methods analogous to those used for atoms in Section 6.5, we can calculate the distribution of electron density in molecules. Such a calculation for H_2 shows that the attractions between the nuclei and the electrons cause electron density to concentrate between the nuclei, as shown in Figure 8.6(**b**). As a result, the overall electrostatic interactions are attractive. Thus, the atoms in H_2 are held together principally because the two positive nuclei are attracted to the concentration of negative charge between them. In essence, the shared pair of electrons in any covalent bond acts as a kind of "glue" to bind atoms together.

Give It Some Thought

lonizing an H_2 molecule to H_2^+ changes the strength of the bond. Based on the description of covalent bonding given previously, do you expect the H—H bond in H_2^+ to be weaker or stronger than the H—H bond in H_2 ?

Lewis Structures

The formation of covalent bonds can be represented with Lewis symbols. The formation of the H₂ molecule from two H atoms, for example, can be represented as

$$H \cdot + \cdot H \longrightarrow H : H$$

In forming the covalent bond, each hydrogen atom acquires a second electron, achieving the stable, two-electron, noble-gas electron configuration of helium.

Formation of a covalent bond between two Cl atoms to give a Cl_2 molecule can be represented in a similar way:

$$: \ddot{\mathbb{C}} \mathbf{i} \cdot + \cdot \ddot{\mathbb{C}} \mathbf{i} : \longrightarrow (\ddot{\mathbb{C}} \mathbf{i} \dot{\mathbb{C}} \dot{\mathbb{C}} \mathbf{i})$$

By sharing the bonding electron pair, each chlorine atom has eight electrons (an octet) in its valence shell, thus achieving the noble-gas electron configuration of argon.

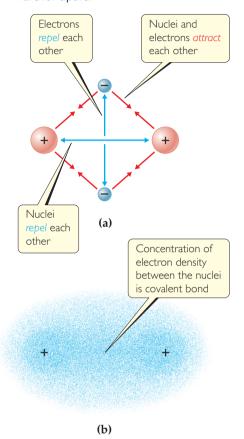

The structures shown here for H_2 and Cl_2 are **Lewis structures**, or *Lewis dot structures*. While these structures show circles to indicate electron sharing, the more common convention is to show each shared electron pair as a line and any unshared electron pairs (also called **lone pairs** or **nonbonding pairs**) as dots. Written this way, the Lewis structures for H_2 and Cl_2 are

For nonmetals, the number of valence electrons in a neutral atom is the same as the group number. Therefore, one might predict that 7A elements, such as F, would form one covalent bond to achieve an octet; 6A elements, such as O, would form two covalent bonds; 5A elements, such as N, would form three; and 4A elements, such as C, would form four. These predictions are borne out in many compounds, as in, for example, the compounds with hydrogen of the nonmetals of the second row of the periodic table:

GO FIGURE

What would happen to the magnitudes of the attractions and repulsions represented in (a) if the nuclei were farther apart?

▲ Figure 8.6 The covalent bond in H₂.
(a) The attractions and repulsions among electrons and nuclei in the hydrogen molecule. (b) Electron distribution in the H₂ molecule.

SAMPLE EXERCISE 8.3 Lewis Structure of a Compound

Given the Lewis symbols for nitrogen and fluorine in Table 8.1, predict the formula of the stable binary compound (a compound composed of two elements) formed when nitrogen reacts with fluorine and draw its Lewis structure.

SOLUTION

Analyze The Lewis symbols for nitrogen and fluorine reveal that nitrogen has five valence electrons and fluorine has seven.

Plan We need to find a combination of the two elements that results in an octet of electrons around each atom. Nitrogen requires three additional electrons to complete its octet, and fluorine requires one. Sharing a pair of electrons between one N atom and one F atom will result in an octet of electrons for fluorine but not for nitrogen. We therefore need to figure out a way to get two more electrons for the N atom.

Solve Nitrogen must share a pair of electrons with three fluorine atoms to complete its octet. Thus, the binary compound these two elements form must be NF_3 :

$$\begin{array}{cccc} \cdot \ddot{\mathbf{N}} \cdot + 3 \cdot \ddot{\mathbf{F}} \colon & \longrightarrow & : \ddot{\mathbf{F}} : \ddot{\mathbf{N}} : \ddot{\mathbf{F}} \colon & \longrightarrow & : \ddot{\mathbf{F}} - \ddot{\mathbf{N}} - \ddot{\mathbf{F}} \colon \\ \vdots \ddot{\mathbf{F}} \colon & \vdots \ddot{\mathbf{F}} \colon & \vdots \ddot{\mathbf{F}} \colon & \vdots \ddot{\mathbf{F}} : \end{array}$$

Check The Lewis structure in the center shows that each atom is surrounded by an octet of electrons. Once you are accustomed to thinking of each line in a Lewis structure as representing *two* electrons, you can just as easily use the structure on the right to check for octets.

Practice Exercise 1

Which of these molecules has the same number of shared electron pairs as unshared electron pairs? (a) HCl, (b) H_2S , (c) PF_3 , (d) CCl_2F_2 (e) Br_2 .

Practice Exercise 2

Compare the Lewis symbol for neon with the Lewis structure for methane, CH₄. How many valence electrons are in each structure? How many bonding pairs and how many nonbonding pairs does each structure have?

Multiple Bonds

A shared electron pair constitutes a single covalent bond, generally referred to simply as a **single bond**. In many molecules, atoms attain complete octets by sharing more than one pair of electrons. When two electron pairs are shared by two atoms, two lines are drawn in the Lewis structure, representing a **double bond**. In carbon dioxide, for example, bonding occurs between carbon, with four valence electrons, and oxygen, with six:

As the diagram shows, each oxygen atom acquires an octet by sharing two electron pairs with carbon. In the case of CO_2 , carbon acquires an octet by sharing two electron pairs with each of the two oxygen atoms; each double bond involves four electrons.

A **triple bond** corresponds to the sharing of three pairs of electrons, such as in the N_2 molecule:

$$:\dot{N}\cdot+\dot{N}:\longrightarrow:N:::N:$$
 (or:N \equiv N:)

Because each nitrogen atom has five valence electrons, three electron pairs must be shared to achieve the octet configuration.

The properties of N_2 are in complete accord with its Lewis structure. Nitrogen is a diatomic gas with exceptionally low reactivity that results from the very stable nitrogen–nitrogen bond. The nitrogen atoms are separated by only 1.10 Å. The short separation distance between the two N atoms is a result of the triple bond between the atoms. From studies of the structures of many different substances in which

nitrogen atoms share one or two electron pairs, we have learned that the average distance between bonded nitrogen atoms varies with the number of shared electron pairs:

As a general rule, the length of the bond between two atoms decreases as the number of shared electron pairs increases.

Give It Some Thought

The C-0 bond length in carbon monoxide, CO, is 1.13 Å, whereas the C-0 bond length in CO₂ is 1.24 Å. Without drawing a Lewis structure, do you think that CO contains a single, double, or triple bond?

8.4 | Bond Polarity and Electronegativity

When two identical atoms bond, as in Cl₂ or H₂, the electron pairs must be shared equally. When two atoms from opposite sides of the periodic table bond, such as NaCl, there is relatively little sharing of electrons, which means that NaCl is best described as an ionic compound composed of Na⁺ and Cl⁻ ions. The 3s electron of the Na atom is, in effect, transferred completely to chlorine. The bonds that are found in most substances fall somewhere between these extremes.

Bond polarity is a measure of how equally or unequally the electrons in any covalent bond are shared. A **nonpolar covalent bond** is one in which the electrons are shared equally, as in Cl_2 and N_2 . In a **polar covalent bond**, one of the atoms exerts a greater attraction for the bonding electrons than the other. If the difference in relative ability to attract electrons is large enough, an ionic bond is formed.

Electronegativity

We use a quantity called electronegativity to estimate whether a given bond is nonpolar covalent, polar covalent, or ionic. **Electronegativity** is defined as the ability of an atom *in a molecule* to attract electrons to itself. The greater an atom's electronegativity, the greater its ability to attract electrons to itself. The electronegativity of an atom in a molecule is related to the atom's ionization energy and electron affinity, which are properties of isolated atoms. An atom with a very negative electron affinity and a high ionization energy both attracts electrons from other atoms and resists having its electrons attracted away; therefore it is highly electronegative.

Electronegativity values can be based on a variety of properties, not just ionization energy and electron affinity. The American chemist Linus Pauling (1901–1994) developed the first and most widely used electronegativity scale, which is based on thermochemical data. As **Figure 8.7** shows, there is generally an increase in electronegativity from left to right across a period—that is, from the most metallic to the most nonmetallic elements. With some exceptions (especially in the transition metals), electronegativity decreases with increasing atomic number in a group. This is what we expect because we know that ionization energies decrease with increasing atomic number in a group and electron affinities do not change very much.

You do not need to memorize electronegativity values. Instead, you should know the periodic trends so that you can predict which of two elements is more electronegative.

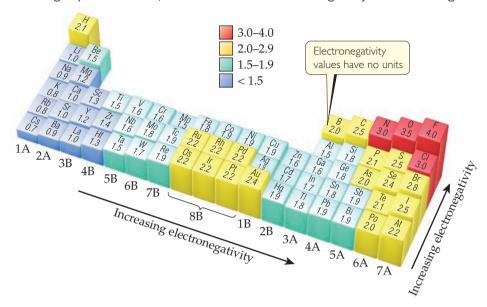

Give It Some Thought

How does the *electronegativity* of an element differ from its *electron affinity*?

GO FIGURE

For the group 6A elements, what is the trend in electronegativity with increasing atomic number?

▲ Figure 8.7 Electronegativity values based on Pauling's thermochemical data.

Electronegativity and Bond Polarity

We can use the difference in electronegativity between two atoms to gauge the polarity of the bond the atoms form. Consider these three fluorine-containing compounds:

	F_2	HF	LiF
Electronegativity difference	4.0 - 4.0 = 0	4.0 - 2.1 = 1.9	4.0 - 1.0 = 3.0
Type of bond	Nonpolar covalent	Polar covalent	Ionic

In F₂ the electrons are shared equally between the fluorine atoms and, thus, the covalent bond is *nonpolar*. A nonpolar covalent bond results when the electronegativities of the bonded atoms are equal.

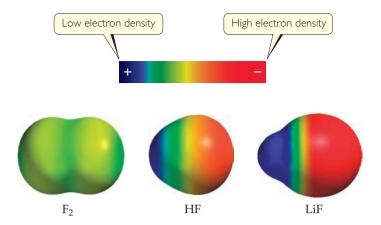

In HF the fluorine atom has a greater electronegativity than the hydrogen atom, with the result that the electrons are shared unequally—the bond is *polar*. In general, a polar covalent bond results when the atoms differ in electronegativity. In HF the more electronegative fluorine atom attracts electron density away from the less electronegative hydrogen atom, leaving a partial positive charge on the hydrogen atom and a partial negative charge on the fluorine atom. We can represent this charge distribution as

$$\delta$$
+ δ -
H — F

The $\delta+$ and $\delta-$ (read "delta plus" and "delta minus") symbolize the partial positive and negative charges, respectively. In a polar bond, these numbers are less than the full charges of the ions.

In LiF the electronegativity difference is very large, meaning that the electron density is shifted far toward F. The resultant bond is therefore most accurately described as *ionic*. Thus, if we considered the bond in LiF to be fully ionic, we could say δ + for Li is 1+ and δ - for F is 1-.

The shift of electron density toward the more electronegative atom in a bond can be seen from the results of calculations of electron-density distributions. For the three species in our example, the calculated electron-density distributions are shown in

▼Figure 8.8 Electron-density distribution. This computer-generated rendering shows the calculated electron-density distribution on the surface of the F₂, HF, and LiF molecules.

▲ Figure 8.8. You can see that in F_2 the distribution is symmetrical, in HF the electron density is clearly shifted toward fluorine, and in LiF the shift is even greater. These examples illustrate, therefore, that the greater the difference in electronegativity between two atoms, the more polar their bond.

Give It Some Thought

Based on differences in electronegativity, how would you characterize the bonding in sulfur dioxide, SO₂? Do you expect the bonds between S and O to be nonpolar, polar covalent, or ionic?

SAMPLE EXERCISE 8.4 Bond Polarity

In each case, which bond is more polar? (a) B—Cl or C—Cl, (b) P—F or P—Cl. Indicate in each case which atom has the partial negative charge.

SOLUTION

Analyze We are asked to determine relative bond polarities, given nothing but the atoms involved in the bonds.

Plan Because we are not asked for quantitative answers, we can use the periodic table and our knowledge of electronegativity trends to answer the question.

Solve

- (a) The chlorine atom is common to both bonds. Therefore, we just need to compare the electronegativities of B and C. Because boron is to the left of carbon in the periodic table, we predict that boron has the lower electronegativity. Chlorine, being on the right side of the table, has high electronegativity. The more polar bond will be the one between the atoms with the biggest differences in electronegativity. Consequently, the B—Cl bond is more polar; the chlorine atom carries the partial negative charge because it has a higher electronegativity.
- (b) In this example phosphorus is common to both bonds, and so we just need to compare the electronegativities of F and Cl. Because fluorine is above chlorine in the periodic table, it should be more electronegative and will form the more polar bond with P. The

higher electronegativity of fluorine means that it will carry the partial negative charge.

Check

- (a) Using Figure 8.7: The difference in the electronegativities of chlorine and boron is 3.0 − 2.0 = 1.0; the difference between the electronegativities of chlorine and carbon is 3.0 − 2.5 = 0.5. Hence, the B Cl bond is more polar, as we had predicted.
- (b) Using Figure 8.7: The difference in the electronegativities of chlorine and phosphorus is 3.0 − 2.1 = 0.9; the difference between the electronegativities of fluorine and phosphorus is 4.0 − 2.1 = 1.9. Hence, the P F bond is more polar, as we had predicted.

Practice Exercise 1

Which of the following bonds is the most polar? (a) H — F, (b) H — I, (c) Se — F, (d) N — P, (e) Ga — Cl.

Practice Exercise 2

Which of the following bonds is most polar: S — Cl, S — Br, Se — Cl, or Se — Br?

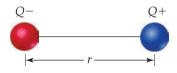

Dipole Moments

The difference in electronegativity between H and F leads to a polar covalent bond in the HF molecule. As a consequence, there is a concentration of negative charge on the more electronegative F atom, leaving the less electronegative H atom at the positive end

GO FIGURE

If the charged particles are moved closer together, does μ increase, decrease, or stay the same?

Dipole moment $\mu = Qr$

▲ Figure 8.9 Dipole and dipole moment. When charges of equal magnitude and opposite sign Q+ and Q- are separated by a distance r, a dipole is produced.

of the molecule. A molecule such as HF, in which the centers of positive and negative charge do not coincide, is a **polar molecule**. Thus, we describe both bonds and entire molecules as being polar and nonpolar.

We can indicate the polarity of the HF molecule in two ways:

$$\overset{\delta^{+}}{H} \overset{\delta^{-}}{-} \overset{\sigma^{-}}{F} \quad or \quad \overset{\longleftarrow}{H} \overset{\longleftarrow}{-} \overset{\Gamma}{F}$$

In the notation on the right, the arrow denotes the shift in electron density toward the fluorine atom. The crossed end of the arrow can be thought of as a plus sign designating the positive end of the molecule.

Polarity helps determine many properties we observe at the macroscopic level in the laboratory and in everyday life. Polar molecules align themselves with respect to one another, with the negative end of one molecule and the positive end of another attracting each other. Polar molecules are likewise attracted to ions. The negative end of a polar molecule is attracted to a positive ion, and the positive end is attracted to a negative ion. These interactions account for many properties of liquids, solids, and solutions, as you will see in Chapters 11, 12, and 13. Charge separation within molecules plays an important role in energy conversion processes such as photosynthesis (Chapter 23) and in organic solar cells (Chapter 12).

How can we quantify the polarity of a molecule? Whenever two electrical charges of equal magnitude but opposite sign are separated by a distance, a **dipole** is established. The quantitative measure of the magnitude of a dipole is called its **dipole moment**, denoted with the Greek letter mu, μ . If two equal and opposite charges Q+ and Q- are separated by a distance r, as in \P Figure 8.9, the magnitude of the dipole moment is the product of Q and r:

$$\mu = Qr \tag{8.10}$$

This expression tells us that dipole moment increases as the magnitude of Q increases and as r increases. The larger the dipole moment, the more polar the bond. For a nonpolar molecule, such as F_2 , the dipole moment is zero because there is no charge separation.

Give It Some Thought

Chlorine monofluoride, CIF, and iodine monofluoride, IF, are *interhalogen* compounds—compounds that contain bonds between different halogen elements. Which of these molecules has the larger dipole moment?

Dipole moments are experimentally measurable and are usually reported in *debyes* (D), a unit that equals 3.34×10^{-30} coulomb-meters (C-m). For molecules, we usually measure charge in units of the electronic charge e, 1.60×10^{-19} C, and distance in angstroms. This means we need to convert units whenever we want to report a dipole moment in debyes. Suppose that two charges 1+ and 1- (in units of e) are separated by 1.00 Å. The dipole moment produced is

$$\mu = Qr = (1.60 \times 10^{-19} \text{C})(1.00\text{Å}) \left(\frac{10^{-10} \text{ m}}{1\text{Å}}\right) \left(\frac{1 \text{ D}}{3.34 \times 10^{-30} \text{ C-m}}\right) = 4.79 \text{ D}$$

Measurement of the dipole moments can provide us with valuable information about the charge distributions in molecules, as illustrated in Sample Exercise 8.5.

SAMPLE EXERCISE 8.5

Dipole Moments of Diatomic Molecules

The bond length in the HCl molecule is 1.27 Å. (a) Calculate the dipole moment, in debyes, that results if the charges on the H and Cl atoms were 1+ and 1- respectively. (b) The experimentally measured dipole moment of HCl(g) is 1.08 D. What magnitude of charge, in units of e, on the H and Cl atoms leads to this dipole moment?

SOLUTION

Analyze and Plan We are asked in (a) to calculate the dipole moment of HCl that would result if there were a full charge transferred from H to Cl. We can use Equation 8.10 to obtain this result. In (b), we are given the actual dipole moment for the molecule and will use that value to calculate the actual partial charges on the H and Cl atoms.

Solve

(a) The charge on each atom is the electronic charge, $e = 1.60 \times 10^{-19}$ C. The separation is 1.27 Å. The dipole moment is therefore

$$\mu = \mathit{Qr} = (1.60 \times 10^{-19} \, \mathrm{C}) (1.27 \text{Å}) \bigg(\frac{10^{-10} \, \mathrm{m}}{1 \text{Å}} \bigg) \bigg(\frac{1 \, \mathrm{D}}{3.34 \times 10^{-30} \, \mathrm{C-m}} \bigg) = 6.08 \, \mathrm{D}$$

(b) We know the value of μ , 1.08 D, and the value of r, 1.27 Å. We want to calculate the value of Q:

$$Q = \frac{\mu}{r} = \frac{(1.08 \,\mathrm{D}) \bigg(\frac{3.34 \,\times\, 10^{-30} \,\mathrm{C}\text{-m}}{1 \,\mathrm{D}} \bigg)}{(1.27 \,\mathring{\mathrm{A}}\,) \bigg(\frac{10^{-10} \,\mathrm{m}}{1 \mathring{\mathrm{A}}} \bigg)} = 2.84 \,\times\, 10^{-20} \,\mathrm{C}$$

We can readily convert this charge to units of *e*:

Charge in
$$e = (2.84 \times 10^{-20} \,\mathrm{C}) \left(\frac{1e}{1.60 \times 10^{-19} \,\mathrm{C}} \right) = 0.178e$$

Thus, the experimental dipole moment indicates that the charge separation in the HCl molecule is

$$^{0.178\,+}_{
m H}$$
 — $^{0.178}_{
m Cl}$

Because the experimental dipole moment is less than that calculated in part (a), the charges on the atoms are much less than a full electronic charge. We could have anticipated this because the H—Cl bond is polar covalent rather than ionic.

Practice Exercise 1

Calculate the dipole moment for HF (bond length 0.917 Å), assuming that the bond is completely ionic. (a) 0.917 D, (b) 1.91 D, (c) 2.75 D, (d) 4.39 D, (e) 7.37 D

Practice Exercise 2

The dipole moment of chlorine monofluoride, ClF(g), is 0.88 D. The bond length of the molecule is 1.63 Å. (a) Which atom is expected to have the partial negative charge? (b) What is the charge on that atom in units of e?

▼ Table 8.3 presents the bond lengths and dipole moments of the hydrogen halides. Notice that as we proceed from HF to HI, the electronegativity difference decreases and the bond length increases. The first effect decreases the amount of charge separated and causes the dipole moment to decrease from HF to HI, even though the bond length is increasing. Calculations identical to those used in Sample Exercise 8.5 show that the charges on the atoms decrease from 0.41+ and 0.41− in HF to 0.057+ and 0.057− in HI. We can visualize the varying degree of electronic charge shift in these substances from computer-generated renderings based on calculations of electron distribution, as shown in Figure 8.10. For these molecules, the change in the electronegativity difference has a greater effect on the dipole moment than does the change in bond length.

Give It Some Thought

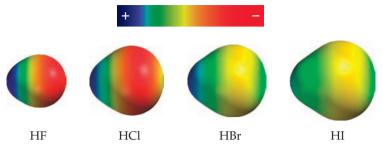

The bond between carbon and hydrogen is one of the most important types of bonds in chemistry. The length of an H-C bond is approximately 1.1 Å. Based on this distance and differences in electronegativity, do you expect the dipole moment of an individual H-C bond to be larger or smaller than that of an H-I bond?

Table 8.3 Bond Lengths, Electronegativity Differences, and Dipole Moments of the Hydrogen Halides

Compound	Bond Length (Å)	Electronegativity Difference	Dipole Moment (D)
HF	0.92	1.9	1.82
HCl	1.27	0.9	1.08
HBr	1.41	0.7	0.82
HI	1.61	0.4	0.44

GO FIGURE

How do you interpret the fact that there is no red in the HBr and HI representations?

▲ Figure 8.10 Charge separation in the hydrogen halides. In HF, the strongly electronegative F pulls much of the electron density away from H. In HI, the I, being much less electronegative than F, does not attract the shared electrons as strongly, and, consequently, there is far less polarization of the bond.

Before leaving this section, let's return to the LiF molecule in Figure 8.8. Under standard conditions, LiF exists as an ionic solid with an arrangement of atoms analogous to the sodium chloride structure shown in Figure 8.3. However, it is possible to generate LiF *molecules* by vaporizing the ionic solid at high temperature. The molecules have a dipole moment of 6.28 D and a bond distance of 1.53 Å. From these values we can calculate the charge on lithium and fluorine to be 0.857+ and 0.857—, respectively. This bond is extremely polar, and the presence of such large charges strongly favors the formation of an extended ionic lattice in which each lithium ion is surrounded by fluoride ions and vice versa. But even here, the experimentally determined charges on the ions are still not 1+ and 1—. This tells us that even in ionic compounds, there is still some covalent contribution to the bonding.

Differentiating Ionic and Covalent Bonding

To understand the interactions responsible for chemical bonding, it is advantageous to treat ionic and covalent bonding separately. That is the approach taken in this chapter, as well as in most other undergraduate-level chemistry texts. In reality, however, there is a continuum between the extremes of ionic and covalent bonding. This lack of a well-defined separation between the two types of bonding may seem unsettling or confusing at first.

The simple models of ionic and covalent bonding presented in this chapter go a long way toward understanding and predicting the structures and properties of chemical compounds. When covalent bonding is dominant, we expect compounds to exist as molecules,* having all the properties we associate with molecular substances, such as relatively low melting and boiling points and nonelectrolyte behavior when dissolved in water. When ionic bonding is dominant, we expect the compounds to be brittle, high-melting solids with extended lattice structures, exhibiting strong electrolyte behavior when dissolved in water.

Naturally, there are exceptions to these general characterizations, some of which we examine later in the book. Nonetheless, the ability to quickly categorize the predominant bonding interactions in a substance as covalent or ionic imparts considerable insight into the properties of that substance. The question then becomes the best way to recognize which type of bonding dominates.

^{*}There are some exceptions to this statement, such as network solids, including diamond, silicon, and germanium, where an extended structure is formed even though the bonding is clearly covalent. These examples are discussed in Section 12.7.

The simplest approach is to assume that the interaction between a metal and a nonmetal is ionic and that between two nonmetals is covalent. While this classification scheme is reasonably predictive, there are far too many exceptions to use it blindly. For example, tin is a metal and chlorine is a nonmetal, but $SnCl_4$ is a molecular substance that exists as a colorless liquid at room temperature. It freezes at $-33\,^{\circ}C$ and boils at 114 $^{\circ}C$. The characteristics of $SnCl_4$ are not those typical of an ionic substance. Is there a more predictable way of determining what type of bonding is prevalent in a compound? A more sophisticated approach is to use the difference in electronegativity as the main criterion for determining whether ionic or covalent bonding will be dominant. This approach correctly predicts the bonding in $SnCl_4$ to be polar covalent based on an electronegativity difference of 1.2 and at the same time correctly predicts the bonding in NaCl to be predominantly ionic based on an electronegativity difference of 2.1.

Evaluating bonding based on electronegativity difference is a useful system, but it has one shortcoming. The electronegativity values given in Figure 8.7 do not take into account changes in bonding that accompany changes in the oxidation state of the metal. For example, Figure 8.7 gives the electronegativity difference between manganese and oxygen as 3.5 - 1.5 = 2.0, which falls in the range where the bonding is normally considered ionic (the electronegativity difference for NaCl is 3.0 - 0.9 = 2.1). Therefore, it is not surprising to learn that manganese(II) oxide, MnO, is a green solid that melts at 1842 °C and has the same crystal structure as NaCl.

However, the bonding between manganese and oxygen is not always ionic. Manganese(VII) oxide, Mn_2O_7 , is a green liquid that freezes at 5.9 °C, an indication that covalent rather than ionic bonding dominates. The change in the oxidation state of manganese is responsible for the change in bonding. In general, as the oxidation state of a metal increases, so does the degree of covalent bonding. When the oxidation state of the metal is highly positive (roughly speaking, +4 or larger), we can expect significant covalency in the bonds it forms with nonmetals. Thus, metals in high oxidation states form molecular substances, such as Mn_2O_7 , or polyatomic ions, such as MnO_4^- and $CrO_4^{\ 2^-}$, rather than ionic compounds.

Give It Some Thought

You have a yellow solid that melts at 41° C and boils at 131° C and a green solid that melts at 2320° C. If you are told that one of them is Cr_2O_3 and the other is OsO_4 , which one do you expect to be the yellow solid?

8.5 | Drawing Lewis Structures

Lewis structures can help us understand the bonding in many compounds and are frequently used when discussing the properties of molecules. For this reason, drawing Lewis structures is an important skill that you should practice. Here is the procedure you should follow in drawing Lewis structures:

- 1. Sum the valence electrons from all atoms, taking into account overall charge. Use the periodic table to help you determine the number of valence electrons in each atom. For an anion, add one electron to the total for each negative charge. For a cation, subtract one electron from the total for each positive charge. Do not worry about keeping track of which electrons come from which atoms. Only the total number is important.
- 2. Write the symbols for the atoms, show which atoms are attached to which, and connect them with a single bond (a line, representing two electrons). Chemical formulas are often written in the order in which the atoms are connected in the molecule or ion. The formula HCN, for example, tells you that the carbon atom is bonded to the H and to the N. In many polyatomic molecules and

ions, the central atom is usually written first, as in ${\rm CO_3}^{2-}$ and ${\rm SF_4}$. Remember that the central atom is generally less electronegative than the atoms surrounding it. In other cases, you may need more information before you can draw the Lewis structure.

- **3.** Complete the octets around all the atoms bonded to the central atom. Keep in mind that a hydrogen atom has only a single pair of electrons around it.
- **4. Place any leftover electrons on the central atom,** even if doing so results in more than an octet of electrons around the atom.
- 5. If there are not enough electrons to give the central atom an octet, try multiple bonds. Use one or more of the unshared pairs of electrons on the atoms bonded to the central atom to form double or triple bonds.

The following examples of this procedure will help you put it into practice.

SAMPLE EXERCISE 8.6 Drawing a Lewis Structure

Draw the Lewis structure for phosphorus trichloride, PCl₃.

SOLUTION

Analyze and Plan We are asked to draw a Lewis structure from a molecular formula. Our plan is to follow the five-step procedure just described.

Solve First, we sum the valence electrons. Phosphorus (group 5A) has five valence electrons, and each chlorine (group 7A) has seven. The total number of valence electrons is therefore

$$5 + (3 \times 7) = 26$$

Second, we arrange the atoms to show which atom is connected to which, and we draw a single bond between them. There are various ways the atoms might be arranged. It helps to know, though, that in binary compounds the first element in the chemical formula is generally surrounded by the remaining atoms. So we proceed to draw a skeleton structure in which a single bond connects the P atom to each Cl atom:

(It is not crucial that the Cl atoms be to the left of, right of, and below the P atom—any structure that shows each of the three Cl atoms bonded to P will work.)

Third, we add Lewis electron dots to complete the octets on the atoms bonded to the central atom. Completing the octets around each Cl

atom accounts for 24 electrons (remember, each line in our structure represents *two* electrons):

Fourth, recalling that our total number of electrons is 26, we place the remaining two electrons on the central atom, P, which completes its octet:

This structure gives each atom an octet, so we stop at this point. (In checking for octets, remember to count a single bond as two electrons.)

Practice Exercise 1

Which of these molecules has a Lewis structure with a central atom having no nonbonding electron pairs? (a) CO_2 , (b) H_2S , (c) PF_3 , (d) SiF_4 , (e) more than one of a, b, c, d.

Practice Exercise 2

- (a) How many valence electrons should appear in the Lewis structure for CH₂Cl₂?
- (b) Draw the Lewis structure.

SAMPLE EXERCISE 8.7 Lewis Structure with a Multiple Bond

Draw the Lewis structure for HCN.

SOLUTION

Hydrogen has one valence electron, carbon (group 4A) has four, and nitrogen (group 5A) has five. The total number of valence electrons is, therefore, 1+4+5=10. In principle, there are different ways in which we might choose to arrange the atoms. Because hydrogen can accommodate only one electron pair, it always has only one single bond associated with it. Therefore, C-H-N is an impossible arrangement. The remaining two possibilities are H-C-N and H-N-C. The first is the arrangement found experimentally. You might have guessed this because (a) the formula is written with the

atoms in this order and (b) carbon is less electronegative than nitrogen. Thus, we begin with the skeleton structure

$$H-C-N$$

The two bonds account for four electrons. The H atom can have only two electrons associated with it, and so we will not add any more electrons to it. If we place the remaining six electrons around N to give it an octet, we do not achieve an octet on C:

We therefore try a double bond between C and N, using one of the unshared pairs we placed on N. Again we end up with fewer than eight electrons on C, and so we next try a triple bond. This structure gives an octet around both C and N:

$$H-C \xrightarrow{\checkmark} \dot{N}$$
: $\longrightarrow H-C \equiv N$:

The octet rule is satisfied for the C and N atoms, and the H atom has two electrons around it. This is a correct Lewis structure.

Practice Exercise 1

Draw the Lewis structure(s) for the molecule with the chemical formula C₂H₃N, where the N is connected to only one other atom. How many double bonds are there in the correct Lewis structure? (a) zero, (b) one, (c) two, (d) three, (e) four.

Practice Exercise 2

Draw the Lewis structure for (a) NO⁺ ion, (b) C₂H₄.

SAMPLE

EXERCISE 8.8 Lewis Structure for a Polyatomic Ion

Draw the Lewis structure for the BrO₃⁻ ion.

SOLUTION

Bromine (group 7A) has seven valence electrons, and oxygen (group 6A) has six. We must add one more electron to our sum to account for the 1 – charge of the ion. The total number of valence electrons is, therefore, $7 + (3 \times 6) + 1 = 26$. For oxyanions $-SO_4^{2-}$, NO_3^{-} , CO_3^{2-} , and so forth — the oxygen atoms surround the central nonmetal atom. After arranging the O atoms around the Br atom, drawing single bonds, and distributing the unshared electron pairs, we have

Notice that the Lewis structure for an ion is written in brackets and the charge is shown outside the brackets at the upper right.

Practice Exercise 1

How many nonbonding electron pairs are there in the Lewis structure of the peroxide ion, O_2^{2-} ? (a) 7, (b) 6, (c) 5, (d) 4, (e) 3.

Practice Exercise 2

Draw the Lewis structure for (a) ClO_2^- , (b) PO_4^{3-} .

Formal Charge and Alternative Lewis Structures

When we draw a Lewis structure, we are describing how the electrons are distributed in a molecule or polyatomic ion. In some instances we can draw two or more valid Lewis structures for a molecule that all obey the octet rule. All of these structures can be thought of as contributing to the actual arrangement of the electrons in the molecule, but not all of them will contribute to the same extent. How do we decide which one of several Lewis structures is the most important? One approach is to do some "bookkeeping" of the valence electrons to determine the *formal charge* of each atom in each Lewis structure. The formal charge of any atom in a molecule is the charge the atom would have if each bonding electron pair in the molecule were shared equally between its two atoms.

To calculate the formal charge on any atom in a Lewis structure, we assign electrons to the atom as follows:

- 1. All unshared (nonbonding) electrons are assigned to the atom on which they are
- 2. For any bond—single, double, or triple—half of the bonding electrons are assigned to each atom in the bond.

The formal charge of each atom is calculated by subtracting the number of electrons assigned to the atom from the number of valence electrons in the neutral atom:

Formal charge = valence electrons $-\frac{1}{2}$ (bonding electrons) – nonbonding electrons [8.11]

Let's practice by calculating the formal charges for the atoms in the cyanide ion, CN⁻, which has the Lewis structure

The neutral C atom has four valence electrons. There are six electrons in the cyanide triple bond and two nonbonding electrons on C. We calculate the formal charge on C as $4 - \frac{1}{2}(6) - 2 = -1$. For N, the valence electron count is five; there are six electrons in the cyanide triple bond, and two nonbonding electrons on the N. The formal charge on N is $5 - \frac{1}{2}(6) - 2 = 0$. We can draw the whole ion with its formal charges as

Notice that the sum of the formal charges equals the overall charge on the ion, 1—. The formal charges on a neutral molecule must add to zero, whereas those on an ion add to give the charge on the ion.

If we can draw several Lewis structures for a molecule, the concept of formal charge can help us decide which is the most important, which we shall call the *dominant* Lewis structure. One Lewis structure for CO_2 for instance, has two double bonds. However, we can also satisfy the octet rule by drawing a Lewis structure having one single bond and one triple bond. Calculating formal charges in these structures, we have

	Ö=	=C=	=Ö	:Ö-	-C	O:
Valence electrons:	6	4	6	6	4	6
–(Electrons assigned to atom):	6	4	6	7	4	5
Formal charge:	0	0	0	-1	0	+1

Note that in both cases the formal charges add up to zero, as they must because CO_2 is a neutral molecule. So, which is the more correct structure? As a general rule, when more than one Lewis structure is possible, we will use the following guidelines to choose the dominant one:

- 1. The dominant Lewis structure is generally the one in which the atoms bear formal charges closest to zero.
- **2.** A Lewis structure in which any negative charges reside on the more electronegative atoms is generally more dominant than one that has negative charges on the less electronegative atoms.

Thus, the first Lewis structure of CO_2 is the dominant one because the atoms carry no formal charges and so satisfy the first guideline. The other Lewis structure shown (and the similar one that has a triple bond to the left O and a single bond to the right O) contribute to the actual structure to a much smaller extent.

Although the concept of formal charge helps us to arrange alternative Lewis structures in order of importance, it is important that you remember that *formal charges do not represent real charges on atoms*. These charges are just a bookkeeping convention. The actual charge distributions in molecules and ions are determined not by formal charges but by a number of other factors, including electronegativity differences between atoms.

Give It Some Thought

Suppose a Lewis structure for a neutral fluorine-containing molecule results in a formal charge of +1 on the fluorine atom. What conclusion would you draw?

SAMPLE EXERCISE 8.9 Lewis Structures and Formal Charges

Three possible Lewis structures for the thiocyanate ion, NCS-, are

$$[: \ddot{\mathbb{N}} - C \equiv S:]^{-} \qquad [\ddot{\mathbb{N}} = C = \ddot{\mathbb{S}}]^{-} \qquad [: \mathbb{N} \equiv C - \ddot{\mathbb{S}}:]^{-}$$

- (a) Determine the formal charges in each structure.
- (b) Based on the formal charges, which Lewis structure is the dominant one?

SOLUTION

(a) Neutral N, C, and S atoms have five, four, and six valence electrons, respectively. We can determine the formal charges in the three structures by using the rules we just discussed:

As they must, the formal charges in all three structures sum to 1-, the overall charge of the ion.

(b) The dominant Lewis structure generally produces formal charges of the smallest magnitude (guideline 1). That eliminates the left structure as the dominant one. Further, as discussed in Section 8.4, N is more electronegative than C or S. Therefore, we expect any negative formal charge to reside on the N atom (guideline 2). For these two reasons, the middle Lewis structure is the dominant one for NCS⁻.

Practice Exercise 1

Phosphorus oxychloride has the chemical formula POCl₃, with P as the central atom. To minimize formal charge, how many bonds does phosphorus make to the other atoms in the molecule? (Count each single bond as one, each double bond as two, and each triple bond as three.)

(a) 3, (b) 4, (c) 5, (d) 6, (e) 7

Practice Exercise 2

The cyanate ion, NCO⁻, has three possible Lewis structures. (a) Draw these three structures and assign formal charges in each. (b) Which Lewis structure is dominant?

A Closer Look

Oxidation Numbers, Formal Charges, and Actual Partial Charges

In Chapter 4 we introduced the rules for assigning *oxidation numbers* to atoms. The concept of electronegativity is the basis of these numbers. An atom's oxidation number is the charge the atom would have if its bonds were completely ionic. That is, in determining oxidation number, all shared electrons are counted with the more electronegative atom. For example, consider the Lewis structure of HCl in \blacktriangledown Figure 8.11(a). To assign oxidation numbers, both electrons in the covalent bond between the atoms are assigned to the more electronegative Cl atom. This procedure gives Cl eight valence electrons, one more than in the neutral atom. Thus, its oxidation number is -1. Hydrogen has no valence electrons when they are counted this way, giving it an oxidation number of +1.

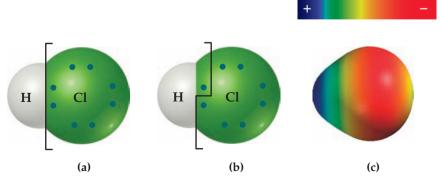

In assigning formal charges to the atoms in HCl [Figure 8.11(b)], we ignore electronegativity; the electrons in bonds are assigned equally to the two bonded atoms. In this case Cl has seven assigned electrons, the same as that of the neutral Cl atom, and H has one assigned electron. Thus, the formal charges of both Cl and H in this compound are 0.

Neither oxidation number nor formal charge gives an accurate depiction of the actual charges on atoms because oxidation numbers overstate the role of electronegativity and formal charges ignore it. It seems reasonable that electrons in covalent bonds should be apportioned according to the relative electronegativities of the bonded atoms. Figure 8.7

(page 310) shows that Cl has an electronegativity of 3.0, while the electronegativity value of H is 2.1. The more electronegative Cl atom might therefore be expected to have roughly 3.0/(3.0+2.1)=0.59 of the electrical charge in the bonding pair, whereas the H atom would have 2.1/(3.0+2.1)=0.41 of the charge. Because the bond consists of two electrons, the Cl atom's share is $0.59\times 2e=1.18e$, or 0.18e more than the neutral Cl atom. This gives rise to a partial negative charge of 0.18- on Cl and therefore a partial positive charge of 0.18+ on H. (Notice again that we place the plus and minus signs *before* the magnitude in writing oxidation numbers and formal charges but *after* the magnitude in writing actual charges.)

The dipole moment of HCl gives an experimental measure of the partial charge on each atom. In Sample Exercise 8.5 we saw that the dipole moment of HCl corresponds to a partial charge of 0.178+ on H and 0.178- on Cl, in remarkably good agreement with our simple approximation based on electronegativities. Although our approximation method provides ballpark numbers for the magnitude of charge on atoms, the relationship between electronegativities and charge separation is generally more complicated. As we have already seen, computer programs employing quantum mechanical principles have been developed to obtain more accurate estimates of the partial charges on atoms, even in complex molecules. A computer-graphical representation of the calculated charge distribution in HCl is shown in Figure 8.11(c).

Is the electron density consistent with equal contributions from the two resonance structures for O_3 ? Explain.

Primary color Primary color

▲ Figure 8.13 Resonance. Describing a molecule as a blend of different resonance structures is similar to describing a paint color as a blend of primary colors. (a) Green paint is a blend of blue and yellow. We cannot describe green as a single primary color. (b) The ozone molecule is a blend of two resonance structures. We cannot describe the ozone molecule in terms of a single Lewis structure.

8.6 | Resonance Structures

We sometimes encounter molecules and ions in which the experimentally determined arrangement of atoms is not adequately described by a single dominant Lewis structure. Consider ozone, O₃, which is a bent molecule with two equal O ─ O bond lengths (◀ Figure 8.12). Because each oxygen atom contributes 6 valence electrons, the ozone molecule has 18 valence electrons. This means the Lewis structure must have one O ─ O single bond and one O ─ O double bond to attain an octet about each atom:

However, this single structure cannot by itself be dominant because it requires that one O - O bond be different from the other, contrary to the observed structure—we would expect the O = O double bond to be shorter than the O - O single bond. ∞ (Section 8.3) In drawing the Lewis structure, however, we could just as easily have put the O = O bond on the left:

There is no reason for one of these Lewis structures to be dominant because they are equally valid representations of the molecule. The placement of the atoms in these two alternative but completely equivalent Lewis structures is the same, but the placement of the electrons is different; we call Lewis structures of this sort **resonance structures**. To describe the structure of ozone properly, we write both resonance structures and use a double-headed arrow to indicate that the real molecule is described by an average of the two:

$$0 \longrightarrow 0 \longrightarrow 0$$

To understand why certain molecules require more than one resonance structure, we can draw an analogy to mixing paint (◀ Figure 8.13). Blue and yellow are both primary colors of paint pigment. An equal blend of blue and yellow pigments produces green pigment. We cannot describe green paint in terms of a single primary color, yet it still has its own identity. Green paint does not oscillate between its two primary colors: It is not blue part of the time and yellow the rest of the time. Similarly, molecules such as ozone cannot be described as oscillating between the two individual Lewis structures shown previously—there are two equivalent dominant Lewis structures that contribute equally to the actual structure of the molecule.

The actual arrangement of the electrons in molecules such as O₃ must be considered as a blend of two (or more) Lewis structures. By analogy to the green paint, the molecule has its own identity separate from the individual resonance structures. For example, the ozone molecule always has two equivalent O—O bonds whose lengths are intermediate between the lengths of an oxygen–oxygen single bond and an oxygen–oxygen double bond. Another way of looking at it is to say that the rules for drawing Lewis structures do not allow us to have a single dominant structure for the ozone molecule. For example, there are no rules for drawing half-bonds. We can get around this limitation by drawing two equivalent Lewis structures that, when averaged, amount to something very much like what is observed experimentally.

Give It Some Thought

The O—O bonds in ozone are often described as "one-and-a-half" bonds. Is this description consistent with the idea of resonance?

As an additional example of resonance structures, consider the nitrate ion, NO₃⁻, for which three equivalent Lewis structures can be drawn:

$$\begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :\bigcirc: \\ | \\ | \\ :\bigcirc: \\ N \\ \bigcirc: \\ O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix} :O: \\ | \\ :O \end{bmatrix} \xrightarrow{-} \longleftrightarrow \begin{bmatrix}$$

Notice that the arrangement of atoms is the same in each structure—only the placement of electrons differs. In writing resonance structures, the same atoms must be bonded to each other in all structures, so that the only differences are in the arrangements of electrons. All three NO_3^- Lewis structures are equally dominant and taken together adequately describe the ion, in which all three N-O bond lengths are the same.

Give It Some Thought

In the same sense that we describe the 0-0 bonds in O_3 as "one-and-a-half" bonds, how would you describe the N-0 bonds in NO_3^{-2} ?

There are some molecules or ions for which all possible Lewis structures may not be equivalent; in other words, one or more resonance structures are more dominant than others. We will encounter examples of this as we proceed.

SAMPLE EXERCISE 8.10 Resonance Structures

Which is predicted to have the shorter sulfur-oxygen bonds, SO_3 or SO_3^{2-} ?

SOLUTION

The sulfur atom has six valence electrons, as does oxygen. Thus, SO₃ contains 24 valence electrons. In writing the Lewis structure, we see that three equivalent resonance structures can be drawn:

As with NO_3^- the actual structure of SO_3 is an equal blend of all three. Thus, each S-O bond length should be about one-third of the way between the length of a single bond and the length of a double bond. That is, S-O should be shorter than single bonds but not as short as double bonds.

The ${\rm SO_3}^{2-}$ ion has 26 electrons, which leads to a dominant Lewis structure in which all the S — O bonds are single:

$$\begin{bmatrix} : \ddot{\bigcirc} - \ddot{S} - \ddot{\bigcirc} : \\ : \dot{\bigcirc} : \end{bmatrix}^{2-}$$

Our analysis of the Lewis structures thus far leads us to conclude that SO_3 should have the shorter S - O bonds and SO_3^{2-} the longer ones. This conclusion is correct: The experimentally measured S - O bond lengths are 1.42 Å in SO_3 and 1.51 Å in SO_3^{2-} .

Practice Exercise 1

Which of these statements about resonance is true?

- (a) When you draw resonance structures, it is permissible to alter the way atoms are
- (b) The nitrate ion has one long N—O bond and two short N—O bonds.
- (c) "Resonance" refers to the idea that molecules are resonating rapidly between different bonding patterns.
- (d) The cyanide ion has only one dominant resonance structure.
- (e) All of the above are true.

Practice Exercise 2

Draw two equivalent resonance structures for the formate ion, HCO₂⁻.

GO FIGURE

What is the significance of the dashed bonds in this ball-and-stick model?

▲ Figure 8.14 Benzene, an "aromatic" organic compound. The benzene molecule is a regular hexagon of carbon atoms with a hydrogen atom bonded to each one. The dashed lines represent the blending of two equivalent resonance structures, leading to C—C bonds that are intermediate between single and double bonds.

Resonance in Benzene

Resonance is an important concept in describing the bonding in organic molecules, particularly *aromatic* organic molecules, a category that includes the hydrocarbon *benzene*, C_6H_6 . The six C atoms are bonded in a hexagonal ring, and one H atom is bonded to each C atom. We can write two equivalent dominant Lewis structures for benzene, each of which satisfies the octet rule. These two structures are in resonance:

Note that the double bonds are in different places in the two structures. Each of these resonance structures shows three carbon-carbon single bonds and three carbon-carbon double bonds. However, experimental data show that all six C—C bonds are of equal length, 1.40 Å, intermediate between the typical bond lengths for a C—C single bond (1.54 Å) and a C—C double bond (1.34 Å). Each of the C—C bonds in benzene can be thought of as a blend of a single bond and a double bond (\P Figure 8.14).

Benzene is commonly represented by omitting the hydrogen atoms and showing only the carbon–carbon framework with the vertices unlabeled. In this convention, the resonance in the molecule is represented either by two structures separated by a double-headed arrow or by a shorthand notation in which we draw a hexagon with a circle inside:

The shorthand notation reminds us that benzene is a blend of two resonance structures—it emphasizes that the C=C double bonds cannot be assigned to specific edges of the hexagon. Chemists use both representations of benzene interchangeably.

The bonding arrangement in benzene confers special stability to the molecule. As a result, millions of organic compounds contain the six-membered ring characteristic of benzene. Many of these compounds are important in biochemistry, in pharmaceuticals, and in the production of modern materials.

Give It Some Thought

Each Lewis structure of benzene has three C = C double bonds. Another hydrocarbon containing three C = C double bonds is *hexatriene*, C_6H_8 . A Lewis structure of hexatriene is

Do you expect hexatriene to have multiple resonance structures? If not, why is this molecule different from benzene with respect to resonance?

8.7 | Exceptions to the Octet Rule

The octet rule is so simple and useful in introducing the basic concepts of bonding that you might assume it is always obeyed. In Section 8.2, however, we noted its limitation in dealing with ionic compounds of the transition metals. The rule also fails in many

situations involving covalent bonding. These exceptions to the octet rule are of three main types:

- 1. Molecules and polyatomic ions containing an odd number of electrons
- 2. Molecules and polyatomic ions in which an atom has fewer than an octet of valence electrons
- 3. Molecules and polyatomic ions in which an atom has more than an octet of valence electrons

Odd Number of Electrons

In the vast majority of molecules and polyatomic ions, the total number of valence electrons is even, and complete pairing of electrons occurs. However, in a few molecules and polyatomic ions, such as ClO_2 , NO, NO_2 and O_2^- , the number of valence electrons is odd. Complete pairing of these electrons is impossible, and an octet around each atom cannot be achieved. For example, NO contains 5+6=11 valence electrons. The two most important Lewis structures for this molecule are

$$\ddot{N} = \ddot{O}$$
 and $\ddot{N} = \ddot{O}$

Give It Some Thought

Which of the Lewis structures for NO is dominant based on analysis of the formal charges?

Less Than an Octet of Valence Electrons

A second type of exception occurs when there are fewer than eight valence electrons around an atom in a molecule or polyatomic ion. This situation is also relatively rare (with the exception of hydrogen and helium as we have already discussed), most often encountered in compounds of boron and beryllium. As an example, let's consider boron trifluoride, BF₃. If we follow the first steps of our procedure for drawing Lewis structures, we obtain the structure

which has only six electrons around the boron atom. The formal charge is zero on both B and F, and we could complete the octet around boron by forming a double bond (recall that if there are not enough electrons to give the central atom an octet, a multiple bond may be the answer). In so doing, we see that there are three equivalent resonance structures (the formal charges are shown in red):

$$0 : F : \stackrel{+1}{\overset{}_{\stackrel{}{\overset{}}{\overset{}}{\overset{}}}} : F : \stackrel{0}{\overset{}{\overset{}}} : F : \stackrel{0}{\overset{}{\overset{}}} : F : \stackrel{0}{\overset{}} : F : \stackrel{0}$$

Each of these structures forces a fluorine atom to share additional electrons with the boron atom, which is inconsistent with the high electronegativity of fluorine. In fact, the formal charges tell us that this is an unfavorable situation. In each structure, the F atom involved in the B = F double bond has a formal charge of +1 while the less electronegative B atom has a formal charge of -1. Thus, the resonance structures containing a B = F double bond are less important than the one in which there are fewer than an octet of valence electrons around boron:

$$:\ddot{F}:\xrightarrow{B},\dot{F}:\longleftrightarrow\underbrace{\ddot{F}:\xrightarrow{B},\dot{F}:}\longleftrightarrow:\ddot{F}:\xrightarrow{\ddot{F}:}\underbrace{\ddot{F}:\xrightarrow{B}}_{\ddot{F}:}\longleftrightarrow:\ddot{F}:\xrightarrow{\ddot{B}}_{\ddot{F}:}$$

Dominant

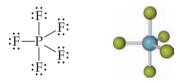

Less important

We usually represent BF₃ solely by the dominant resonance structure, in which there are only six valence electrons around boron. The chemical behavior of BF₃ is consistent with this representation. In particular, BF3 reacts energetically with molecules having an unshared pair of electrons that can be used to form a bond with boron, as, for example, in the reaction

In the stable compound NH₃BF₃, boron has an octet of valence electrons.

More Than an Octet of Valence Electrons

The third and largest class of exceptions consists of molecules or polyatomic ions in which there are more than eight electrons in the valence shell of an atom. When we draw the Lewis structure for PF5, for example, we are forced to place ten electrons around the central phosphorus atom:

Molecules and ions with more than an octet of electrons around the central atom are often called hypervalent. Other examples of hypervalent species are SF₄, AsF₆⁻, and ICl₄. The corresponding molecules with a second-period atom as the central atom, such as NCl₅ and OF₄, do not exist.

Hypervalent molecules are formed only for central atoms from period 3 and below in the periodic table. The principal reason for their formation is the relatively larger size of the central atom. For example, a P atom is large enough that five F (or even five Cl) atoms can be bonded to it without being too crowded. By contrast, an N atom is too small to accommodate five atoms bonded to it. Because size is a factor, hypervalent molecules occur most often when the central atom is bonded to the smallest and most electronegative atoms—F, Cl, and O.

The notion that a valence shell can contain more than eight electrons is also consistent with the presence of unfilled nd orbitals in atoms from period 3 and below. (Section 6.8) By comparison, in elements of the second period, only the 2s and 2p valence orbitals are available for bonding. However, theoretical work on the bonding in molecules such as PF₅ and SF₆ suggests that the presence of unfilled 3d orbitals in P and S has a relatively minor impact on the formation of hypervalent molecules. Most chemists now believe that the larger size of the atoms from periods 3 through 6 is more important to explain hypervalency than is the presence of unfilled *d* orbitals.

SAMPLE

EXERCISE 8.11 Lewis Structure for an Ion with More Than an Octet of Electrons

Draw the Lewis structure for ICl₄⁻.

SOLUTION

Iodine (group 7A) has seven valence electrons. Each chlorine atom (group 7A) also has seven. An extra electron is added to account for the 1 - charge of the ion. Therefore, the total number of valence electrons is $7 + (4 \times 7) + 1 = 36$.

The I atom is the central atom in the ion. Putting eight electrons around each Cl atom (including a pair of electrons between I and each Cl to represent the single bond between these atoms) requires $8 \times 4 = 32$ electrons.

We are thus left with 36 - 32 = 4 electrons to be placed on the larger iodine:

Iodine has 12 valence electrons around it, four more than needed for an octet.

Practice Exercise 1

In which of these molecules or ions is there only one lone pair of electrons on the central sulfur atom?

(a) SF_4 , (b) SF_6 , (c) SOF_4 , (d) SF_2 , (e) SO_4^{2-}

Practice Exercise 2

(a) Which of the following atoms is never found with more than an octet of valence electrons around it? S, C, P, Br, I. (b) Draw the Lewis structure for XeF₂.

Finally, there are Lewis structures where you might have to choose between satisfying the octet rule and obtaining the most favorable formal charges by using more than an octet of electrons. For example, consider these Lewis structures for the phosphate ion, $PO_4^{\ 3-}$:

$$\begin{bmatrix} : \ddot{O}: \\ : \ddot{O}: \\ -\ddot{I} \\ : \dot{O}: \end{bmatrix}^{-1} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \vdots \\ -\ddot{I} \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ 0 \\ \end{bmatrix}^{3-} = \begin{bmatrix} : \ddot{O}: \\ \ddot{O}: \\ \ddot{O}: \\ \ddot{O}: \end{matrix}^{3-} = \begin{bmatrix} :$$

The formal charges on the atoms are shown in red. In the left structure, the P atom obeys the octet rule. In the right structure, however, the P atom has five electron pairs, leading to smaller formal charges on the atoms. (You should be able to see that there are three additional resonance structures for the Lewis structure on the right.)

Chemists are still debating which of these two structures is dominant for $\mathrm{PO_4}^{3-}$. Recent theoretical calculations based on quantum mechanics suggest to some researchers that the left structure is the dominant one. Other researchers claim that the bond lengths in the ion are more consistent with the right structure being dominant. This disagreement is a convenient reminder that, in general, multiple Lewis structures can contribute to the actual electron distribution in an atom or molecule.

8.8 | Strengths and Lengths of Covalent Bonds

The stability of a molecule is related to the strengths of its covalent bonds. The strength of a covalent bond between two atoms is determined by the energy required to break the bond. It is easiest to relate bond strength to the enthalpy change in reactions in which bonds are broken. ∞ (Section 5.4) The **bond enthalpy** is the enthalpy change, ΔH , for the breaking of a particular bond in one mole of a gaseous substance. For example, the bond enthalpy for the bond in Cl_2 is the enthalpy change when 1 mol of $\text{Cl}_2(g)$ dissociates into chlorine atoms:

$$\ddot{\text{Ci}} - \ddot{\text{Ci}} \cdot (g) \longrightarrow 2 \ddot{\text{Ci}} \cdot (g)$$

We use the letter D followed by the bond in question to represent bond enthalpies. Thus, for example, D(Cl-Cl) is the bond enthalpy for the Cl_2 bond, and D(H-Br) is the bond enthalpy for the HBr bond.

It is relatively simple to assign bond enthalpies to the bond in a diatomic molecule because in these cases the bond enthalpy is just the energy required to break the molecule into its atoms. However, many important bonds, such as the C—H bond, exist only in polyatomic molecules. For these bonds, we usually use *average* bond enthalpies. For example, the enthalpy change for the following process in which a methane

molecule is decomposed into its five atoms (a process called *atomization*) can be used to define an average bond enthalpy for the C—H bond,

$$\begin{array}{ccc}
H \\
H - C - H(g) & \longrightarrow \dot{C} \cdot (g) + 4 H \cdot (g) & \Delta H = 1660 \text{ kJ} \\
H
\end{array}$$

Because there are four equivalent C—H bonds in methane, the enthalpy of atomization is equal to the sum of the bond enthalpies of the four C—H bonds. Therefore, the average C—H bond enthalpy for CH_4 is D(C-H) = (1660/4)kJ/mol = 415 kJ/mol.

The bond enthalpy for a given pair of atoms, say C—H, depends on the rest of the molecule containing the atom pair. However, the variation from one molecule to another is generally small, which supports the idea that bonding electron pairs are localized between atoms. If we consider C—H bond enthalpies in many different compounds, we find that the average bond enthalpy is 413 kJ/mol, close to the 415 kJ/mol we just calculated from CH_4 .

Give It Some Thought

How can you use the enthalpy of atomization of the hydrocarbon ethane, $C_2H_6(g)$, along with the value D(C-H) = 413 kJ/mol to estimate the value for D(C-C)?

▼ Table 8.4 lists average bond enthalpies for a number of atom pairs. *The bond enthalpy is always a positive quantity; energy is always required to break chemical bonds.* Conversely, *energy is always released when a bond forms between two gaseous atoms or*

molecular fragments. The greater the bond enthalpy, the stronger the bond. Further, a molecule with strong chemical bonds generally has less tendency to undergo chemical change than does one with weak bonds. For example, N_2 , which has a very strong $N \equiv N$ triple bond, is very unreactive, whereas hydrazine, N_2H_4 , which has an N - N single bond, is highly reactive.

Give It Some Thought

Based on bond enthalpies, which do you expect to be more reactive, oxygen, O_2 , or hydrogen peroxide, H_2O_2 ?

Bond Enthalpies and the Enthalpies of Reactions

We can use average bond enthalpies to estimate the enthalpies of reactions in which bonds are broken and new bonds are formed. This procedure allows us to estimate quickly whether a given reaction will be endothermic ($\Delta H > 0$) or exothermic ($\Delta H < 0$) even if we do not know $\Delta H_{\rm f}^{\circ}$ for all the species involved.

Our strategy for estimating reaction enthalpies is a straightforward application of Hess's law. ∞ (Section 5.6) We use the fact that breaking bonds is always endothermic and forming bonds is always exothermic. We therefore imagine that the reaction occurs in two steps:

- 1. We supply enough energy to break those bonds in the reactants that are not present in the products. The enthalpy of the system is increased by the sum of the bond enthalpies of the bonds that are broken.
- 2. We form the bonds in the products that were not present in the reactants. This step releases energy and therefore lowers the enthalpy of the system by the sum of the bond enthalpies of the bonds that are formed.

The enthalpy of the reaction, ΔH_{rxn} , is estimated as the sum of the bond enthalpies of the bonds broken minus the sum of the bond enthalpies of the bonds formed:

$$\Delta H_{\rm rxn} = \sum ({\rm bond\ enthalpies\ of\ bonds\ broken}) - \\ \sum ({\rm bond\ enthalpies\ of\ bonds\ formed}) \quad [8.12]$$

Consider, for example, the gas-phase reaction between methane, CH₄, and chlorine to produce methyl chloride, CH₃Cl, and hydrogen chloride, HCl:

$$H - CH_3(g) + Cl - Cl(g) \longrightarrow Cl - CH_3(g) + H - Cl(g)$$
 $\Delta H_{rxn} = ? [8.13]$

Our two-step procedure is outlined in **Figure 8.15**. We note that the following bonds are broken and made:

We first supply enough energy to break the C—H and Cl—Cl bonds, which raises the enthalpy of the system (indicated as $\Delta H_1 > 0$ in Figure 8.15). We then form the C—Cl and H—Cl bonds, which release energy and lower the enthalpy of the system ($\Delta H_2 < 0$). We then use Equation 8.12 and data from Table 8.4 to estimate the enthalpy of the reaction:

$$\Delta H_{\text{rxn}} = [D(C - H) + D(Cl - Cl)] - [D(C - Cl) + D(H - Cl)]$$

= (413 kJ + 242 kJ) - (328 kJ + 431 kJ) = -104 kJ

The reaction is exothermic because the bonds in the products (especially the H—Cl bond) are stronger than the bonds in the reactants (especially the Cl—Cl bond).

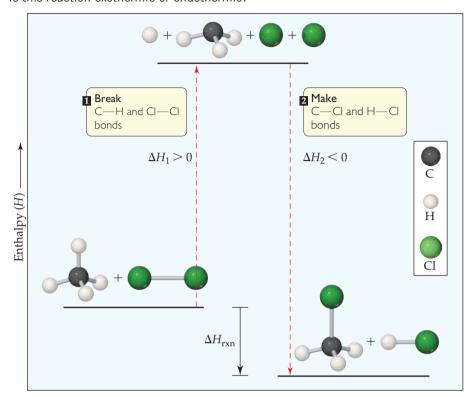

We usually use bond enthalpies to estimate $\Delta H_{\rm rxn}$ only if we do not have the needed ΔH_f° values readily available. For the preceding reaction, we cannot calculate $\Delta H_{\rm rxn}$ from ΔH_f° values and Hess's law because ΔH_f° for ${\rm CH_3Cl}(g)$ is not given in Appendix C. If we obtain the value of ΔH_f° for ${\rm CH_3Cl}(g)$ from another source and use Equation 5.31,

$$\Delta H_{\rm rxn}^{\circ} = \sum n \Delta H_f^{\circ}(\text{products}) - \sum m \Delta H_f^{\circ}(\text{reactants})$$

GO FIGURE

Is this reaction exothermic or endothermic?

▲ Figure 8.15 Using bond enthalpies to calculate ΔH_{rxn} . Average bond enthalpies are used to estimate ΔH_{rxn} for the reaction of methane with chlorine to make methyl chloride and hydrogen chloride.

we find that $\Delta H_{\rm rxn} = -99.8$ kJ for the reaction in Equation 8.13. Thus, the use of average bond enthalpies provides a reasonably accurate estimate of the actual reaction enthalpy change.

It is important to remember that bond enthalpies are derived for *gaseous* molecules and that they are often *averaged* values. Nonetheless, average bond enthalpies are useful for estimating reaction enthalpies quickly, especially for gas-phase reactions.

SAMPLE EXERCISE 8.12 Using Average Bond Enthalpies

Using data from Table 8.4, estimate ΔH for the combustion reaction

SOLUTION

Analyze We are asked to estimate the enthalpy change for a chemical reaction by using average bond enthalpies for the bonds broken and formed.

Plan In the reactants, we must break twelve C—H bonds and two C—C bonds in the two molecules of C_2H_6 and seven O=O bonds in the seven O_2 molecules. In the products, we form eight C=O bonds (two in each CO_2) and twelve O—H bonds (two in each H_2O).

Solve Using Equation 8.12 and data from Table 8.4, we have

$$\Delta H = [12D(C-H) + 2D(C-C) + 7D(O-O)] - [8D(C-O) + 12D(O-H)]$$

$$= [12(413 \text{ kJ}) + 2(348 \text{ kJ}) + 7(495 \text{ kJ})] - [8(799 \text{ kJ}) + 12(463 \text{ kJ})]$$

$$= 9117 \text{ kJ} - 11948 \text{ kJ}$$

$$= -2831 \text{ kJ}$$

Check This estimate can be compared with the value of -2856 kJ calculated from more accurate thermochemical data; the agreement is good.

Practice Exercise 1

Using Table 8.4, estimate ΔH for the "water splitting reaction": $H_2O(g) \rightarrow H_2(g) + \frac{1}{2}O_2(g)$. (a) 242 kJ, (b) 417 kJ, (c) 5 kJ, (d) -5 kJ, (e) -468 kJ

Practice Exercise 2

Using Table 8.4, estimate ΔH for the reaction

Bond Enthalpy and Bond Length

Just as we can define an average bond enthalpy, we can also define an average bond length for a number of common bonds (▼ Table 8.5). Of particular interest is the relationship, in any atom pair, among bond enthalpy, bond length, and number of bonds between the atoms. For example, we can use data in Tables 8.4 and 8.5 to compare the bond lengths and bond enthalpies of carbon–carbon single, double, and triple bonds:

C—C C=C C=C
$$1.54 \text{ Å}$$
 1.34 Å 1.20 Å 348 kJ/mol 614 kJ/mol 839 kJ/mol

Table 8.5 Average Bond Lengths for Some Single, Double, and Triple Bonds

Bond	Bond Length (Å)	Bond	Bond Length (Å)
С—С	1.54	N—N	1.47
C=C	1.34	N=N	1.24
C≡C	1.20	N≡N	1.10
C-N	1.43	N-O	1.36
C=N	1.38	N=O	1.22
C = N	1.16		
		0-0	1.48
C-O	1.43	0=0	1.21
c=0	1.23		
C≡O	1.13		

Chemistry Put to Work

Explosives and Alfred Nobel

Enormous amounts of energy can be stored in chemical bonds. Perhaps the most graphic illustration of this fact is seen in certain molecular substances used as explosives. Our discussion of bond enthalpies allows us to examine more closely some of the properties of such explosive substances.

A useful explosive substance must (1) decompose very exothermically, (2) have gaseous products so that a tremendous gas pressure accompanies the decomposition, (3) decompose very rapidly, and (4) be stable enough so that it can be detonated predictably. The combination of the first three effects leads to the violent evolution of heat and gases.

To give the most exothermic reaction, an explosive should have weak chemical bonds and should decompose into molecules that have very strong bonds. Table 8.4 tells us that $N \equiv N$, $C \equiv O$ and $C \equiv O$ bonds are among the strongest. Not surprisingly, explosives are usually designed to produce the gaseous products $N_2(g)$, CO(g), and $CO_2(g)$. Water vapor is nearly always produced as well.

Many common explosives are organic molecules that contain nitro (NO_2) or nitrate (NO_3) groups attached to a carbon skeleton. The Lewis structures of two of the most familiar explosives, nitroglycerin and trinitrotoluene (TNT), are shown here (resonance structures are not shown for clarity). TNT contains the six-membered ring characteristic of benzene.

Trinitrotoluene (TNT)

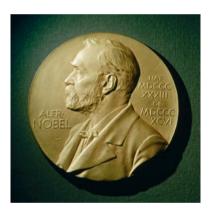

Nitroglycerin is a pale yellow, oily liquid. It is highly *shock-sensitive*: Merely shaking the liquid can cause its explosive decomposition into nitrogen, carbon dioxide, water, and oxygen gases:

$$4 C_3 H_5 N_3 O_9(l) \longrightarrow 6 N_2(g) + 12 CO_2(g) + 10 H_2 O(g) + O_2(g)$$

The large bond enthalpies of N_2 (941 kJ/mol), $CO_2(2 \times 799 \, kJ/mol)$, and $H_2O(2 \times 463 \, kJ/mol)$ make this reaction enormously exothermic. Nitroglycerin is an exceptionally unstable explosive because it is in nearly perfect *explosive balance*: With the exception of a small amount of $O_2(g)$ produced, the only products are N_2 , CO_2 , and H_2O . Note also that, unlike combustion reactions $O_2(g)$ 0 (Section 3.2), explosions are entirely self-contained. No other reagent, such as $O_2(g)$ 0, is needed for the explosive decomposition.

Because nitroglycerin is so unstable, it is difficult to use it as a controllable explosive. The Swedish inventor Alfred Nobel (V Figure 8.16) found that mixing nitroglycerin with an absorbent solid material such as diatomaceous earth or cellulose gives a solid explosive (dynamite) that is much safer than liquid nitroglycerin.

Related Exercises: 8.98, 8.99

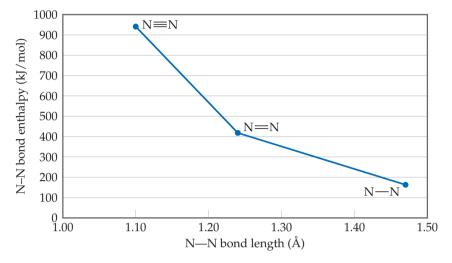

▲ Figure 8.16 Alfred Nobel (1833–1896), Swedish inventor of dynamite. By many accounts Nobel's discovery that nitroglycerin could be made more stable by absorbing it onto cellulose was an accident, but the discovery made Nobel a wealthy man. Although he had invented the most powerful military explosive to date, he strongly supported international peace movements. His will stated that his fortune be used to establish prizes awarding those who "have conferred the greatest benefit on mankind," including the promotion of peace and "fraternity between nations." The Nobel Prize is probably the most coveted award that a scientist, writer, or peace advocate can receive.

As the number of bonds between the carbon atoms increases, the bond length decreases and the bond enthalpy increases. That is, the carbon atoms are held more closely and more tightly together. In general, as the number of bonds between two atoms increases, the bond grows shorter and stronger. This trend is illustrated in \blacktriangleright Figure 8.17 for N—N single, double, and triple bonds.

GO FIGURE

Predict the N—N bond enthalpy for an N—N bond that has resonance forms that include equal contributions from single and double N-N bonds.

SAMPLE INTEGRATIVE EXERCISE

Putting Concepts Together

Phosgene, a substance used in poisonous gas warfare during World War I, is so named because it was first prepared by the action of sunlight on a mixture of carbon monoxide and chlorine gases. Its name comes from the Greek words phos (light) and genes (born of). Phosgene has the following elemental composition: 12.14% C, 16.17% O, and 71.69% Cl by mass. Its molar mass is 98.9 g/mol. (a) Determine the molecular formula of this compound. (b) Draw three Lewis structures for the molecule that satisfy the octet rule for each atom. (The Cl and O atoms bond to C.) (c) Using formal charges, determine which Lewis structure is the dominant one. (d) Using average bond enthalpies, estimate ΔH for the formation of gaseous phosgene from CO(g) and Cl₂(g).

SOLUTION

(a) The empirical formula of phosgene can be determined from its elemental composition. (Section 3.5) Assuming 100 g of the compound and calculating the number of moles of C, O, and Cl in this sample, we have

$$(12.14 \text{ g C}) \left(\frac{1 \text{ mol C}}{12.01 \text{ g C}}\right) = 1.011 \text{ mol C}$$
$$(16.17 \text{ g O}) \left(\frac{1 \text{ mol O}}{16.00 \text{ g O}}\right) = 1.011 \text{ mol O}$$
$$(71.69 \text{ g Cl}) \left(\frac{1 \text{ mol Cl}}{35.45 \text{ g Cl}}\right) = 2.022 \text{ mol Cl}$$

The ratio of the number of moles of each element, obtained by dividing each number of moles by the smallest quantity, indicates that there is one C and one O for each two Cl in the empirical formula, COCl₂.

The molar mass of the empirical formula is 12.01 + 16.00 + 2(35.45) = 98.91 g/mol, the same as the molar mass of the molecule. Thus, COCl₂ is the molecular formula.

(b) Carbon has four valence electrons, oxygen has six, and chlorine has seven, giving 4 + 6 + 2(7) = 24 electrons for the Lewis structures. Drawing a Lewis structure with all single bonds does not give the central carbon atom an octet. Using multiple bonds, three structures satisfy the octet rule:

$$: \ddot{\Box} - \ddot{C} - \ddot{\Box}: \longleftrightarrow \ddot{\Box} = \ddot{C} - \ddot{\Box}: \longleftrightarrow : \ddot{\Box} - \ddot{C} = \ddot{\Box}$$

(c) Calculating the formal charges on each atom gives

The first structure is expected to be the dominant one because it has the lowest formal charges on each atom. Indeed, the molecule is usually represented by this single Lewis structure.

(d) Writing the chemical equation in terms of the Lewis structures of the molecules, we have

$$:C \equiv O: \quad + \quad : \ddot{\square} - \ddot{\square}: \quad \longrightarrow \quad : \ddot{\square} - \overset{\circ}{\square} - \overset{\circ}{\square}: \\ : O: \quad \vdots \\$$

Thus, the reaction involves breaking a C≡O bond and a Cl — Cl bond and forming a C≡O bond and two C—Cl bonds. Using bond enthalpies from Table 8.4, we have

$$\Delta H = [D(C = O) + D(CI - CI)] - [D(C = O) + 2D(C - CI)]$$
$$= [1072 \text{ kJ} + 242 \text{ kJ}] - [799 \text{ kJ} + 2(328 \text{ kJ})] = -141 \text{ kJ}$$

Notice that the reaction is exothermic. Nevertheless, energy is needed from sunlight or another source for the reaction to begin, as is the case for the combustion of $H_2(g)$ and $O_2(g)$ to form $H_2O(g)$ (Figure 5.14).

Chapter Summary and Key Terms

CHEMICAL BONDS, LEWIS SYMBOLS, AND THE OCTET RULE (INTRODUCTION AND SECTION 8.1) In this chapter we have focused on the interactions that lead to the formation of chemical bonds. We classify these bonds into three broad groups: ionic bonds, which result from the electrostatic forces that exist between ions of opposite charge; covalent bonds, which result from the sharing of electrons by two atoms; and metallic bonds, which result from a delocalized sharing of electrons in metals. The formation of bonds involves interactions of the outermost electrons of atoms, their valence electrons. The valence electrons of an atom can be represented by electron-dot symbols, called Lewis symbols. The tendencies of atoms to gain, lose, or share their valence electrons often follow the octet rule, which says that the atoms in molecules or ions (usually) have eight valence electrons.

IONIC BONDING (SECTION 8.2) Ionic bonding results from the transfer of electrons from one atom to another, leading to the formation of a three-dimensional lattice of charged particles. The stabilities of ionic substances result from the strong electrostatic attractions between an ion and the surrounding ions of opposite charge. The magnitude of these interactions is measured by the lattice energy, which is the energy needed to separate an ionic lattice into gaseous ions. Lattice energy increases with increasing charge on the ions and with decreasing distance between the ions. The Born–Haber cycle is a useful thermochemical cycle in which we use Hess's law to calculate the lattice energy as the sum of several steps in the formation of an ionic compound.

COVALENT BONDING (SECTION 8.3) A covalent bond results from the sharing of valence electrons between atoms. We can represent the electron distribution in molecules by means of **Lewis structures**, which indicate how many valence electrons are involved in forming bonds and how many remain as **nonbonding electron pairs** (or **lone pairs**). The octet rule helps determine how many bonds will be formed between two atoms. The sharing of one pair of electrons produces a **single bond**; the sharing of two or three pairs of electrons

between two atoms produces **double** or **triple bonds**, respectively. Double and triple bonds are examples of multiple bonding between atoms. The bond length decreases as the number of bonds between the atoms increases.

BOND POLARITY AND ELECTRONEGATIVITY (SECTION 8.4) In

covalent bonds, the electrons may not necessarily be shared equally between two atoms. **Bond polarity** helps describe unequal sharing of electrons in a bond. In a **nonpolar covalent bond** the electrons in the bond are shared equally by the two atoms; in a **polar covalent bond** one of the atoms exerts a greater attraction for the electrons than the other.

Electronegativity is a numerical measure of the ability of an atom to compete with other atoms for the electrons shared between them. Fluorine is the most electronegative element, meaning it has the greatest ability to attract electrons from other atoms. Electronegativity values range from 0.7 for Cs to 4.0 for F. Electronegativity generally increases from left to right in a row of the periodic table and decreases going down a column. The difference in the electronegativities of bonded atoms can be used to determine the polarity of a bond. The greater the electronegativity difference, the more polar the bond.

A **polar molecule** is one whose centers of positive and negative charge do not coincide. Thus, a polar molecule has a positive side and a negative side. This separation of charge produces a **dipole**, the magnitude of which is given by the **dipole moment**, which is measured in debyes (D). Dipole moments increase with increasing amount of charge separated and increasing distance of separation. Any diatomic molecule X—Y in which X and Y have different electronegativities is a polar molecule.

Most bonding interactions lie between the extremes of covalent and ionic bonding. While it is generally true that the bonding between a metal and a nonmetal is predominantly ionic, exceptions to this guideline are not uncommon when the difference in electronegativity of the atoms is relatively small or when the oxidation state of the metal becomes large.

DRAWING LEWIS STRUCTURES AND RESONANCE STRUCTURES (SECTIONS 8.5 AND 8.6) If we know which atoms are connected to one another, we can draw Lewis structures for molecules and ions by a simple procedure. Once we do so, we can determine the **formal charge** of each atom in a Lewis structure, which is the charge that the atom would have if all atoms had the same electronegativity. In general, the dominant Lewis structure will have low formal charges with any negative formal charges residing on more electronegative atoms.

Sometimes a single dominant Lewis structure is inadequate to represent a particular molecule (or ion). In such situations, we describe the molecule by using two or more **resonance structures** for the molecule. The molecule is envisioned as a blend of these multiple resonance structures. Resonance structures are important in describing the bonding in molecules such as ozone, O_3 , and the organic molecule benzene, C_6H_6 .

EXCEPTIONS TO THE OCTET RULE (SECTION 8.7) The octet rule is not obeyed in all cases. Exceptions occur when (a) a molecule has an odd number of electrons, (b) it is not possible to complete an

octet around an atom without forcing an unfavorable distribution of electrons, or (c) a large atom is surrounded by a sufficiently large number of small electronegative atoms that it has more than an octet of electrons around it. Lewis structures with more than an octet of electrons are observed for atoms in the third row and beyond in the periodic table.

STRENGTHS AND LENGTHS OF COVALENT BONDS (SECTION 8.8)

The strength of a covalent bond is measured by its bond enthalpy, which is the molar enthalpy change upon breaking a particular bond. Average bond enthalpies can be determined for a wide variety of covalent bonds. The strengths of covalent bonds increase with the number of electron pairs shared between two atoms. We can use bond enthalpies to estimate the enthalpy change during chemical reactions in which bonds are broken and new bonds formed. The average bond length between two atoms decreases as the number of bonds between the atoms increases, consistent with the bond being stronger as the number of bonds increases.

Learning Outcomes After studying this chapter, you should be able to:

- Write Lewis symbols for atoms and ions. (Section 8.1)
- Define lattice energy and be able to arrange compounds in order of increasing lattice energy based on the charges and sizes of the ions involved. (Section 8.2)
- Use atomic electron configurations and the octet rule to draw Lewis structures for molecules. (Section 8.3)
- Use electronegativity differences to identify nonpolar covalent, polar covalent, and ionic bonds. (Section 8.4)
- Calculate charge separation in diatomic molecules based on the experimentally measured dipole moment and bond length. (Section 8.4)

- Calculate formal charges from Lewis structures and use those formal charges to identify the dominant Lewis structure for a molecule or ion. (Section 8.5)
- Recognize molecules where resonance structures are needed to describe the bonding and draw the dominant resonance structures. (Section 8.6)
- Recognize exceptions to the octet rule and draw accurate Lewis structures even when the octet rule is not obeyed. (Section 8.7)
- Predict the relationship between bond type (single, double, and triple), bond strength (or enthalpy), and bond length. (Section 8.8)
- Use bond enthalpies to estimate enthalpy changes for reactions involving gas-phase reactants and products. (Section 8.8)

Key Equations

•
$$E_{\rm el} = \frac{\kappa Q_1 Q_2}{d}$$
 [8.4]

The potential energy of two interacting charges

• $\mu = Qr$ [8.10]

The dipole moment of two charges of equal magnitude but opposite sign, separated by a distance r

• Formal charge = valence electrons - [8.11] $\frac{1}{2}$ (bonding electrons) - nonbonding electrons

The definition of formal charge

• $\Delta H_{\text{rxn}} = \sum (\text{bond enthalpies of bonds broken}) -$ [8.12] $\sum (\text{bond enthalpies of bonds formed})$

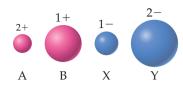

The enthalpy change as a function of bond enthalpies for reactions involving gas-phase molecules

Exercises

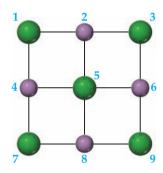

Visualizing Concepts

- **8.1** For each of these Lewis symbols, indicate the group in the periodic table in which the element X belongs: [Section 8.1]
 - (a) $\cdot \dot{X} \cdot$ (b) $\cdot X \cdot$ (c) $: \dot{X} \cdot$
- **8.2** Illustrated are four ions A, B, X, and Y— showing their relative ionic radii. The ions shown in red carry positive charges:

a 2+ charge for A and a 1+ charge for B. Ions shown in blue carry negative charges: a 1- charge for X and a 2- charge for Y. (a) Which combinations of these ions produce ionic compounds where there is a 1:1 ratio of cations and anions? (b) Among the combinations in part (a), which leads to the ionic compound having the largest lattice energy? [Section 8.2]

8.3 A portion of a two-dimensional "slab" of NaCl(s) is shown here (see Figure 8.3) in which the ions are numbered. (a) Which colored balls must represent sodium ions? (b) Which colored balls must represent chloride ions? (c) Consider ion 5. How many attractive electrostatic interactions are shown for it? (d) Consider ion 5. How many repulsive interactions are shown for it? (e) Is the sum of the attractive interactions in part (c) larger or smaller than the sum of the repulsive interactions in part (d)? (f) If this pattern of ions was extended indefinitely in two dimensions, would the lattice energy be positive or negative? [Section 8.2]

8.4 The orbital diagram that follows shows the valence electrons for a 2+ ion of an element. (a) What is the element?(b) What is the electron configuration of an atom of this element? [Section 8.2]

8.5 In the Lewis structure shown here, A, D, E, Q, X, and Z represent elements in the first two rows of the periodic table. Identify all six elements so that the formal charges of all atoms are zero. [Section 8.3]

8.6 Incomplete Lewis structures for the nitrous acid molecule, HNO₂, and the nitrite ion, NO₂⁻, are shown here. (a) Complete each Lewis structure by adding electron pairs as needed. (b) Is the formal charge on N the same or different in these two species? (c) Would either HNO₂ or NO₂⁻ be expected to exhibit resonance? (d) Would you expect the N=O bond in HNO₂ to be longer, shorter, or the same length as the N—O bonds in NO₂⁻? [Sections 8.5 and 8.6]

$$H-O-N=O O-N=O$$

8.7 The partial Lewis structure that follows is for a hydrocarbon molecule. In the full Lewis structure, each carbon atom satisfies the octet rule, and there are no unshared electron pairs in the molecule. The carbon-carbon bonds are labeled 1, 2, and 3. (a) How many hydrogen atoms are in the molecule?
(b) Rank the carbon-carbon bonds in order of increasing

bond length. (c) Rank the carbon–carbon bonds in order of increasing bond enthalpy. [Sections 8.3 and 8.8]

$$C \stackrel{1}{=} C \stackrel{2}{=} C \stackrel{3}{=} C$$

8.8 Consider the Lewis structure for the polyatomic oxyanion shown here, where X is an element from the third period (Na - Ar). By changing the overall charge, *n*, from 1- to 2- to 3- we get three different polyatomic ions. For each of these ions (a) identify the central atom, X; (b) determine the formal charge of the central atom, X; (c) draw a Lewis structure that makes the formal charge on the central atom equal to zero. [Sections 8.5, 8.6, and 8.7]

$$\begin{bmatrix} : \ddot{O}: \\ : \ddot{O}: -X - \ddot{O}: \\ \vdots \\ : \dot{O}: \end{bmatrix}^{n-1}$$

Lewis Symbols (Section 8.1)

- **8.9** (a) True or false: An element's number of valence electrons is the same as its atomic number. (b) How many valence electrons does a nitrogen atom possess? (c) An atom has the electron configuration $1s^22s^22p^63s^23p^2$. How many valence electrons does the atom have?
- **8.10** (a) True or false: The hydrogen atom is most stable when it has a full octet of electrons. (b) How many electrons must a sulfur atom gain to achieve an octet in its valence shell? (c) If an atom has the electron configuration $1s^22s^22p^3$, how many electrons must it gain to achieve an octet?
- **8.11** Consider the element silicon, Si. (a) Write its electron configuration. (b) How many valence electrons does a silicon atom have? (c) Which subshells hold the valence electrons?
- 8.12 (a) Write the electron configuration for the element titanium, Ti. How many valence electrons does this atom possess?(b) Hafnium, Hf, is also found in group 4B. Write the electron configuration for Hf. (c) Ti and Hf behave as though they possess the same number of valence electrons. Which of the subshells in the electron configuration of Hf behave as valence orbitals? Which behave as core orbitals?
- **8.13** Write the Lewis symbol for atoms of each of the following elements: (a) Al, (b) Br, (c) Ar, (d) Sr.
- **8.14** What is the Lewis symbol for each of the following atoms or ions? (a) K, (b) As, (c) Sn²⁺, (d) N³⁻.

Ionic Bonding (Section 8.2)

- 8.15 (a) Using Lewis symbols, diagram the reaction between magnesium and oxygen atoms to give the ionic substance MgO.(b) How many electrons are transferred? (c) Which atom loses electrons in the reaction?
- **8.16** (a) Use Lewis symbols to represent the reaction that occurs between Ca and F atoms. (b) What is the chemical formula of the most likely product? (c) How many electrons are transferred? (d) Which atom loses electrons in the reaction?
- **8.17** Predict the chemical formula of the ionic compound formed between the following pairs of elements: (a) Al and F, (b) K and S, (c) Y and O, (d) Mg and N.

- 8.18 Which ionic compound is expected to form from combining the following pairs of elements? (a) barium and fluorine, (b) cesium and chlorine, (c) lithium and nitrogen, (d) aluminum and oxygen.
- **8.19** Write the electron configuration for each of the following ions, and determine which ones possess noble-gas configurations: (a) Sr²⁺, (b) Ti²⁺, (c) Se²⁻, (d) Ni²⁺, (e) Br⁻, (f) Mn³⁺.
- **8.20** Write electron configurations for the following ions, and determine which have noble-gas configurations: (a) Cd^{2+} , (b) P^{3-} , (c) Zr^{4+} , (d) Ru^{3+} , (e) As^{3-} , (f) Ag^+ .
- **8.21** (a) Is lattice energy usually endothermic or exothermic? (b) Write the chemical equation that represents the process of lattice energy for the case of NaCl. (c) Would you expect salts like NaCl, which have singly-charged ions, to have larger or smaller lattice energies compared to salts like CaO which are composed of doubly-charged ions?
- **8.22** NaCl and KF have the same crystal structure. The only difference between the two is the distance that separates cations and anions. (a) The lattice energies of NaCl and KF are given in Table 8.2. Based on the lattice energies, would you expect the Na—Cl or the K—F distance to be longer? (b) Use the ionic radii given in Figure 7.8 to estimate the Na—Cl and K—F distances.
- 8.23 The ionic substances NaF, CaO, and ScN are isoelectronic (they have the same number of electrons). Examine the lattice energies for these substances in Table 8.2. Make a graph of lattice energy on the vertical axis versus the charge on the cation on the horizontal axis. (a) What is the slope of the line? (b) Make a graph of lattice energy on the vertical axis versus the square of the cation charge on the horizontal axis. What is the slope of this line? (c) Compare how well the data points fall on a line for the graphs in (a) and (b). Which trend is more linear, lattice energy versus cation charge or lattice energy versus cation charge squared? (d) Predict the lattice energy for the compound TiC, if we consider the carbon to have a 4— charge.
- 8.24 (a) Does the lattice energy of an ionic solid increase or decrease (i) as the charges of the ions increase, (ii) as the sizes of the ions increase? (b) Arrange the following substances not listed in Table 8.2 according to their expected lattice energies, listing them from lowest lattice energy to the highest: MgS, KI, GaN, LiBr.
- 8.25 Consider the ionic compounds KF, NaCl, NaBr, and LiCl. (a) Use ionic radii (Figure 7.8) to estimate the cation–anion distance for each compound. (b) Based on your answer to part (a), arrange these four compounds in order of decreasing lattice energy. (c) Check your predictions in part (b) with the experimental values of lattice energy from Table 8.2. Are the predictions from ionic radii correct?
- 8.26 Which of the following trends in lattice energy is due to differences in ionic radii? (a) NaCl > RbBr > CsBr,
 (b) BaO > KF, (c) SrO > SrCl₂.
- 8.27 Energy is required to remove two electrons from Ca to form Ca²⁺, and energy is required to add two electrons to O to form O²⁻. Yet CaO is stable relative to the free elements. Which statement is the best explanation? (a) The lattice energy of CaO is large enough to overcome these processes.
 (b) CaO is a covalent compound, and these processes are irrelevant. (c) CaO has a higher molar mass than either Ca or O.
 (d) The enthalpy of formation of CaO is small. (e) CaO is stable to atmospheric conditions.

- **8.28** List the individual steps used in constructing a Born–Haber cycle for the formation of BaI₂ from the elements. Which of the steps would you expect to be exothermic?
- **8.29** Use data from Appendix C, Figure 7.10, and Figure 7.12 to calculate the lattice energy of RbCl.
- **8.30** (a) Based on the lattice energies of MgCl₂ and SrCl₂ given in Table 8.2, what is the range of values that you would expect for the lattice energy of CaCl₂? (b) Using data from Appendix C, Figure 7.11, Figure 7.13 and the value of the second ionization energy for Ca, 1145 kJ/mol, calculate the lattice energy of CaCl₂.

Covalent Bonding, Electronegativity, and Bond Polarity (Sections 8.3 and 8.4)

- **8.31** (a) State whether the bonding in each compound is likely to be covalent or not: (i) iron, (ii) sodium chloride, (iii) water, (iv) oxygen, (v) argon. (b) A substance XY, formed from two different elements, boils at -33 °C. Is XY likely to be a covalent or an ionic substance?
- **8.32** Which of these elements are unlikely to form covalent bonds? S, H, K, Ar, Si.
- 8.33 Using Lewis symbols and Lewis structures, diagram the formation of SiCl₄ from Si and Cl atoms, showing valence-shell electrons. (a) How many valence electrons does Si have initially? (b) How many valence electrons does each Cl have initially? (c) How many valence electrons surround the Si in the SiCl₄ molecule? (d) How many valence electrons surround each Cl in the SiCl₄ molecule? (e) How many bonding pairs of electrons are in the SiCl₄ molecule?
- 8.34 Use Lewis symbols and Lewis structures to diagram the formation of PF₃ from P and F atoms, showing valence-shell electrons. (a) How many valence electrons does P have initially? (b) How many valence electrons does each F have initially? (c) How many valence electrons surround the P in the PF₃ molecule? (d) How many valence electrons surround each F in the PF₃ molecule? (e) How many bonding pairs of electrons are in the PF₃ molecule?
- **8.35** (a) Construct a Lewis structure for O₂ in which each atom achieves an octet of electrons. (b) How many bonding electrons are in the structure? (c) Would you expect the O—O bond in O₂ to be shorter or longer than the O—O bond in compounds that contain an O—O single bond? Explain.
- 8.36 (a) Construct a Lewis structure for hydrogen peroxide, H₂O₂, in which each atom achieves an octet of electrons. (b) How many bonding electrons are between the two oxygen atoms?
 (c) Do you expect the O—O bond in H₂O₂ to be longer or shorter than the O—O bond in O₂? Explain.
- 8.37 Which of the following statements about electronegativity is false? (a) Electronegativity is the ability of an atom in a molecule to attract electron density toward itself. (b) Electronegativity is the same thing as electron affinity. (c) The numerical values for electronegativity have no units. (d) Fluorine is the most electronegative element. (e) Cesium is the least electronegative element.
- 8.38 (a) What is the trend in electronegativity going from left to right in a row of the periodic table? (b) How do electronegativity values generally vary going down a column in the periodic table? (c) True or false: The most easily ionizable elements are the most electronegative.

- **8.39** Using only the periodic table as your guide, select the most electronegative atom in each of the following sets: (a) Na, Mg, K, Ca; (b) P, S, As, Se; (c) Be, B, C, Si; (d) Zn, Ge, Ga, As.
- **8.40** By referring only to the periodic table, select (a) the most electronegative element in group 6A; (b) the least electronegative element in the group Al, Si, P; (c) the most electronegative element in the group Ga, P, Cl, Na; (d) the element in the group K, C, Zn, F that is most likely to form an ionic compound with Ba.
- **8.41** Which of the following bonds are polar? (a) B—F, (b) Cl—Cl, (c) Se—O, (d) H—I. Which is the more electronegative atom in each polar bond?
- 8.42 Arrange the bonds in each of the following sets in order of increasing polarity: (a) C—F, O—F, Be—F; (b) O—Cl, S—Br, C—P; (c) C—S, B—F, N—O.
- **8.43** (a) From the data in Table 8.3, calculate the effective charges on the H and Br atoms of the HBr molecule in units of the electronic charge, *e*. (b) If you were to put HBr under very high pressure, so its bond length decreased significantly, would its dipole moment increase, decrease, or stay the same, if you assume that the effective charges on the atoms do not change?
- **8.44** The iodine monobromide molecule, IBr, has a bond length of 2.49 Å and a dipole moment of 1.21 D. (a) Which atom of the molecule is expected to have a negative charge? (b) Calculate the effective charges on the I and Br atoms in IBr in units of the electronic charge, *e*.
- 8.45 In the following pairs of binary compounds determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound:

 (a) SiF₄ and LaF₃,
 (b) FeCl₂ and ReCl₆,
 (c) PbCl₄ and RbCl.
- **8.46** In the following pairs of binary compounds determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (a) TiCl₄ and CaF₂, (b) ClF₃ and VF₃, (c) SbCl₅ and AlF₃.

Lewis Structures; Resonance Structures (Sections 8.5 and 8.6)

- **8.47** Draw Lewis structures for the following: (a) SiH₄, (b) CO, (c) SF₂, (d) H₂SO₄ (H is bonded to O), (e) ClO₂⁻, (f) NH₂OH.
- **8.48** Write Lewis structures for the following: (a) H₂CO (both H atoms are bonded to C), (b) H₂O₂, (c) C₂F₆ (contains a C—C bond), (d) AsO₃³⁻, (e) H₂SO₃ (H is bonded to O), (f) NH₂Cl.
- 8.49 Which one of these statements about formal charge is true?

 (a) Formal charge is the same as oxidation number. (b) To draw the best Lewis structure, you should minimize formal charge. (c) Formal charge takes into account the different electronegativities of the atoms in a molecule. (d) Formal charge is most useful for ionic compounds. (e) Formal charge is used in calculating the dipole moment of a diatomic molecule.
- **8.50** (a) Draw the dominant Lewis structure for the phosphorus trifluoride molecule, PF₃. (b) Determine the oxidation numbers of the P and F atoms. (c) Determine the formal charges of the P and F atoms.
- **8.51** Write Lewis structures that obey the octet rule for each of the following, and assign oxidation numbers and formal charges to each atom: (a) OCS, (b) SOCl₂ (S is the central atom), (c) BrO₃⁻, (d) HClO₂ (H is bonded to O).

- 8.52 For each of the following molecules or ions of sulfur and oxygen, write a single Lewis structure that obeys the octet rule, and calculate the oxidation numbers and formal charges on all the atoms: (a) SO₂, (b) SO₃, (c) SO₃²⁻. (d) Arrange these molecules/ions in order of increasing S—O bond length.
- 8.53 (a) Draw the best Lewis structure(s) for the nitrite ion, NO₂⁻. (b) With what allotrope of oxygen is it isoelectronic? (c) What would you predict for the lengths of the bonds in NO₂⁻ relative to N—O single bonds and double bonds?
- **8.54** Consider the formate ion, HCO₂⁻, which is the anion formed when formic acid loses an H⁺ ion. The H and the two O atoms are bonded to the central C atom. (a) Draw the best Lewis structure(s) for this ion. (b) Are resonance structures needed to describe the structure? (c) Would you predict that the C—O bond lengths in the formate ion would be longer or shorter relative to those in CO₂?
- **8.55** Predict the ordering, from shortest to longest, of the bond lengths in CO, CO₂, and CO₃²⁻.
- **8.56** Based on Lewis structures, predict the ordering, from shortest to longest, of N—O bond lengths in NO⁺, NO₂⁻, and NO₃⁻.
- 8.57 (a) Do the C—C bond lengths in benzene alternate shortlong-short-long around the ring? Why or why not? (b) Are C—C bond lengths in benzene shorter than C—C single bonds? (c) Are C—C bond lengths in benzene shorter than C=C double bonds?
- [8.58] Mothballs are composed of naphthalene, C₁₀H₈, a molecule that consists of two six-membered rings of carbon fused along an edge, as shown in this incomplete Lewis structure:

(a) Draw all of the resonance structures of naphthalene. How many are there? (b) Do you expect the C—C bond lengths in the molecule to be similar to those of C—C single bonds, C=C double bonds, or intermediate between C—C single and C=C double bonds? (c) Not all of the C—C bond lengths in naphthalene are equivalent. Based on your resonance structures, how many C—C bonds in the molecule do you expect to be shorter than the others?

Exceptions to the Octet Rule (Section 8.7)

8.59 Indicate whether each statement is true or false: (a) The octet rule is based on the fact that filling in all *s* and *p* valence electrons in a shell gives eight electrons. (b) The Si in SiH₄ does not follow the octet rule because hydrogen is in an unusual oxidation state. (c) Boron compounds are frequent exceptions to the octet rule because they have too few electrons surrounding the boron. (d) Compounds in which nitrogen is the central atom are frequent exceptions to the octet rule because they have too many electrons surrounding the nitrogen.

337

- **8.60** Fill in the blank with the appropriate numbers for both electrons and bonds (considering that single bonds are counted as one, double bonds as two, and triple bonds as three).
 - (a) Fluorine has _____ valence electrons and makes ____ bond(s) in compounds.
 - **(b)** Oxygen has ____ valence electrons and makes ____ bond(s) in compounds.
 - (c) Nitrogen has _____ valence electrons and makes ____ bond(s) in compounds.
 - (d) Carbon has _____ valence electrons and makes_____ bond(s) in compounds.
- 8.61 Draw the dominant Lewis structures for these chlorine-oxygen molecules/ions: ClO, ClO⁻, ClO₂⁻, ClO₃⁻, ClO₄⁻. Which of these do not obey the octet rule?
- 8.62 For elements in the third row of the periodic table and bevond, the octet rule is often not obeyed. A friend of yours says this is because these heavier elements are more likely to make double or triple bonds. Another friend of yours says that this is because the heavier elements are larger and can make bonds to more than four atoms at a time. Which friend is most correct?
- **8.63** Draw the Lewis structures for each of the following ions or molecules. Identify those in which the octet rule is not obeyed: state which atom in each compound does not follow the octet rule; and state, for those atoms, how many electrons surround these atoms: (a) PH_3 , (b) AlH_3 , (c) N_3^- , (d) CH_2Cl_2 , (e) SnF_6 .
- **8.64** Draw the Lewis structures for each of the following molecules or ions. Identify instances where the octet rule is not obeyed; state which atom in each compound does not follow the octet rule; and state how many electrons surround these atoms: (a) NO, (b) BF₃, (c) ICl₂⁻, (d) OPBr₃ (the P is the central atom), (e) XeF_4 .
- 8.65 In the vapor phase, BeCl₂ exists as a discrete molecule. (a) Draw the Lewis structure of this molecule, using only single bonds. Does this Lewis structure satisfy the octet rule? (b) What other resonance structures are possible that satisfy the octet rule? (c) On the basis of the formal charges, which Lewis structure is expected to be dominant for BeCl₂?
- 8.66 (a) Describe the molecule xenon trioxide, XeO₃, using four possible Lewis structures, one each with zero, one, two, or three Xe—O double bonds. (b) Do any of these resonance structures satisfy the octet rule for every atom in the molecule? (c) Do any of the four Lewis structures have multiple resonance structures? If so, how many resonance structures do you find? (d) Which of the Lewis structures in (a) yields the most favorable formal charges for the molecule?
- **8.67** Consider the following statement: "For some molecules and ions, a Lewis structure that satisfies the octet rule does not lead to the lowest formal charges, and a Lewis structure that leads to the lowest formal charges does not satisfy the octet rule." Illustrate this statement using the hydrogen sulfite ion, HSO₃⁻, as an example (the H atom is bonded to one of the O atoms).
- 8.68 Some chemists believe that satisfaction of the octet rule should be the top criterion for choosing the dominant Lewis structure of a molecule or ion. Other chemists believe that achieving the best formal charges should be the top criterion. Consider the dihydrogen phosphate ion, H₂PO₄⁻, in which the H atoms are bonded to O atoms. (a) What is the predicted dominant Lewis structure if satisfying the octet rule is the top

criterion? (b) What is the predicted dominant Lewis structure if achieving the best formal charges is the top criterion?

Bond Enthalpies (Section 8.8)

8.69 Using Table 8.4, estimate ΔH for each of the following gasphase reactions (note that lone pairs on atoms are not shown):

(c)
$$2 \text{ Cl} - \text{N} - \text{Cl} \longrightarrow \text{N} = \text{N} + 3 \text{ Cl} - \text{Cl}$$

8.70 Using Table 8.4, estimate ΔH for the following gas-phase

(a)
$$Br - C - H + Cl - Cl \longrightarrow Br - C - Cl + H - Cl$$

$$Br Br Br Br$$

- **8.71** Using Table 8.4, estimate ΔH for each of the following reactions:
 - (a) $2 \text{ CH}_4(g) + \text{O}_2(g) \longrightarrow 2 \text{ CH}_3 \text{OH}(g)$
 - **(b)** $H_2(g) + Br_2(l) \longrightarrow 2 HBr(g)$
 - (c) $2 H_2 O_2(g) \longrightarrow 2 H_2 O(g) + O_2(g)$
- 8.72 Use Table 8.4 to estimate the enthalpy change for each of the following reactions:
 - (a) $H_2C = O(g) + HCl(g) \longrightarrow H_3C O Cl(g)$
 - **(b)** $H_2O_2(g) + 2 CO(g) \longrightarrow H_2(g) + 2 CO_2(g)$
 - (c) $3 H_2C = CH_2(g) \longrightarrow C_6H_{12}(g)$ (the six carbon atoms form a six-membered ring with two H atoms on each C atom)

8.73 Ammonia is produced directly from nitrogen and hydrogen by using the Haber process, which is perhaps the most widely used industrial chemical reaction on Earth. The chemical reaction is

$$N_2(g) + 3 H_2(g) \longrightarrow 2 NH_3(g)$$

- (a) Use Table 8.4 to estimate the enthalpy change for the reaction. Is it exothermic or endothermic?
- **(b)** Calculate the enthalpy change as obtained using ΔH_f° values.
- **8.74** (a) Use bond enthalpies to estimate the enthalpy change for the reaction of hydrogen with ethylene:

$$H_2(g) + C_2H_4(g) \longrightarrow C_2H_6(g)$$

- **(b)** Calculate the standard enthalpy change for this reaction, using heat of formation.
- **8.75** Given the following bond-dissociation energies, calculate the average bond enthalpy for the Ti—Cl bond.

Δ	H(kJ/mol)
$TiCl_4(g) \longrightarrow TiCl_3(g) + Cl(g)$	335
$TiCl_3(g) \longrightarrow TiCl_2(g) + Cl(g)$	423
$TiCl_2(g) \longrightarrow TiCl(g) + Cl(g)$	444
$TiCl(g) \longrightarrow Ti(g) + Cl(g)$	519

8.76 (a) Using average bond enthalpies, predict which of the following reactions will be most exothermic:

(i)
$$C(g) + 2 F_2(g) \longrightarrow CF_4(g)$$

(ii)
$$CO(g) + 3 F_2(g) \longrightarrow CF_4(g) + OF_2(g)$$

(iii)
$$CO_2(g) + 4 F_2(g) \longrightarrow CF_4(g) + 2 OF_2(g)$$

- (b) Make a graph that plots the reaction enthalpy you calculated on the vertical axis versus oxidation state of carbon on the horizontal axis. Draw the best-fit line through your data points. Is the slope of this line negative or positive? Does this mean that as the oxidation state of the carbon increases, the reaction with elemental fluorine becomes more or less exothermic?
- (c) Predict the reaction enthalpy for the reaction of carbonate ion with fluorine from your graph, and compare to what you predict using average bond enthalpies.

Additional Exercises

- **8.77** How many elements in the periodic table are represented by a Lewis symbol with a single dot? Which groups are they in?
- [8.78] From Equation 8.4 and the ionic radii given in Figure 7.8, calculate the potential energy of the following pairs of ions. Assume that the ions are separated by a distance equal to the sum of their ionic radii: (a) Na⁺, Br⁻; (b) Rb⁺, Br⁻; (c) Sr²⁺, S²⁻.
- 8.79 (a) Consider the lattice energies for the following compounds: BeH₂, 3205 kJ/mol; MgH₂, 2791 kJ/mol; CaH₂, 2410 kJ/mol; SrH₂, 2250 kJ/mol; BaH₂, 2121 kJ/mol. Plot lattice energy versus cation radius for these compounds. If you draw a line through your points, is the slope negative or positive? Explain.
 (b) The lattice energy of ZnH₂ is 2870 kJ/mol. Based on the data given in part (a), the radius of the Zn²⁺ ion is expected to be closest to that of which group 2A element?
- **8.80** Based on data in Table 8.2, estimate (within 30 kJ/mol) the lattice energy for (a) LiBr, (b) CsBr, (c) CaCl₂.
- **8.81** An ionic substance of formula MX has a lattice energy of 6×10^3 kJ/mol. Is the charge on the ion M likely to be 1+, 2+, or 3+? Explain.
- [8.82] From the ionic radii given in Figure 7.8, calculate the potential energy of a Ca²⁺ and O²⁻ ion pair that is just touching (the magnitude of the electronic charge is given on the back-inside cover). Calculate the energy of a mole of such pairs. How does this value compare with the lattice energy of CaO (Table 8.2)? Explain.
- **8.83** Construct a Born–Haber cycle for the formation of the hypothetical compound NaCl₂, where the sodium ion has a 2+ charge (the second ionization energy for sodium is given in Table 7.2). (a) How large would the lattice energy need to be

- for the formation of NaCl₂ to be exothermic? (b) If we were to estimate the lattice energy of NaCl₂ to be roughly equal to that of MgCl₂ (2326 kJ/mol from Table 8.2), what value would you obtain for the standard enthalpy of formation, ΔH_f° , of NaCl₂?
- **8.84** A classmate of yours is convinced that he knows everything about electronegativity. (a) In the case of atoms X and Y having different electronegativities, he says, the diatomic molecule X—Y must be polar. Is your classmate correct? (b) Your classmate says that the farther the two atoms are apart in a bond, the larger the dipole moment will be. Is your classmate correct?
- 8.85 Consider the collection of nonmetallic elements O, P, Te, I and B. (a) Which two would form the most polar single bond? (b) Which two would form the longest single bond? (c) Which two would be likely to form a compound of formula XY₂? (d) Which combinations of elements would likely yield a compound of empirical formula X₂Y₃?
- 8.86 The substance chlorine monoxide, ClO(*g*), is important in atmospheric processes that lead to depletion of the ozone layer. The ClO molecule has an experimental dipole moment of 1.24 D, and the Cl—O bond length is 1.60 Å. (a) Determine the magnitude of the charges on the Cl and O atoms in units of the electronic charge, *e*. (b) Based on the electronegativities of the elements, which atom would you expect to have a partial negative charge in the ClO molecule? (c) Using formal charges as a guide, propose the dominant Lewis structure for the molecule. (d) The anion ClO⁻ exists. What is the formal charge on the Cl for the best Lewis structure for ClO⁻?
- [8.87] (a) Using the electronegativities of Br and Cl, estimate the partial charges on the atoms in the Br—Cl molecule.

339

- 8.88 A major challenge in implementing the "hydrogen economy" is finding a safe, lightweight, and compact way of storing hydrogen for use as a fuel. The hydrides of light metals are attractive for hydrogen storage because they can store a high weight percentage of hydrogen in a small volume. For example, NaAlH₄ can release 5.6% of its mass as H₂ upon decomposing to NaH(s), Al(s), and H₂(g). NaAlH₄ possesses both covalent bonds, which hold polyatomic anions together, and ionic bonds. (a) Write a balanced equation for the decomposition of NaAlH₄. (b) Which element in NaAlH₄ is the most electronegative? Which one is the least electronegative? (c) Based on electronegativity differences, predict the identity of the polyatomic anion. Draw a Lewis structure for this ion. (d) What is the formal charge on hydrogen in the polyatomic ion?
- 8.89 Although I₃ is known, F₃ is not. Which statement is the most correct explanation? (a) Iodine is more likely to be electron-deficient. (b) Fluorine is too small to accommodate three nonbonding electron pairs and two bonding electron pairs. (c) Fluorine is too electronegative to form anions. (d) I₂ is known but F₂ is not. (e) Iodine has a larger electron affinity than fluorine.
- **8.90** Calculate the formal charge on the indicated atom in each of the following molecules or ions: (a) the central oxygen atom in O₃, (b) phosphorus in PF₆⁻, (c) nitrogen in NO₂, (d) iodine in ICl₃, (e) chlorine in HClO₄ (hydrogen is bonded to O).
- 8.91 (a) Determine the formal charge on the chlorine atom in the hypochlorite ion, ClO⁻, and the perchlorate ion, ClO₄⁻, using resonance structures where the Cl atom has an octet.
 (b) What are the oxidation numbers of chlorine in ClO⁻ and in ClO₄⁻? (c) Perchlorate is a much stronger oxidizing agent than hypochlorite. Suggest an explanation.
- **8.92** The following three Lewis structures can be drawn for $N_2O: N \equiv N \ddot{O}: \longleftrightarrow : \ddot{N} N \equiv O: \longleftrightarrow : \ddot{N} = N = \ddot{O}:$
 - (a) Using formal charges, which of these three resonance forms is likely to be the most important? (b) The N—N bond length in N_2O is 1.12 Å, slightly longer than a typical N \equiv N bond; and the N—O bond length is 1.19 Å, slightly shorter than a typical bond (see Table 8.5). Based on these data, which resonance structure best represents N_2O ?
- [8.93] (a) Triazine, C₃H₃N₃, is like benzene except that in triazine every other C—H group is replaced by a nitrogen atom. Draw the Lewis structure(s) for the triazine molecule. (b) Estimate the carbon–nitrogen bond distances in the ring.
- [8.94] Ortho-dichlorobenzene, $C_6H_4Cl_2$, is obtained when two of the adjacent hydrogen atoms in benzene are replaced with Cl atoms. A skeleton of the molecule is shown here. (a) Complete a Lewis structure for the molecule using bonds and electron pairs as needed. (b) Are there any resonance structures for the molecule? If so, sketch them. (c) Are the resonance structures in (a) and (b) equivalent to one another as they are in benzene?

$$H$$
 $C-C$
 $H-C$
 $C-C$
 $C-C$
 $C-C$

- **8.95** Consider the hypothetical molecule B—A=B. Are the following statements true or false? (a) This molecule cannot exist. (b) If resonance was important, the molecule would have identical A-B bond lengths.
- **8.96** An important reaction for the conversion of natural gas to other useful hydrocarbons is the conversion of methane to ethane.

$$2 CH_4(g) \longrightarrow C_2H_6(g) + H_2(g)$$

In practice, this reaction is carried out in the presence of oxygen, which converts the hydrogen produced into water.

$$2 CH_4(g) + \frac{1}{2}O_2(g) \longrightarrow C_2H_6(g) + H_2O(g)$$

Use Table 8.4 to estimate ΔH for these two reactions. Why is the conversion of methane to ethane more favorable when oxygen is used?

8.97 Two compounds are isomers if they have the same chemical formula but different arrangements of atoms. Use Table 8.4 to estimate ΔH for each of the following gas-phase isomerization reactions and indicate which isomer has the lower enthalpy.

(a)
$$H - C - C - O - H \longrightarrow H - C - O - C - H$$

 $H + H + H + H$

Ethanol

Dimethyl ether

(b)
$$H-C-C-H \rightarrow H-C-C-H$$

Ethylene oxide

Acetaldehyde

Cyclopentene

Pentadiene

Methyl isocyanide

Acetonitrile

[8.98] With reference to the Chemistry Put to Work box on explosives, (a) use bond enthalpies to estimate the enthalpy change for the explosion of 1.00 g of nitroglycerin. (b) Write a balanced equation for the decomposition of TNT. Assume that, upon explosion, TNT decomposes into N₂(g), CO₂(g), H₂O(g), and C(s). **8.99** The "plastic" explosive C-4, often used in action movies, contains the molecule *cyclotrimethylenetrinitramine*, which is often called RDX (for Royal Demolition eXplosive):

Cyclotrimethylenetrinitramine (RDX)

(a) Complete the Lewis structure for the molecule by adding unshared electron pairs where they are needed. (b) Does the Lewis structure you drew in part (a) have any resonance

- structures? If so, how many? (c) The molecule causes an explosion by decomposing into CO(g), $N_2(g)$, and $H_2O(g)$. Write a balanced equation for the decomposition reaction. (d) With reference to Table 8.4, which is the weakest type of bond in the molecule? (e) Use average bond enthalpies to estimate the enthalpy change when 5.0 g of RDX decomposes.
- 8.100 The bond lengths of carbon-carbon, carbon-nitrogen, carbon-oxygen, and nitrogen-nitrogen single, double, and triple bonds are listed in Table 8.5. Plot bond enthalpy (Table 8.4) versus bond length for these bonds (as in Figure 8.17). (a) Is this statement true: "The longer the bond, the stronger the bond"? (b) Order the relative strengths of C—C, C—N, C—O, and N—N bonds from weakest to strongest. (c) From your graph for the carbon-carbon bond in part (a), estimate the bond enthalpy of the hypothetical C≡C quadruple bond.

Integrative Exercises

- **8.101** The Ti²⁺ ion is isoelectronic with the Ca atom. (a) Write the electron configurations of Ti²⁺ and Ca. (b) Calculate the number of unpaired electrons for Ca and for Ti²⁺. (c) What charge would Ti have to be isoelectronic with Ca²⁺?
- **8.102** (a) Write the chemical equations that are used in calculating the lattice energy of $SrCl_2(s)$ via a Born–Haber cycle. (b) The second ionization energy of Sr(g) is 1064 kJ/mol. Use this fact along with data in Appendix C, Figure 7.10, Figure 7.12, and Table 8.2 to calculate ΔH_f° for $SrCl_2(s)$.
- 8.103 The electron affinity of oxygen is $-141 \, kJ/mol$, corresponding to the reaction

$$O_2(g) + e^- \longrightarrow O^-(g)$$

The lattice energy of $K_2O(s)$ is 2238 kJ/mol. Use these data along with data in Appendix C and Figure 7.10 to calculate the "second electron affinity" of oxygen, corresponding to the reaction

$$O^{-}(g) + e^{-} \longrightarrow O^{2-}(g)$$

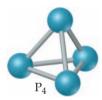

- 8.104 You and a partner are asked to complete a lab entitled "Oxides of Ruthenium" that is scheduled to extend over two lab periods. The first lab, which is to be completed by your partner, is devoted to carrying out compositional analysis. In the second lab, you are to determine melting points. Upon going to lab you find two unlabeled vials, one containing a soft yellow substance and the other a black powder. You also find the following notes in your partner's notebook—*Compound 1*: 76.0% Ru and 24.0% O (by mass), *Compound 2*: 61.2% Ru and 38.8% O (by mass).
 - (a) What is the empirical formula for Compound 1?
 - **(b)** What is the empirical formula for Compound 2?

Upon determining the melting points of these two compounds, you find that the yellow compound melts at 25 $^{\circ}$ C, while the black powder does not melt up to the maximum temperature of your apparatus, 1200 $^{\circ}$ C.

- (c) What is the identity of the yellow compound?
- (d) What is the identity of the black compound?
- (e) Which compound is molecular?
- (f) Which compound is ionic?

- 8.105 One scale for electronegativity is based on the concept that the electronegativity of any atom is proportional to the ionization energy of the atom minus its electron affinity: electronegativity = k(I - EA), where k is a proportionality constant. (a) How does this definition explain why the electronegativity of F is greater than that of Cl even though Cl has the greater electron affinity? (b) Why are both ionization energy and electron affinity relevant to the notion of electronegativity? (c) By using data in Chapter 7, determine the value of k that would lead to an electronegativity of 4.0 for F under this definition. (d) Use your result from part (c) to determine the electronegativities of Cl and O using this scale. (e) Another scale for electronegativity defines electronegativity as the average of an atom's first ionization energy and its electron affinity. Using this scale, calculate the electronegativities for the halogens, and scale them so fluorine has an electronegativity of 4.0. On this scale, what is Br's electronegativity?
- 8.106 The compound chloral hydrate, known in detective stories as knockout drops, is composed of 14.52% C, 1.83% H, 64.30% Cl, and 13.35% O by mass, and has a molar mass of 165.4 g/mol. (a) What is the empirical formula of this substance? (b) What is the molecular formula of this substance? (c) Draw the Lewis structure of the molecule, assuming that the Cl atoms bond to a single C atom and that there are a C—C bond and two C—O bonds in the compound.
- **8.107** Barium azide is 62.04% Ba and 37.96% N. Each azide ion has a net charge of 1—. (a) Determine the chemical formula of the azide ion. (b) Write three resonance structures for the azide ion. (c) Which structure is most important? (d) Predict the bond lengths in the ion.
- 8.108 Acetylene (C₂H₂) and nitrogen (N₂) both contain a triple bond, but they differ greatly in their chemical properties.
 (a) Write the Lewis structures for the two substances. (b) By referring to Appendix C, look up the enthalpies of formation of acetylene and nitrogen. Which compound is more stable?
 (c) Write balanced chemical equations for the complete oxidation of N₂ to form N₂O₅(g) and of acetylene to form CO₂(g) and H₂O(g). (d) Calculate the enthalpy of oxidation per mole for N₂ and for C₂H₂ (the enthalpy of formation of N₂O₅(g) is 11.30 kJ/mol). (e) Both N₂ and C₂H₂ possess triple bonds with quite high bond enthalpies (Table 8.4). Calculate

- the enthalpy of hydrogenation per mole for both compounds: acetylene plus H_2 to make methane, CH_4 ; nitrogen plus H_2 to make ammonia, NH_3 .
- 8.109 Under special conditions, sulfur reacts with anhydrous liquid ammonia to form a binary compound of sulfur and nitrogen. The compound is found to consist of 69.6% S and 30.4% N. Measurements of its molecular mass yield a value of 184.3 g/mol. The compound occasionally detonates on being struck or when heated rapidly. The sulfur and nitrogen atoms of the molecule are joined in a ring. All the bonds in the ring are of the same length. (a) Calculate the empirical and molecular formulas for the substance. (b) Write Lewis structures for the molecule, based on the information you are given. (Hint: You should find a relatively small number of dominant Lewis structures.) (c) Predict the bond distances between the atoms in the ring. (*Note*: The S — S distance in the S_8 ring is 2.05 Å.) (d) The enthalpy of formation of the compound is estimated to be 480 kJ/mol^{-1} . ΔH_f° of S(g) is $222.8 \text{ kJ/mol}^{-1}$. Estimate the average bond enthalpy in the compound.
- 8.110 A common form of elemental phosphorus is the tetrahedral P_4 molecule, where all four phosphorus atoms are equivalent:

At room temperature phosphorus is a solid. (a) Are there any lone pairs of electrons in the P_4 molecule? (b) How many P - P bonds are there in the molecule? (c) Draw a Lewis structure for a linear P_4 molecule that satisfies the octet rule. Does this molecule have resonance structures? (d) On the basis of formal charges, which is more stable, the linear molecule or the tetrahedral molecule?

- 8.111 Consider benzene (C₆H₆) in the gas phase. (a) Write the reaction for breaking all the bonds in C₆H₆(g), and use data in Appendix C to determine the enthalpy change for this reaction. (b) Write a reaction that corresponds to breaking all the carbon-carbon bonds in C₆H₆(g). (c) By combining your answers to parts (a) and (b) and using the average bond enthalpy for C—H from Table 8.4, calculate the average bond enthalpy for the carbon-carbon bonds in C₆H₆(g). (d) Compare your answer from part (c) to the values for C—C single bonds and C=C double bonds in Table 8.4. Is benzene's C—C bond enthalpy exactly halfway between them? If not, which bond type is more similar to that of benzene, CC single or CC double bonds?
- 8.112 Average bond enthalpies are generally defined for gas-phase molecules. Many substances are liquids in their standard state. (Section 5.7) By using appropriate thermochemical data from Appendix C, calculate average bond enthalpies in the liquid state for the following bonds, and compare these values to the gas-phase values given in Table 8.4: (a) Br—Br, from Br₂(l); (b) C—Cl, from CCl₄(l); (c) O—O, from H₂O₂(l) (assume that the O—H bond enthalpy is the same as that in the gas phase). (d) Does the process of breaking bonds in the liquid as compared to the gas phase cost more energy? Explain the difference in the ΔH values between the two phases.
- 8.113 Silicon, the element, is the heart of integrated circuits and computer chips in almost all of our electronic devices. Si has the same structure as diamond; each atom is singly bonded to four neighbors. Unlike diamond, silicon has a tendency to oxidize (to SiO₂, another extended solid) if exposed to air.

 (a) Estimate the enthalpy of reaction for the conversion of 1 cm³ of silicon into SiO₂.
 (b) Unlike carbon, silicon rarely forms multiple bonds. Estimate the bond enthalpy of the Si=Si bond, assuming that the ratio of the Si=Si double bond enthalpy to that of the Si—Si single bond is the same as that for carbon–carbon bonds.

Design an Experiment

You have learned that the resonance of benzene, C₆H₆, gives the compound special stability.

(a) By using data in Appendix C, compare the heat of combustion of 1.0 mol $C_6H_6(g)$ to the heat of combustion of 3.0 mol acetylene, $C_2H_2(g)$. Which has the greater fuel value, 1.0 mol $C_6H_6(g)$ or 3.0 mol $C_2H_2(g)$? Are your calculations consistent with benzene being especially stable? (b) Repeat part (a), with the appropriate molecules, for toluene $(C_6H_5CH_3)$, a derivative of benzene that has a —CH₃ group in place of one H. (c) Another reaction you can use to compare molecules is *hydrogenation*, the reaction of a carbon-carbon double bond with H_2 to make a C—C single bond and two C—H single bonds. The experimental heat of hydrogenation of benzene to make cyclohexane $(C_6H_{12}$, a six-membered ring with 6 C—C single bonds with 12 C—H bonds) is 208 kJ/mol. The experimental heat of hydrogenation of cyclohexene $(C_6H_{10}$, a six-membered ring with one C=C double bond, 5 C—C single bonds, and 10 C—H bonds) to make cyclohexane is 120 kJ/mol. Show how these data can provide you with an estimate of the *resonance stabilization energy* of benzene. (d) Are the bond lengths or angles in benzene, compared to other hydrocarbons, sufficient to decide if benzene exhibits resonance and is especially stable? Discuss. (e) Consider cyclooctatetraene, C_8H_8 , which has the octagonal structure shown below.

Cyclooctatetraene

What experiments or calculations could you perform to determine whether cyclooctatetraene exhibits resonance?

Molecular Geometry and Bonding Theories

We saw in Chapter 8 that Lewis structures help us understand the compositions of molecules and their covalent bonds. However, Lewis structures do not show one of the most important aspects of molecules—their overall shapes. The shape and size of molecules—sometimes referred to as *molecular architecture*—are defined by the angles and distances between the nuclei of the component atoms.

The shape and size of a molecule of a substance, together with the strength and polarity of its bonds, largely determine the properties of that substance. Some of the most dramatic examples of the important roles of molecular architecture are seen in biochemical reactions. For example, the chapter-opening photograph shows a molecular model of atorvastatin, better known as Lipitor[®]. In the body, Lipitor inhibits the action of a key enzyme, called HMG-CoA reductase (we will discuss enzymes in Section 14.7). HMG-CoA reductase is a large complex biomolecule that is critical in the biochemical sequence that synthesizes cholesterol in the liver, and inhibition of its action leads to reduced cholesterol production. The molecules of Lipitor have two properties that lead to their pharmaceutical effectiveness: First, the molecule has the correct overall shape to fit perfectly in an important cavity in the HMG-CoA reductase enzyme, thus blocking that site from the molecules involved in cholesterol synthesis. Second, the molecule has the right atoms and arrangements of electrons to form strong interactions within the cavity, assuring that the Lipitor molecule will "stick" where it should. Thus, the drug action of Lipitor is largely a consequence of the shape and size of the molecule as well as the charge distributions within it. Even a small modification to molecular shape or size alters the drug's effectiveness.

► THE DRUG SHOWN HERE IS

ATORVASTATIN, better known by its trade name Lipitor. It is a member of a class of pharmaceuticals called *statins*, which lower blood cholesterol levels, thereby reducing the risk of heart attacks and strokes. Lipitor was first synthesized in 1985 by Bruce Roth of Warner-Lambert/Parke Davis (now part of Pfizer) and was approved for use in 1996. It is the best-selling drug in pharmaceutical history, with sales of more than \$125 billion from 1997 to 2011. It became available as a generic drug in 2011.

- **9.1 MOLECULAR SHAPES** We begin by discussing *molecular shapes* and examining some shapes commonly encountered in molecules.
- **9.2 THE VSEPR MODEL** We see how molecular geometries can be predicted using the *valence-shell electron-pair repulsion*, or *VSEPR*, model, which is based on Lewis structures and the repulsions between regions of high electron density.
- **9.3 MOLECULAR SHAPE AND MOLECULAR POLARITY** Once we know the geometry of a molecule and the types of bonds it

contains, we can determine whether the molecule is *polar* or *nonpolar*.

9.4 COVALENT BONDING AND ORBITAL OVERLAP

We explore how electrons are shared between atoms in a covalent bond. In *valence-bond theory*, the bonding electrons are visualized as originating in atomic orbitals on two atoms. A covalent bond is formed when these orbitals overlap.

9.5 HYBRID ORBITALS To account for molecular shape, we examine how the orbitals of one atom mix with one another, or *hybridize*, to create *hybrid orbitals*.

9.6 MULTIPLE BONDS Atomic orbitals that contribute to covalent bonding in a molecule can overlap in multiple ways to produce *sigma* and *pi* bonds between atoms. Single bonds consist of one sigma bond; multiple bonds involve one sigma and one or more pi bonds. We examine the geometric arrangements of these bonds and how they are exemplified in organic compounds.

9.7 MOLECULAR ORBITALS We examine a more sophisticated treatment of bonding called *molecular orbital theory*, which

introduces the concepts of bonding and antibonding molecular orbitals.

9.8 PERIOD 2 DIATOMIC MOLECULES We extend the concepts of molecular orbital theory to construct *energy-level diagrams* for second-row diatomic molecules.

As the example of Lipitor shows, molecular shape and size matter. In this chapter, our first goal is to understand the relationship between two-dimensional Lewis structures and three-dimensional molecular shapes. We will see the intimate relationship between the number of electrons involved in a molecule and the overall shape it adopts. Armed with this knowledge, we can examine more closely the nature of covalent bonds. The lines used to depict bonds in Lewis structures provide important clues about the orbitals that molecules use in bonding. By examining these orbitals, we can gain a greater understanding of the behavior of molecules. Mastering the material in this chapter will help you in later discussions of the physical and chemical properties of substances.

9.1 | Molecular Shapes

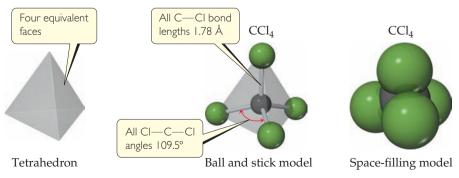

In Chapter 8 we used Lewis structures to account for the formulas of covalent compounds. ∞ (Section 8.5) Lewis structures, however, do not indicate the shapes of molecules; they simply show the number and types of bonds. For example, the Lewis structure of CCl_4 tells us only that four Cl atoms are bonded to a central C atom:

The Lewis structure is drawn with the atoms all in the same plane. As shown in ▼ Figure 9.1, however, the actual three-dimensional arrangement has the Cl atoms at the corners of a *tetrahedron*, a geometric object with four corners and four faces, each an equilateral triangle.

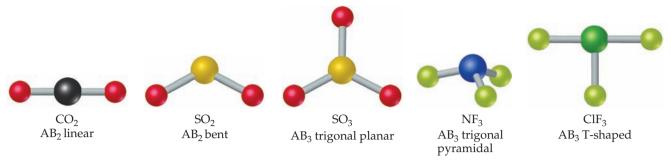

The shape of a molecule is determined by its **bond angles**, the angles made by the lines joining the nuclei of the atoms in the molecule. The bond angles of a molecule, together with the bond lengths ∞ (Section 8.8), define the shape and size of the molecule. In Figure 9.1, you should be able to see that there are six Cl—C—Cl bond angles in CCl₄, all of which have the same value. That bond angle, 109.5°, is characteristic of a tetrahedron. In addition, all four C—Cl bonds are of the same length (1.78 Å). Thus, the shape and size of CCl₄ are completely described by stating that the molecule is tetrahedral with C—Cl bonds of length 1.78 Å.

In the space-filling model, what determines the relative sizes of the spheres?

▲ Figure 9.1 Tetrahedral shape of CCI₄.

▲ Figure 9.2 Shapes of AB₂ and AB₃ molecules.

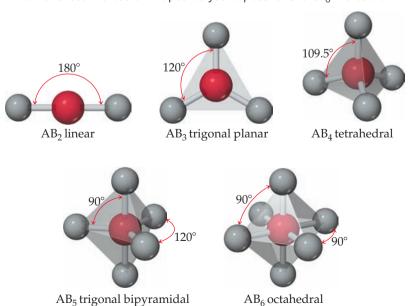

We begin our discussion of molecular shapes with molecules (and ions) that, like CCl_4 , have a single central atom bonded to two or more atoms of the same type. Such molecules have the general formula AB_n in which the central atom A is bonded to n B atoms. Both CO_2 and H_2O are AB_2 molecules, for example, whereas SO_3 and NH_3 are AB_3 molecules, and so on.

The number of shapes possible for AB_n molecules depends on the value of n. Those commonly found for AB_2 and AB_3 molecules are shown in \blacktriangle Figure 9.2. An AB_2 molecule must be either *linear* (bond angle = 180°) or *bent* (bond angle $\ne 180^\circ$). For AB_3 molecules, the two most common shapes place the B atoms at the corners of an equilateral triangle. If the A atom lies in the same plane as the B atoms, the shape is called *trigonal planar*. If the A atom lies above the plane of the B atoms, the shape is called *trigonal pyramidal* (a pyramid with an equilateral triangle as its base). Some AB_3 molecules, such as CIF_3 , are T-shaped, a relatively unusual shape shown in Figure 9.2. The atoms lie in one plane with two B - A - B angles of about 90° , and a third angle close to 180° .

Quite remarkably, the shapes of most AB_n molecules can be derived from just five basic geometric arrangements, shown in ∇ Figure 9.3. All of these are highly

▲ GO FIGURE

Which of these molecular shapes do you expect for the SF₆ molecule?

▲ Figure 9.3 Shapes allowing maximum distances between B atoms in AB_n molecules.

symmetric arrangements of the n B atoms around the central A atom. We have already seen the first three shapes: linear, trigonal planar, and tetrahedral. The trigonal bipyramid shape for AB₅ can be thought of as a trigonal planar AB₃ arrangement with two additional atoms, one above and one below the equilateral triangle. The octahedral shape for AB₆ has all six B atoms at the same distance from atom A with 90° B — A — B angles between all neighboring B atoms. Its symmetric shape (and its name) is derived from the *octahedron*, with eight faces, all of which are equilateral triangles.

You may have noticed that some of the shapes we have already discussed are *not* among the five shapes in Figure 9.3. For example, in Figure 9.2, neither the bent shape of the SO_2 molecule nor the trigonal pyramidal shape of the NF_3 molecule is among the shapes in Figure 9.3. However, as we soon will see, we can derive additional shapes, such as bent and trigonal pyramidal, by starting with one of our five basic arrangements. Starting with a tetrahedron, for example, we can remove atoms successively from the vertices, as shown in \blacktriangledown Figure 9.4. When an atom is removed from one vertex of a tetrahedron, the remaining AB_3 fragment has a trigonal-pyramidal geometry. When a second atom is removed, the remaining AB_2 fragment has a bent geometry.

Why do most AB_n molecules have shapes related to those shown in Figure 9.3? Can we predict these shapes? When A is a representative element (one from the s block or p block of the periodic table), we can answer these questions by using the **valence-shell electron-pair repulsion (VSEPR) model**. Although the name is rather imposing, the model is quite simple. It has useful predictive capabilities, as we will see in Section 9.2.

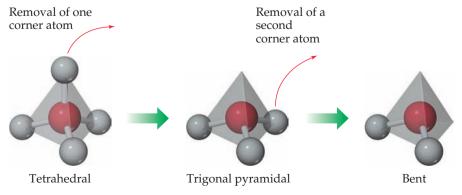

Give It Some Thought

In addition to tetrahedral, another common shape for AB_4 molecules is square planar. All five atoms lie in the same plane, with the B atoms at the corners of a square and the A atom at the center of the square. Which shape in Figure 9.3 could lead to a square-planar shape upon removal of one or more atoms?

In going from the tetrahedral shape to the bent shape, does it matter which two of the atoms we choose to remove?

▲ Figure 9.4 Derivatives of the tetrahedral molecular shape.

9.2 | The VSEPR Model

Imagine tying two identical balloons together at their ends. As shown in ▶ Figure 9.5, the two balloons naturally orient themselves to point away from each other; that is, they try to "get out of each other's way" as much as possible. If we add a third balloon, the balloons orient themselves toward the vertices of an equilateral triangle, and if we add a fourth balloon, they adopt a tetrahedral shape. We see that an optimum geometry exists for each number of balloons.

In some ways, the electrons in molecules behave like these balloons. We have seen that a single covalent bond is formed between two atoms when a pair of electrons occupies the space between the atoms. ∞ (Section 8.3) A bonding pair of electrons thus defines a region in which the electrons are most likely to be found. We will refer to such a region as an **electron domain**. Likewise, a nonbonding pair (or lone pair) of electrons, which was also discussed in Section 8.3, defines an electron domain that is located principally on one atom. For example, the Lewis structure of NH₃ has four electron domains around the central nitrogen atom (three bonding pairs, represented as usual by short lines, and one nonbonding pair, represented by dots):

Each multiple bond in a molecule also constitutes a single electron domain. Thus, the following resonance structure for O_3 has three electron domains around the central oxygen atom (a single bond, a double bond, and a nonbonding pair of electrons):

In general, each nonbonding pair, single bond, or multiple bond produces a single electron domain around the central atom in a molecule.

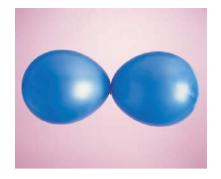

Give It Some Thought

Suppose a particular AB₃ molecule has the resonance structure

Does this structure follow the octet rule? How many electron domains are there around the A atom?

The VSEPR model is based on the idea that electron domains are negatively charged and therefore repel one another. Like the balloons in Figure 9.5, electron domains try to stay out of one another's way. The best arrangement of a given number of electron domains is the one that minimizes the repulsions among them. In fact, the analogy between electron domains and balloons is so close that the same preferred geometries are found in both cases. Like the balloons in Figure 9.5, two electron domains orient linearly, three domains orient in a trigonal-planar fashion, and four orient tetrahedrally. These arrangements, together with those for five- and six-electron domains, are summarized in Table 9.1. If you compare the geometries in Table 9.1 with those in Figure 9.3, you will see that they are the same. The shapes of different AB_n molecules or ions depend on the number of electron domains surrounding the central atom.

The arrangement of electron domains about the central atom of an AB_n molecule or ion is called its **electron-domain geometry**. In contrast, the **molecular geometry** is

Two balloons linear orientation

Three balloons trigonal-planar orientation

Four balloons tetrahedral orientation

▲ Figure 9.5 A balloon analogy for electron domains.

Table 9.1 Electron-Domain Geometries as a Function of Number of Electron Domains

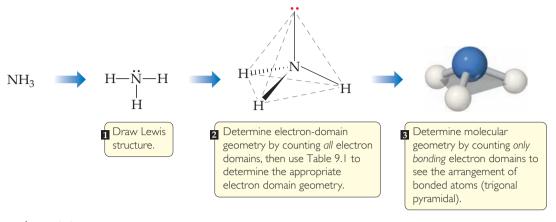

Number of Electron Domains	Arrangement of Electron Domains	Electron-Domain Geometry	Predicted Bond Angles
2 —	180° 120°	Linear	180°
3	120	Trigonal planar	120°
4	109.5°	Tetrahedral	109.5°
5 12	90°	Trigonal bipyramidal	120° 90°
6	90°	Octahedral	90°

the arrangement of *only the atoms* in a molecule or ion—any nonbonding pairs in the molecule are *not* part of the description of the molecular geometry.

In determining the shape of any molecule, we first use the VSEPR model to predict the electron-domain geometry. From knowing how many of the domains are due to nonbonding pairs, we can then predict the molecular geometry. When all the electron domains in a molecule arise from bonds, the molecular geometry is identical to the electron-domain geometry. When, however, one or more domains involve nonbonding pairs of electrons, we must remember that *the molecular geometry involves only electron domains due to bonds* even though the nonbonding pairs contribute to the electron-domain geometry.

We can generalize the steps we follow in using the VSEPR model to predict the shapes of molecules or ions:

1. Draw the Lewis structure of the molecule or ion (Section 8.5), and count the number of electron domains around the central atom. Each nonbonding electron

▲ Figure 9.6 Determining the molecular geometry of NH₃.

pair, each single bond, each double bond, and each triple bond counts as one electron domain.

- **2.** Determine the *electron-domain geometry* by arranging the electron domains about the central atom so that the repulsions among them are minimized, as shown in Table 9.1.
- **3.** Use the arrangement of the bonded atoms to determine the *molecular geometry*.
- ▲ Figure 9.6 shows how these steps are applied to predict the geometry of the NH₃ molecule. The three bonds and one nonbonding pair in the Lewis structure tell us we have four electron domains. Thus, from Table 9.1, the electron-domain geometry of NH₃ is tetrahedral. We know from the Lewis structure that one electron domain is due to a nonbonding pair, which occupies one of the four vertices of the tetrahedron. In determining the molecular geometry, we consider only the three N—H bond domains, which leads to a trigonal pyramidal geometry. The situation is just like the middle drawing in Figure 9.4 in which removing one atom from a tetrahedral molecule results in a trigonal pyramidal molecule. Notice that the tetrahedral arrangement of the four electron domains leads us to predict the trigonal-pyramidal molecular geometry.

Because the trigonal-pyramidal molecular geometry is based on a tetrahedral electron-domain geometry, the *ideal bond angles* are 109.5°. As we will soon see, bond angles deviate from ideal values when the surrounding atoms and electron domains are not identical.

Give It Some Thought

From the standpoint of the VSEPR model, what do nonbonding electron pairs, single bonds, and multiple bonds have in common?

As one more example, let's determine the shape of the ${\rm CO_2}$ molecule. Its Lewis structure reveals two electron domains (each one a double bond) around the central carbon:

Two electron domains orient in a linear electron-domain geometry (Table 9.1). Because neither domain is a nonbonding pair of electrons, the molecular geometry is also linear, and the O-C-O bond angle is 180° .

Table 9.2 summarizes the possible molecular geometries when an AB_n molecule has four or fewer electron domains about A. These geometries are important because they include all the shapes usually seen in molecules or ions that obey the octet rule.

Table 9.2 Electron-Domain and Molecular Geometries for Two, Three, and Four Electron Domains around a Central Atom

Number of Electron Domains	Electron- Domain Geometry	Bonding Domains	Nonbonding Domains	Molecular Geometry	Example
2	Linear	2	0	Linear	Ö=c=Ö
3	Trigonal planar	3	0	Trigonal planar	:F: :F: B :F:
		2	1	Bent	
4	Tetrahedral	4	0	Tetrahedral	H HWLC H H
		3	1	Trigonal	H ^W H H
		2	2	pyramidal Bent	H ^{wr}

SAMPLE EXERCISE 9.1 Using the VSEPR Model

Use the VSEPR model to predict the molecular geometry of (a) O₃, (b) SnCl₃⁻.

SOLUTION

Analyze We are given the molecular formulas of a molecule and a polyatomic ion, both conforming to the general formula AB_n and both having a central atom from the p block of the periodic table. (Notice that for O_3 , the A and B atoms are all oxygen atoms.)

Plan To predict the molecular geometries, we draw their Lewis structures and count electron domains around the central atom to get the electron-domain geometry. We then obtain the molecular geometry from the arrangement of the domains that are due to bonds.

Solve

(a) We can draw two resonance structures for O₃:

Because of resonance, the bonds between the central O atom and the outer O atoms are of equal length. In both resonance structures the central O atom is bonded to the two outer O atoms and has one non-bonding pair. Thus, there are three electron domains about the central O atoms. (Remember that a double bond counts as a single electron domain.) The arrangement of three electron domains is trigonal planar (Table 9.1). Two of the domains are from bonds, and one is due to a nonbonding pair. So, the molecular geometry is bent with an ideal bond angle of 120° (Table 9.2).

Comment As this example illustrates, when a molecule exhibits resonance, any one of the resonance structures can be used to predict the molecular geometry.

(b) The Lewis structure for SnCl₃⁻ is

The central Sn atom is bonded to the three Cl atoms and has one nonbonding pair; thus, we have four electron domains, meaning a tetrahedral electron-domain geometry (Table 9.1) with one vertex occupied by a nonbonding pair of electrons. A tetrahedral electron-domain geometry with three bonding and one nonbonding domains leads to a trigonal-pyramidal molecular geometry (Table 9.2).

Practice Exercise 1

Consider the following AB_3 molecules and ions: PCl_3 , SO_3 , $AlCl_3$, SO_3^{2-} , and CH_3^+ . How many of these molecules and ions do you predict to have a trigonal-planar molecular geometry?

$$\vdots \ddot{\bigcirc} - \ddot{\bigcirc} = \ddot{\bigcirc} \longleftrightarrow \ddot{\bigcirc} = \ddot{\bigcirc} - \ddot{\bigcirc} \colon$$

Practice Exercise 2

Predict the electron-domain and molecular geometries for (a) SeCl₂, (b) CO₃²⁻.

Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles

We can refine the VSEPR model to explain slight distortions from the ideal geometries summarized in Table 9.2. For example, consider methane (CH_4) , ammonia (NH_3) , and water (H_2O) . All three have a tetrahedral electron-domain geometry, but their bond angles differ slightly:

Notice that the bond angles decrease as the number of nonbonding electron pairs increases. A bonding pair of electrons is attracted by both nuclei of the bonded atoms, but a nonbonding pair is attracted primarily by only one nucleus. Because a nonbonding pair experiences less nuclear attraction, its electron domain is spread out more in space than is the electron domain for a bonding pair (Figure 9.7). Nonbonding electron pairs therefore take up more space than bonding pairs; in essence, they act as larger and fatter balloons in our analogy of Figure 9.5. As a result, electron domains for nonbonding electron pairs exert greater repulsive forces on adjacent electron domains and tend to compress bond angles.

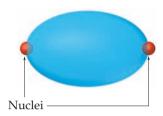

Because multiple bonds contain a higher electronic-charge density than single bonds, multiple bonds also represent enlarged electron domains. Consider the Lewis structure of *phosgene*, Cl₂CO:

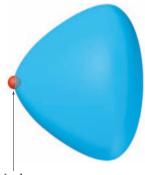

GO FIGURE

Why is the volume occupied by the nonbonding electron pair domain larger than the volume occupied by the bonding domain?

Bonding electron pair

Nonbonding pair

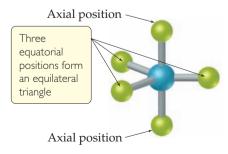

Nucleus

▲ Figure 9.7 Relative volumes occupied by bonding and nonbonding electron domains.

GO FIGURE

What is the bond angle formed by an axial atom, the central atom, and any equatorial atom?

▲ Figure 9.8 In a trigonal-bipyramidal geometry, there are two types of positions for the outer atoms.

Because three electron domains surround the central atom, we might expect a trigonal-planar geometry with 120° bond angles. The double bond, however, seems to act much like a nonbonding pair of electrons, reducing the Cl—C—Cl bond angle to 111.4°:

In general, electron domains for multiple bonds exert a greater repulsive force on adjacent electron domains than do electron domains for single bonds.

Give It Some Thought

One resonance structure of the nitrate ion is

The bond angles in this ion are 120°. Is this observation consistent with the preceding discussion of the effect of multiple bonds on bond angles?

Molecules with Expanded Valence Shells

Atoms from period 3 and beyond may be surrounded by more than four electron pairs. (Section 8.7) Molecules with five or six electron domains around the central atom have molecular geometries based on either a *trigonal-bipyramidal* (five domains) or *octahedral* (six domains) electron-domain geometry (Table 9.3).

The most stable electron-domain geometry for five electron domains is the trigonal bipyramid (two trigonal pyramids sharing a base). Unlike the other arrangements we have seen, the electron domains in a trigonal bipyramid can point toward two geometrically distinct types of positions. Two domains point toward *axial positions* and three point toward *equatorial positions* (◀ Figure 9.8). Each axial domain makes a 90° angle with any equatorial domain. Each equatorial domain makes a 120° angle with either of the other two equatorial domains and a 90° angle with either axial domain.

Suppose a molecule has five electron domains, and there are one or more non-bonding pairs. Will the domains from the nonbonding pairs occupy axial or equatorial positions? To answer this question, we must determine which location minimizes repulsion between domains. Repulsion between two domains is much greater when they are situated 90° from each other than when they are at 120°. An equatorial domain is 90° from only two other domains (the axial domains), but an axial domain is 90° from *three* other domains (the equatorial domains). Hence, an equatorial domain experiences less repulsion than an axial domain. Because the domains from nonbonding pairs exert larger repulsions than those from bonding pairs, nonbonding domains *always* occupy the equatorial positions in a trigonal bipyramid.

Give It Some Thought

It might seem that a square-planar geometry of four electron domains around a central atom would be more favorable than a tetrahedron. Can you rationalize why the tetrahedron is preferred, based on angles between electron domains?

The most stable electron-domain geometry for six electron domains is the *octahedron*. An octahedron is a polyhedron with six vertices and eight faces, each an equilateral triangle. An atom with six electron domains around it can be visualized as being at the center of the octahedron with the electron domains pointing toward the six vertices, as

Table 9.3 Electron-Domain and Molecular Geometries for Five and Six Electron Domains around a Central Atom

Number of Electron Domains	Electron- Domain Geometry	Bonding Domains	Nonbonding Domains	Molecular Geometry	Example
5	Trigonal	5	0	Trigonal bipyramidal	PCl ₅
	bipyramidal	4	1	Seesaw	SF ₄
		3	2	T-shaped	ClF ₃
		2	3	Linear	XeF ₂
6	Octahedral	6	0	Octahedral	SF ₆
		5	1		${ m BrF}_5$
		4	2	Square pyramidal Square planar	XeF ₄

shown in Table 9.3. All the bond angles are 90°, and all six vertices are equivalent. Therefore, if an atom has five bonding electron domains and one nonbonding domain, we can put the nonbonding domain at any of the six vertices of the octahedron. The result is always a square-pyramidal molecular geometry. When there are two nonbonding electron domains, however, their repulsions are minimized by pointing them toward opposite sides of the octahedron, producing a square-planar molecular geometry, as shown in Table 9.3.

SAMPLE

EXERCISE 9.2 Molecular Geometries of Molecules with Expanded Valence Shells

Use the VSEPR model to predict the molecular geometry of (a) SF₄, (b) IF₅.

SOLUTION

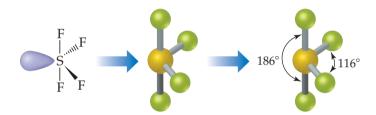

Analyze The molecules are of the AB_n type with a central p-block atom.

Plan We first draw Lewis structures and then use the VSEPR model to determine the electron-domain geometry and molecular geometry.

(a) The Lewis structure for SF₄ is

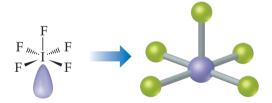

The sulfur has five electron domains around it: four from the S—F bonds and one from the nonbonding pair. Each domain points toward a vertex of a trigonal bipyramid. The domain from the nonbonding pair will point toward an equatorial position. The four bonds point toward the remaining four positions, resulting in a molecular geometry that is described as seesaw-shaped:

Comment The experimentally observed structure is shown on the right. We can infer that the nonbonding electron domain occupies an equatorial position, as predicted. The axial and equatorial S — F bonds are slightly bent away from the nonbonding domain, suggesting that the bonding domains are "pushed" by the nonbonding domain, which exerts a greater repulsion (Figure 9.7).

(b) The Lewis structure of IF₅ is

The iodine has six electron domains around it, one of which is nonbonding. The electron-domain geometry is therefore octahedral, with one position occupied by the nonbonding pair, and the molecular geometry is *square pyramidal* (Table 9.3):

Comment Because the nonbonding domain is larger than the bonding domains, we predict that the four F atoms in the base of the pyramid will be tipped up slightly toward the top F atom. Experimentally, we find that the angle between the base atoms and the top F atom is 82°, smaller than the ideal 90° angle of an octahedron.

Practice Exercise 1

A certain AB₄ molecule has a square-planar molecular geometry. Which of the following statements about the molecule is or are

- (i) The molecule has four electron domains about the central atom A.
- (ii) The B—A—B angles between neighboring B atoms is 90°.
- (iii) The molecule has two nonbonding pairs of electrons on atom A.

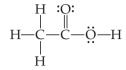

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

Practice Exercise 2

Predict the electron-domain and molecular geometries of (a) BrF₃, **(b)** SF_5^+ .

Shapes of Larger Molecules

Although the molecules and ions we have considered contain only a single central atom, the VSEPR model can be extended to more complex molecules. Consider the acetic acid molecule, for example:

We can use the VSEPR model to predict the geometry about each atom:

	H H—C—— H	:0: C	—— <u>Ö</u> —н
Number of electron domains	4	3	4
Electron-domain geometry	Tetrahedral	Trigonal planar	Tetrahedral
Predicted bond angles	109.5°	120°	109.5°

The C on the left has four electron domains (all bonding), so the electron-domain and molecular geometries around that atom are both tetrahedral. The central C has three electron domains (counting the double bond as one domain), making both the electron-domain and the molecular geometries trigonal planar. The O on the right has four electron domains (two bonding, two nonbonding), so its electron-domain geometry is tetrahedral and its molecular geometry is bent. The bond angles about the central C atom and the O atom are expected to deviate slightly from the ideal values of 120° and 109.5° because of the spatial demands of multiple bonds and nonbonding electron pairs.

Our analysis of the acetic acid molecule is shown in ▶ Figure 9.9.

SAMPLE EXERCISE 9.3 Predicting Bond Angles

Eyedrops for dry eyes usually contain a water-soluble polymer called *poly(vinyl alcohol)*, which is based on the unstable organic molecule *vinyl alcohol*:

Predict the approximate values for the H - O - C and O - C - C bond angles in vinyl alcohol.

SOLUTION

Analyze We are given a Lewis structure and asked to determine two bond angles.

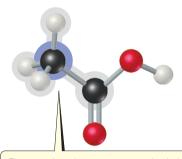

Plan To predict a bond angle, we determine the number of electron domains surrounding the middle atom in the bond. The ideal angle corresponds to the electron-domain geometry around the atom. The angle will be compressed somewhat by nonbonding electrons or multiple bonds.

Solve In H—O—C, the O atom has four electron domains (two bonding, two nonbonding). The electron-domain geometry around O is therefore tetrahedral, which gives an ideal angle of 109.5°. The H—O—C angle is compressed somewhat by the nonbonding pairs, so we expect this angle to be slightly less than 109.5°.

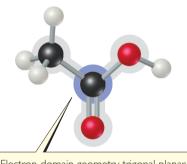

To predict the O-C-C bond angle, we examine the middle atom in the angle. In the molecule, there are three atoms bonded to this C atom and no nonbonding pairs, and so it has three electron domains about it. The predicted electron-domain geometry is trigonal planar, resulting in an ideal bond angle of 120° . Because of the larger size of the C-C domain, the bond angle should be slightly greater than 120° .

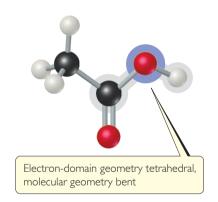

In the actual structure of acetic acid, which bond angle is expected to be the smallest?

Electron-domain geometry tetrahedral, molecular geometry tetrahedral

Electron-domain geometry trigonal planar, molecular geometry trigonal planar

▲ Figure 9.9 The electron-domain and molecular geometries around the three central atoms of acetic acid, CH₃COOH.

Practice Exercise 1

The atoms of the compound methylhydrazine, CH_6N_2 , which is used as a rocket propellant, are connected as follows (note that lone pairs are not shown):

What do you predict for the ideal values of the C-N-N and H-N-H angles, respectively? (a) 109.5° and 109.5° (b) 109.5° and 120° (c) 120° and 109.5° (d) 120° and 120° (e) None of the above

Practice Exercise 2

Predict the H—C—H and C—C—C bond angles in *propyne*:

9.3 | Molecular Shape and Molecular Polarity

Now that we have a sense of the shapes that molecules adopt and why they do so, we will return to some topics that we first discussed in Section 8.4, namely, *bond polarity* and *dipole moments*. Recall that bond polarity is a measure of how equally the electrons in a bond are shared between the two atoms of the bond. As the difference in electronegativity between the two atoms increases, so does the bond polarity. ∞ (Section 8.4)

We saw that the dipole moment of a diatomic molecule is a measure of the amount of charge separation in the molecule.

For a molecule consisting of more than two atoms, the dipole moment depends on both the polarities of the individual bonds and the geometry of the molecule. For each bond in the molecule, we consider the **bond dipole**, which is the dipole moment due only to the two atoms in that bond. Consider the linear CO_2 molecule, for example. As shown in \P Figure 9.10, each C = O bond is polar, and because the C = O bonds are identical, the bond dipoles are equal in magnitude. A plot of the molecule's electron density clearly shows that the individual bonds are polar, but what can we say about the *overall* dipole moment of the molecule?

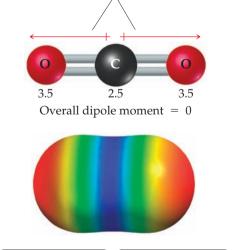

Bond dipoles and dipole moments are *vector quantities*; that is, they have both a magnitude and a direction. The dipole moment of a polyatomic molecule is the vector sum of its bond dipoles. Both the magnitudes *and* the directions of the bond dipoles must be considered when summing vectors. The two bond dipoles in CO_2 , although equal in magnitude, are opposite in direction. Adding them is the same as adding two numbers that are equal in magnitude but opposite in sign, such as 100 + (-100). The bond dipoles, like the numbers, "cancel" each other. Therefore, the dipole moment of CO_2 is zero, even though the individual bonds are polar. The geometry of the molecule dictates that the overall dipole moment be zero, making CO_2 a *nonpolar* molecule.

Now let's consider H_2O , a bent molecule with two polar bonds (\triangleright Figure 9.11). Again, the two bonds are identical, and the bond dipoles are equal in magnitude. Because the molecule is bent, however, the bond dipoles do not directly oppose each other and therefore do not cancel. Hence, the H_2O molecule has an overall nonzero dipole moment ($\mu = 1.85\,D$) and is therefore a *polar* molecule. The oxygen atom carries a partial negative charge, and the hydrogen atoms each have a partial positive charge, as shown in the electron-density model.

▲ GO FIGURE

What is the sum of the two red vectors at the top of the figure?

Equal and oppositely directed bond dipoles

High electron density

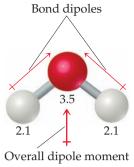

Low electron density

Low electron density

Give It Some Thought

The molecule O=C=S is linear and has a Lewis structure analogous to that of CO₂. Would you expect this molecule to be nonpolar?

Figure 9.12 shows some examples of polar and nonpolar molecules, all with polar bonds. The molecules in which the central atom is symmetrically surrounded by identical atoms (BF₃ and CCl₄) are nonpolar. For AB_n molecules in which all the B atoms are the same, certain symmetrical shapes—linear (AB₂), trigonal planar (AB₃), tetrahedral and square planar (AB₄), trigonal bipyramidal (AB₅), and octahedral (AB₆)—must lead to nonpolar molecules even though the individual bonds might be polar.

High electron density

SAMPLE EXERCISE 9.4 Polarity of Molecules

Predict whether these molecules are polar or nonpolar: (a) BrCl, (b) SO₂, (c) SF₆.

SOLUTION

Analyze We are given three molecular formulas and asked to predict whether the molecules are polar.

Plan A molecule containing only two atoms is polar if the atoms differ in electronegativity. The polarity of a molecule containing three or more atoms depends on both the molecular geometry and the individual bond polarities. Thus, we must draw a Lewis structure for each molecule containing three or more atoms and determine its molecular geometry. We then use electronegativity values to determine the direction of the bond dipoles. Finally, we see whether the bond dipoles cancel to give a nonpolar molecule or reinforce each other to give a polar one.

Solve

(a) Chlorine is more electronegative than bromine. All diatomic molecules with polar bonds are polar molecules. Consequently, BrCl is polar, with chlorine carrying the partial negative charge:

$$+$$
 Br—Cl

The measured dipole moment of BrCl is $\mu = 0.57$ D.

(b) Because oxygen is more electronegative than sulfur, SO_2 has polar bonds. Three resonance forms can be written:

$$\vdots \ddot{\bigcirc} - \ddot{\mathbf{S}} = \dot{\bigcirc} \vdots \longleftrightarrow \vdots \dot{\bigcirc} = \ddot{\mathbf{S}} = \dot{\bigcirc} \vdots \longleftrightarrow \vdots \dot{\bigcirc} = \ddot{\mathbf{S}} = \dot{\Diamond} \vdots$$

For each of these, the VSEPR model predicts a bent molecular geometry. Because the molecule is bent, the bond dipoles do not cancel, and the molecule is polar:

Experimentally, the dipole moment of SO_2 is $\mu = 1.63$ D.

(c) Fluorine is more electronegative than sulfur, so the bond dipoles point toward fluorine. For clarity, only one S — F dipole is shown. The six S — F bonds are arranged octahedrally around the central sulfur:

$$F \xrightarrow{F} S \xrightarrow{F} F$$

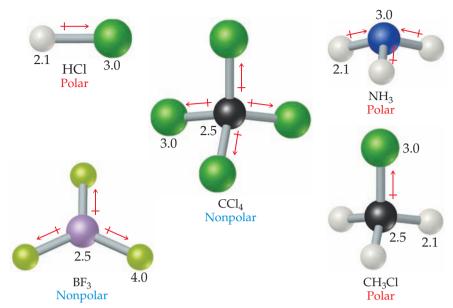

Because the octahedral molecular geometry is symmetrical, the bond dipoles cancel, and the molecule is nonpolar, meaning that $\mu=0$.

Practice Exercise 1

Consider an AB_3 molecule in which A and B differ in electronegativity. You are told that the molecule has an overall dipole moment of zero. Which of the following could be the molecular geometry of the molecule? (a) Trigonal pyramidal (b) Trigonal planar (c) T-shaped (d) Tetrahedral (e) More than one of the above

Practice Exercise 2

Determine whether the following molecules are polar or nonpolar: (a) SF₄, (b) SiCl₄.

▲ Figure 9.12 Polar and nonpolar molecules containing polar bonds. The numbers are electronegativity values.

9.4 | Covalent Bonding and Orbital Overlap

The VSEPR model provides a simple means for predicting molecular geometries but does not explain why bonds exist between atoms. In developing theories of covalent bonding, chemists have approached the problem from another direction, using quantum mechanics. How can we use atomic orbitals to explain bonding and to account for molecular geometries? The marriage of Lewis's notion of electronpair bonds and the idea of atomic orbitals leads to a model of chemical bonding, called **valence-bond theory**, in which bonding electron pairs are concentrated in the regions between atoms, and nonbonding electron pairs lie in directed regions of space. By extending this approach to include the ways in which atomic orbitals can mix with one another, we obtain an explanatory picture that corresponds to the VSEPR model.

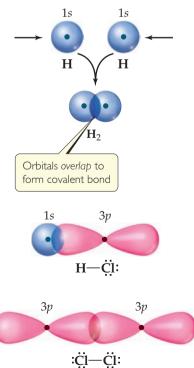

In Lewis theory, covalent bonding occurs when atoms share electrons because the sharing concentrates electron density between the nuclei. In valence-bond theory, we visualize the buildup of electron density between two nuclei as occurring when a valence atomic orbital of one atom shares space, or *overlaps*, with a valence atomic orbital of another atom. The overlap of orbitals allows two electrons of opposite spin to share the space between the nuclei, forming a covalent bond.

◀ Figure 9.13 shows three examples of how valence-bond theory describes the coming together of two atoms to form a molecule. In the example of the formation of H_2 , each hydrogen atom has a single electron in a 1s orbital. As the orbitals overlap, electron density is concentrated between the nuclei. Because the electrons in the overlap region are simultaneously attracted to both nuclei, they hold the atoms together, forming a covalent bond.

The idea of orbital overlap producing a covalent bond applies equally well to other molecules. In HCl, for example, chlorine has the electron configuration [Ne] $3s^23p^5$. All the valence orbitals of chlorine are full except one 3p orbital, which contains a single electron. This 3p electron pairs with the single 1s electron of H to form the covalent bond that holds HCl together (Figure 9.13). Because the other two chlorine 3p orbitals are already filled with a pair of electrons, they do not participate in the bonding to hydrogen. Likewise, we can explain the covalent bond in Cl_2 in terms of the overlap of the singly occupied 3p orbital of one Cl atom with the singly occupied 3p orbital of another.

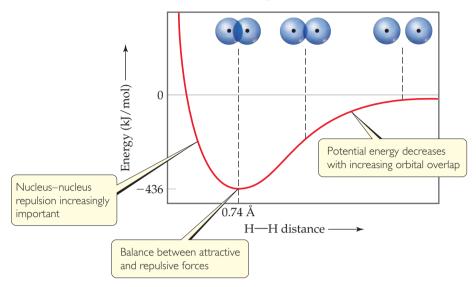

How does the notion of overlap explain why the bond in HCl is longer than the bond in H_2 ?

▲ Figure 9.13 Covalent bonds in H₂, HCl, and Cl₂ result from overlap of atomic orbitals.

On the left part of the curve the potential energy rises above zero. What causes this to happen?

▲ Figure 9.14 Formation of the H_2 molecule as atomic orbitals overlap.

There is always an optimum distance between the two nuclei in any covalent bond. ▲ Figure 9.14 shows how the potential energy of a system consisting of two H atoms changes as the atoms come together to form an H₂ molecule. When the atoms are infinitely far apart, they do not "feel" each other and so the energy approaches zero. As the distance between the atoms decreases, the overlap between their 1s orbitals increases. Because of the resultant increase in electron density between the nuclei, the potential energy of the system decreases. That is, the strength of the bond increases, as shown by the decrease in the potential energy of the two-atom system. However, Figure 9.14 also shows that the energy increases sharply when the distance between the two hydrogen nuclei is less than 0.74 Å. The increase in potential energy of the system, which becomes significant at short internuclear distances, is due mainly to the electrostatic repulsion between the nuclei. The internuclear distance at the minimum of the potential-energy curve (in this example, at 0.74 Å) corresponds to the bond length of the molecule. The potential energy at this minimum corresponds to the bond strength. Thus, the observed bond length is the distance at which the attractive forces between unlike charges (electrons and nuclei) are balanced by the repulsive forces between like charges (electron-electron and nucleus-nucleus).

9.5 | **Hybrid Orbitals**

The VSEPR model, simple as it is, does a surprisingly good job at predicting molecular shape, despite the fact that it has no obvious relationship to the filling and shapes of atomic orbitals. For example, we would like to understand how to account for the tetrahedral arrangement of C—H bonds in methane in terms of the 2s and 2p orbitals of the central carbon atom, which are not directed toward the apices of a tetrahedron. How can we reconcile the notion that covalent bonds are formed from overlap of atomic orbitals with the molecular geometries that come from the VSEPR model?

To begin with, we recall that atomic orbitals are mathematical functions that come from the quantum mechanical model for atomic structure. ∞ (Section 6.5) To explain molecular geometries, we often assume that the atomic orbitals on an atom (usually the central atom) mix to form new orbitals called **hybrid orbitals**. The shape of any hybrid orbital is different from the shapes of the original atomic orbitals. The process of mixing atomic orbitals is a mathematical operation called **hybridization**. The total number of atomic orbitals on an atom remains constant, so the number of hybrid orbitals on an atom equals the number of atomic orbitals that are mixed.

As we examine the common types of hybridization, notice the connection between the type of hybridization and some of the molecular geometries predicted by the VSEPR model: linear, bent, trigonal planar, and tetrahedral.

sp Hybrid Orbitals

To illustrate the process of hybridization, consider the BeF_2 molecule, which has the Lewis structure

The VSEPR model correctly predicts that BeF₂ is linear with two identical Be—F bonds. How can we use valence-bond theory to describe the bonding? The electron configuration of F $(1s^22s^22p^5)$ indicates an unpaired electron in a 2p orbital. This electron can be paired with an unpaired Be electron to form a polar covalent bond. Which orbitals on the Be atom, however, overlap with those on the F atoms to form the Be—F bonds?

The orbital diagram for a ground-state Be atom is

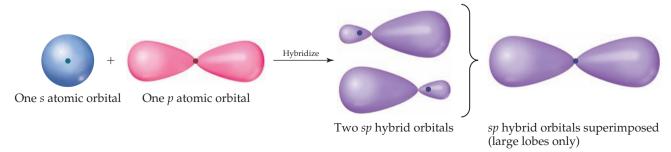

Because it has no unpaired electrons, the Be atom in its ground state cannot bond with the fluorine atoms. The Be atom could form two bonds, however, by envisioning that we "promote" one of the 2*s* electrons to a 2*p* orbital:

The Be atom now has two unpaired electrons and can therefore form two polar covalent bonds with F atoms. The two bonds would not be identical, however, because a Be 2s orbital would be used to form one of the bonds and a 2p orbital would be used to form the other. Therefore, although the promotion of an electron allows two Be—F bonds to form, we still have not explained the structure of BeF₂.

We can solve this dilemma by "mixing" the 2s orbital with one 2p orbital to generate two new orbitals, as shown in ∇ Figure 9.15. Like p orbitals, each new orbital has two lobes. Unlike p orbitals, however, one lobe is much larger than the other. The two new orbitals are identical in shape, but their large lobes point in opposite directions. These two new orbitals, which are shown in purple in Figure 9.15, are hybrid orbitals. Because we have hybridized one s and one p orbital, we call each hybrid an sp hybrid orbital. According to the valence-bond model, a linear arrangement of electron domains implies sp hybridization.

For the Be atom of BeF₂, we write the orbital diagram for the formation of two *sp* hybrid orbitals as

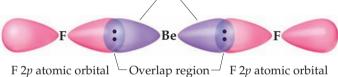

The electrons in the sp hybrid orbitals can form bonds with the two fluorine atoms (∇ Figure 9.16). Because the sp hybrid orbitals are equivalent but point in opposite directions, BeF₂ has two identical bonds and a linear geometry. We have used one of the 2p orbitals in making the hybrids; the remaining two 2p atomic orbitals of Be remain unhybridized and are vacant. Remember also that each fluorine atom has two other valence p atomic orbitals, each containing one nonbonding electron pair. Those atomic orbitals are omitted from Figure 9.16 to keep the illustration simpler.

GO FIGURE

Why is it reasonable to take account of only the large lobes of the Be hybrid orbitals in considering the bonding to F?

Large lobes from two Be *sp* hybrid orbitals

▲ Figure 9.16 Formation of two equivalent Be — F bonds in BeF₂.

Give It Some Thought

What is the orientation of the two unhybridized p orbitals on Be with respect to the two Be — F bonds?

sp² and sp³ Hybrid Orbitals

Whenever we mix a certain number of atomic orbitals, we get the same number of hybrid orbitals. Each hybrid orbital is equivalent to the others but points in a different direction. Thus, mixing one 2s and one 2p atomic orbital yields two equivalent sp hybrid orbitals that point in opposite directions (Figure 9.15). Other combinations of atomic orbitals can be hybridized to obtain different geometries. In BF₃, for example, mixing the 2s and two of the 2p atomic orbitals yields three equivalent sp^2 (pronounced "s-p-two") hybrid orbitals (Figure 9.17).

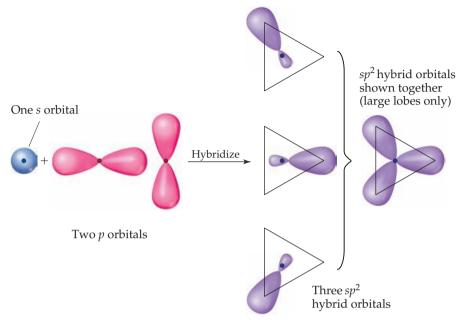

The three sp^2 hybrid orbitals lie in the same plane, 120° apart from one another. They are used to make three equivalent bonds with the three fluorine atoms, leading to the trigonal-planar molecular geometry of BF₃. Notice that an unfilled 2p atomic orbital remains unhybridized; it is oriented perpendicular to the plane defined by the three sp^2 hybrid orbitals, with one lobe above and one below the plane. This unhybridized orbital will be important when we discuss double bonds in Section 9.6.

An s atomic orbital can mix with all three p atomic orbitals in the same subshell. For example, the carbon atom in CH_4 forms four equivalent bonds with the four hydrogen atoms. We envision this process as resulting from the mixing of the 2s and all three 2p atomic orbitals of carbon to create four equivalent sp^3 (pronounced "s-p-three") hybrid orbitals. Each sp^3 hybrid orbital has a large lobe that

GO FIGURE

What is the angle formed between the large lobes of the three sp^2 hybrid orbitals?

▲ Figure 9.17 Formation of sp² hybrid orbitals.

points toward one vertex of a tetrahedron (> Figure 9.18). These hybrid orbitals can be used to form two-electron bonds by overlap with the atomic orbitals of another atom, such as H. Using valence-bond theory, we can describe the bonding in CH₄ as the overlap of four equivalent sp^3 hybrid orbitals on C with the 1s orbitals of the four H atoms to form four equivalent bonds.

Give It Some Thought

In an sp^2 hybridized atom, we saw that there was one unhybridized 2p orbital. How many unhybridized 2p orbitals remain on an atom that has sp^3 hybrid orbitals?

The idea of hybridization is also used to describe the bonding in molecules containing nonbonding pairs of electrons. In H₂O, for example, the electron-domain geometry around the central O atom is approximately tetrahedral (Figure 9.19). Thus, the four electron pairs can be envisioned as occupying sp^3 hybrid orbitals. Two of the hybrid orbitals contain nonbonding pairs of electrons, and the other two form bonds with the hydrogen atoms.

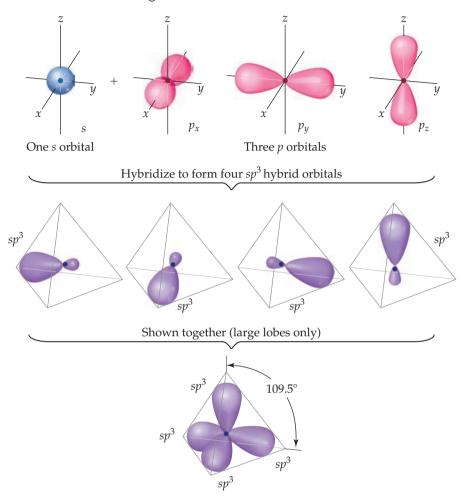

Hypervalent Molecules

So far our discussion of hybridization has extended only to period 2 elements, specifically carbon, nitrogen, and oxygen. The elements of period 3 and beyond introduce a new consideration because in many of their compounds these elements are hypervalent—they have more than an octet of electrons around the central atom. ∞ (Section 8.7) We saw in Section 9.2 that the VSEPR model works well to predict the geometries of hypervalent molecules such as PCl₅, SF₆, or BrF₅. But can we extend the use of hybrid orbitals to describe the bonding in these molecules? In short, the answer to this question is that it is best *not* to use hybrid orbitals for hypervalent molecules, as we now briefly discuss.

The valence-bond model we developed for period 2 elements works well for compounds of period 3 elements so long as we have no more than an octet of electrons in

GO FIGURE

Which of the p orbitals do you think contributes the most in the mixing that leads to the right-most sp^3 hybrid orbital in the second row of the figure?

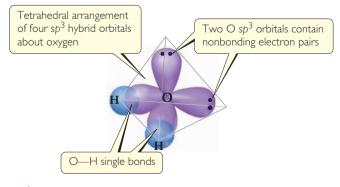

▲ Figure 9.18 Formation of sp³ hybrid orbitals.

the valence-shell orbitals. Thus, for example, it is appropriate to discuss the bonding in PF_3 or H_2Se in terms of hybridized s and p orbitals on the central atom.

For compounds with more than an octet, we could imagine increasing the number of hybrid orbitals formed by including valence-shell d orbitals. For example, for SF₆ we could envision mixing in two sulfur 3d orbitals in addition to the 3s and three 3p orbitals to make a total of six hybrid orbitals. However, the sulfur 3d orbitals are substantially higher in energy than the 3s and 3p orbitals, so the amount of energy needed to form the six hybrid orbitals is greater than the amount returned by forming bonds with the six fluorine atoms. Theoretical calculations suggest that the sulfur 3d orbitals do not participate to a significant degree in the bonding between sulfur and the six fluorine atoms, and that it would not be valid to describe the bonding in SF₆ in terms of six hybrid orbitals. The more detailed bonding model needed to discuss the bonding in SF₆ and other hypervalent molecules requires a treatment beyond the scope of a general chemistry text. Fortu-

Does it matter which of the two sp^3 hybrid orbitals are used to hold the two nonbonding electron pairs?

▲ Figure 9.19 Hybrid orbital description of H₂O.

nately, the VSEPR model, which explains the geometrical properties of such molecules in terms of electrostatic repulsions, does a good job of predicting their geometries.

This discussion reminds us that models in science are not reality but rather are our attempts to describe aspects of reality that we have been able to measure, such as bond distances, bond energies, molecular geometries, and so on. A model may work well up to a certain point but not beyond it, as is the case for hybrid orbitals. The hybrid orbital model for period 2 elements has proven very useful and is an essential part of any modern discussion of bonding and molecular geometry in organic chemistry. When it comes to molecules such as SF₆, however, we encounter the limitations of the model.

Hybrid Orbital Summary

Overall, hybrid orbitals provide a convenient model for using valence-bond theory to describe covalent bonds in molecules that have an octet or less of electrons around the central atom and in which the molecular geometry conforms to the electron-domain geometry predicted by the VSEPR model. While the concept of hybrid orbitals has limited predictive value, when we know the electron-domain geometry, we can employ hybridization to describe the atomic orbitals used by the central atom in bonding.

The following steps allow us to describe the hybrid orbitals used by an atom in bonding:

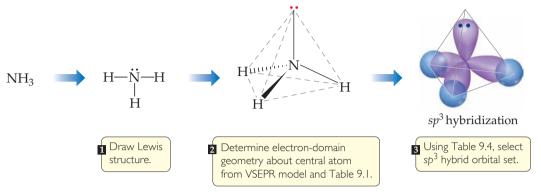

- 1. Draw the *Lewis structure* for the molecule or ion.
- **2.** Use the VSEPR model to determine the electron-domain geometry around the central atom.
- **3.** Specify the *hybrid orbitals* needed to accommodate the electron pairs based on their geometric arrangement (▼ Table 9.4).

These steps are illustrated in \triangleright Figure 9.20, which shows how the hybridization at N in NH₃ is determined.

Table 9.4 Geometric Arrangements Characteristic of Hybrid Orbital Sets Hybrid Atomic **Orbital Set Orbital Set** Geometry Examples 180° Two sp BeF₂, HgCl₂ s,p Linear Three sv^2 BF₃, SO₃ s,p,p120° Trigonal planar 109.5 Four sp³ CH₄, NH₃, H₂O, NH₄⁺ s,p,p,pTetrahedral

SAMPLE EXERCISE 9.5 Describing the Hybridization of a Central Atom

Describe the orbital hybridization around the central atom in NH₂⁻.

SOLUTION

Analyze We are given the chemical formula for a polyatomic anion and asked to describe the type of hybrid orbitals surrounding the central atom.

Plan To determine the central atom hybrid orbitals, we must know the electron-domain geometry around the atom. Thus, we draw the Lewis structure to determine the number of electron domains around the central atom. The hybridization conforms to the number and geometry of electron domains around the central atom as predicted by the VSEPR model.

Solve The Lewis structure is

Because there are four electron domains around N, the electron-domain geometry is tetrahedral. The hybridization that gives a tetrahedral electron-domain geometry is sp^3 (Table 9.4). Two of the sp^3

hybrid orbitals contain nonbonding pairs of electrons, and the other two are used to make bonds with the hydrogen atoms.

Practice Exercise 1

For which of the following molecules or ions does the following description apply? "The bonding can be explained using a set of sp^2 hybrid orbitals on the central atom, with one of the hybrid orbitals holding a nonbonding pair of electrons."

- (a) CO_2 (b) H_2S (c) O_3 (d) CO_3^2
- (e) More than one of the above

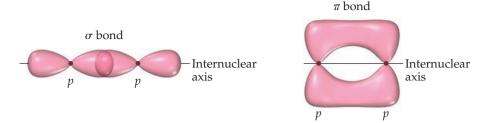

Practice Exercise 2

Predict the electron-domain geometry and hybridization of the central atom in ${\rm SO_3}^{2^-}$.

9.6 | Multiple Bonds

In the covalent bonds we have considered thus far, the electron density is concentrated along the line connecting the nuclei (the *internuclear axis*). The line joining the two nuclei passes through the middle of the overlap region, forming a type of covalent bond called a **sigma** (σ) **bond**. The overlap of two s orbitals in H₂, the overlap of an s and a p orbital in HCl, the overlap of two p orbitals in Cl₂ (all shown in Figure 9.13), and the overlap of a p orbital and an sp hybrid orbital in BeF₂ (Figure 9.16) are all σ bonds.

To describe multiple bonding, we must consider a second kind of bond, this one the result of overlap between two p orbitals oriented perpendicularly to the internuclear axis (**Figure 9.21**). The sideways overlap of p orbitals produces what is called a **pi** (π) **bond**. A π bond is one in which the overlap regions lie above and below the internuclear axis. Unlike a σ bond, in a π bond the electron density is not concentrated on the internuclear axis. Although it is not evident in Figure 9.21, the sideways orientation of p orbitals in a π bond makes for weaker overlap. As a result, π bonds are generally weaker than σ bonds.

A Figure 9.21 Comparison of σ and π bonds. Note that the two regions of overlap in the π bond, above and below the internuclear axis, constitute a *single* π bond.

In almost all cases, single bonds are σ bonds. A double bond consists of one σ bond and one π bond, and a triple bond consists of one σ bond and two π bonds:

H—H
$$C=C$$
 :N \equiv N:

One σ bond One σ bond plus one π bond plus two π bonds

▲ Figure 9.22 Trigonal-planar molecular geometry of ethylene. The double bond is made up of one $C - C \sigma$ bond and one $C - C \pi$ bond.

To see how these ideas are used, consider ethylene (C_2H_4), which has a C=C double bond. As illustrated by the ball-and-stick model of \P Figure 9.22, the three bond angles about each carbon are all approximately 120°, suggesting that each carbon atom uses sp^2 hybrid orbitals (Figure 9.17) to form σ bonds with the other carbon and with two hydrogens. Because carbon has four valence electrons, after sp^2 hybridization one electron in each carbon remains in the *unhybridized* 2p orbital. Note that this unhybridized 2p orbital is directed perpendicular to the plane that contains the three sp^2 hybrid orbitals.

Let's go through the steps of building the bonds in the ethylene molecule. Each sp^2 hybrid orbital on a carbon atom contains one electron. \blacktriangleright Figure 9.23 shows how we can first envision forming the C—C σ bond by the overlap of two sp^2 hybrid orbitals, one on each carbon atom. Two electrons are used in forming the C—C σ bond. Next, the C—H σ bonds are formed by overlap of the remaining sp^2 hybrid orbitals on the C atoms with the 1s orbitals on each H atom. We use eight more electrons to form these four C—H bonds. Thus, 10 of the 12 valence electrons in the C_2H_4 molecule are used to form five σ bonds.

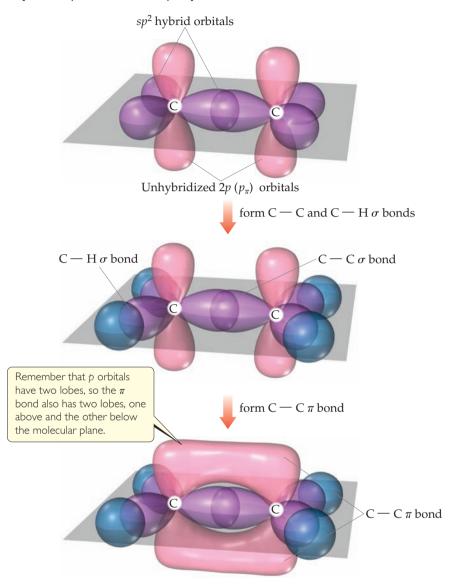

The remaining two valence electrons reside in the unhybridized 2p orbitals, one electron on each carbon. These two orbitals can overlap sideways with each other, as shown in Figure 9.23. The resultant electron density is concentrated above and below the C—C bond axis: It is a π bond (Figure 9.21). Thus, the C—C double bond in ethylene consists of one σ bond and one π bond.

We often refer to the unhybridized 2p atomic orbital of an sp^2 hybridized atom as a p_{π} ("pee-pie") orbital (because it is a p orbital that can be involved in forming a π bond). Thus, the two-electron π bond in ethylene is formed from the overlap of two p_{π} orbitals, one on each C atom and each holding one electron. Remember that the formation of the π bond involves the "sideways" overlap of the p_{π} orbitals as compared to the more direct "head on" overlap used in making the C—C and C—H σ bonds. As a result, as pointed out earlier, π bonds are generally weaker than σ bonds.

Although we cannot experimentally observe a π bond directly (all we can observe are the positions of the atoms), the structure of ethylene provides strong support for its presence. First, the C—C bond length in ethylene (1.34 Å) is much shorter than in compounds with C—C single bonds (1.54 Å), consistent with the presence of a stronger C=C double bond. Second, all six atoms in C_2H_4 lie in the same plane. The p_{π} orbitals on each C atom that make up the π bond can

Why is it important that the sp^2 hybrid orbitals of the two carbon atoms lie in the same plane?

▲ Figure 9.23 The orbital structure of ethylene, C2H4.

achieve a good overlap only when the two CH_2 fragments lie in the same plane. Because π bonds require that portions of a molecule be planar, they can introduce rigidity into molecules.

Give It Some Thought

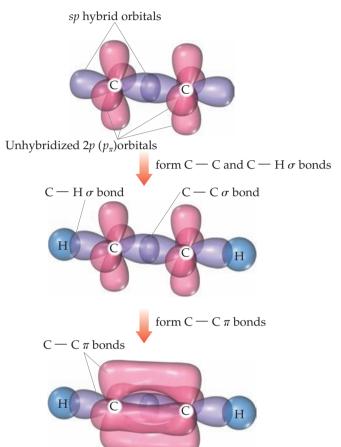

The molecule called $\emph{diazine}$ has the formula N_2H_2 and the Lewis structure

$$H-\ddot{N}=\ddot{N}-H$$

Do you expect diazine to be a linear molecule (all four atoms on the same line)? If not, do you expect the molecule to be planar (all four atoms in the same plane)?

Based on the models of bonding in ethylene and acetylene, which molecule should have the greater carbon–carbon bond energy?

▲ Figure 9.24 Formation of two π bonds in acetylene, C_2H_2 .

Triple bonds can also be explained using hybrid orbitals. Acetylene (C_2H_2) , for example, is a linear molecule containing a triple bond: $H-C\equiv C-H$. The linear geometry suggests that each carbon atom uses sp hybrid orbitals to form σ bonds with the other carbon and one hydrogen. Each carbon atom thus has two unhybridized 2p orbitals at right angles to each other and to the axis of the sp hybrid set (\P Figure 9.24). Thus, there are two p_{π} orbitals remaining on an sp-hybridized carbon atom. These p_{π} orbitals overlap to form a pair of π bonds. Thus, the triple bond in acetylene consists of one σ bond and two π bonds.

Although it is possible to make π bonds from d orbitals, the only π bonds we will consider are those formed by the overlap of p orbitals. These π bonds can form only if unhybridized p orbitals are present on the bonded atoms. Therefore, only atoms having sp or sp^2 hybridization can form π bonds. Further, double and triple bonds (and hence π bonds) are more common in molecules made up of period 2 atoms, especially C, N, and O. Larger atoms, such as S, P, and Si, form π bonds less readily.

Resonance Structures, Delocalization, and π Bonding

In the molecules we have discussed thus far in this section, the bonding electrons are *localized*. By this we mean that the σ and π electrons are associated totally with the two atoms that form the bond. In many molecules, however, we cannot adequately describe the bonding as being entirely localized. This situation arises particularly in molecules that have two or more resonance structures involving π bonds.

One molecule that cannot be described with localized π bonds is benzene (C_6H_6), which has two resonance structures: ∞ (Section 8.6)

$$\bigcirc$$
 or \bigcirc

SAMPLE EXERCISE 9.6 Describing σ and π Bonds in a Molecule

Formaldehyde has the Lewis structure

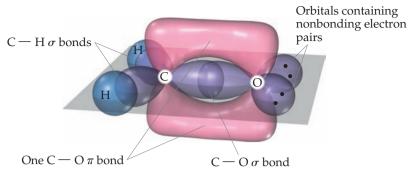

Describe how the bonds in formal dehyde are formed in terms of overlaps of hybrid and unhybridized orbitals.

SOLUTION

Analyze We are asked to describe the bonding in formaldehyde in terms of hybrid orbitals.

Plan Single bonds are σ bonds, and double bonds consist of one σ bond and one π bond. The ways in which these bonds form can be deduced from the molecular geometry, which we predict using the VSEPR model.

Solve The C atom has three electron domains around it, which suggests a trigonal-planar geometry with bond angles of about 120° . This geometry implies sp^2 hybrid orbitals on C

▲ Figure 9.25 Formation of σ and π bonds in formaldehyde, H₂CO.

(Table 9.4). These hybrids are used to make the two C—H and one C—O σ bonds to C. There remains an unhybridized 2p orbital (a p_{π} orbital) on carbon, perpendicular to the plane of the three sp^2 hybrids.

The O atom also has three electron domains around it, and so we assume it has sp^2 hybridization as well. One of these hybrid orbitals participates in the C — O σ bond, while the other two hold the two nonbonding electron pairs of the O atom. Like the C atom, therefore, the O atom has a p_{π} orbital that is perpendicular to the plane of the molecule. The two p_{π} orbitals overlap to form a C — O π bond (\blacktriangle Figure 9.25).

Practice Exercise 1

We have just arrived at a bonding description for the formaldehyde molecule. Which of the following statements about the molecule is or are true?

- (i) Two of the electrons in the molecule are used to make the π bond in the molecule.
- (ii) Six of the electrons in the molecule are used to make the σ bonds in the molecule.
- (iii) The C—O bond length in formal dehyde should be shorter than that in methanol, $\rm H_3COH.$
 - (a) Only one of the statements is true.
 - (b) Statements (i) and (ii) are true.
 - (c) Statements (i) and (iii) are true.
 - (d) Statements (ii) and (iii) are true.
 - (e) All three statements are true.

Practice Exercise 2

(a) Predict the bond angles around each carbon atom in acetonitrile:

(b) Describe the hybridization at each carbon atom, and (c) determine the number of σ and π bonds in the molecule.

Benzene has a total of 30 valence electrons. To describe the bonding in benzene using hybrid orbitals, we first choose a hybridization scheme consistent with the geometry of the molecule. Because each carbon is surrounded by three atoms at 120° angles, the appropriate hybrid set is sp^2 . Six localized C—C σ bonds and six localized C—H σ bonds are formed from the sp^2 hybrid orbitals, as shown in Figure 9.26(a). Thus, 24 of the valence electrons are used to form the σ bonds in the molecule.

Because the hybridization at each C atom is sp^2 , there is one p_{π} orbital on each C atom, each oriented perpendicular to the plane of the molecule. The situation is very much like that in ethylene except we now have six p_{π} orbitals arranged in a ring

GO FIGURE

What are the two kinds of σ bonds found in benzene?

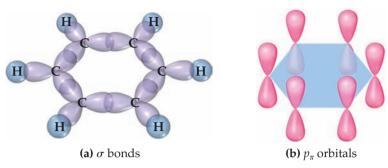

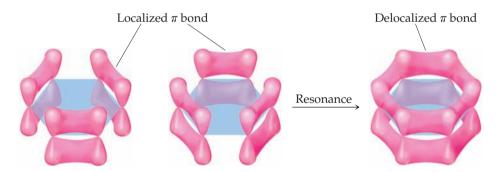

Figure 9.26 σ and π bond networks in benzene, C_6H_6 . (a) The σ bond framework. (b) The π bonds are formed from overlap of the unhybridized 2p orbitals on the six carbon atoms.

[Figure 9.26(b)]. The remaining six valence electrons occupy these six p_{π} orbitals, one per orbital.

We could envision using the p_{π} orbitals to form three localized π bonds. As shown in ▼ Figure 9.27, there are two equivalent ways to make these localized bonds, each corresponding to one resonance structure. However, a representation that reflects both resonance structures has the six π electrons "smeared out" among all six carbon atoms, as shown on the right in Figure 9.27. Notice how this smeared representation corresponds to the circle-in-a-hexagon drawing we often use to represent benzene. This model leads us to predict that all the carbon-carbon bond lengths will be identical, with a bond length between that of a C—C single bond (1.54 Å) and that of a C=C double bond (1.34 Å). This prediction is consistent with the observed carbon-carbon bond length in benzene (1.40 Å).

▲ Figure 9.27 Delocalized π bonds in benzene.

Because we cannot describe the π bonds in benzene as individual bonds between neighboring atoms, we say that benzene has a six-electron π system **delocalized** among the six carbon atoms. Delocalization of the electrons in its π bonds gives benzene a special stability. Electron delocalization in π bonds is also responsible for the color of many organic molecules. A final important point to remember about delocalized π bonds is the constraint they place on the geometry of a molecule. For optimal overlap of the p_{π} orbitals, all the atoms involved in a delocalized π bonding network should lie in the same plane. This restriction imparts a certain rigidity to the molecule that is absent in molecules containing only σ bonds (see the "Chemistry and Life" box on vision).

If you take a course in organic chemistry, you will see many examples of how electron delocalization influences the properties of organic molecules.

SAMPLE EXERCISE 9.7 Delocalized Bonding

Describe the bonding in the nitrate ion, NO_3^- . Does this ion have delocalized π bonds?

SOLUTION

Analyze Given the chemical formula for a polyatomic anion, we are asked to describe the bonding and determine whether the ion has delocalized π bonds.

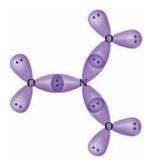

Plan Our first step is to draw Lewis structures. Multiple resonance structures involving the placement of the double bonds in different locations would suggest that the π component of the double bonds is delocalized.

Solve In Section 8.6 we saw that NO₃⁻ has three resonance structures:

$$\begin{bmatrix} : \bigcirc : \\ | \\ | \\ : \bigcirc : \end{bmatrix}^{-} \longleftrightarrow \begin{bmatrix} : \bigcirc : \\ | \\ | \\ : \bigcirc : \end{bmatrix}^{-} \longleftrightarrow In each structure, the electron-domain geometry at nitrogen is trigonal planar, which implies sp^2 hybridization of the N atom. It is helpful when considering delocalized π bonding to consider atoms with lone pairs that are bonded to the central atom to be sp^2 hybridized as well. Thus, we can envision that each of the O atoms in the anion has three sp^2 hybrid orbitals in the plane of the ion. Each of the four atoms has an unhybridized p_{π} orbital oriented perpendicular to the plane of the ion.

The NO₃⁻ ion has 24 valence electrons. We can first use the sp^2 hybrid orbitals on the four atoms to construct the three N — O σ bonds. That uses all of the sp^2 hybrids on the N atom and one sp^2 hybrid on each O atom. Each of the two remaining sp^2 hybrids on each O atom is used to hold a nonbonding pair of electrons. Thus, for any of the resonance structures, we have the following arrangement in the plane of the ion:

Notice that we have accounted for a total of 18 electrons — six in the three N — O σ bonds, and 12 as nonbonding pairs on the O atoms. The remaining six electrons will reside in the σ system of the ion.

The four p_{π} orbitals — one on each of the four atoms — are used to build the π system. For any one of the three resonance structures shown, we might imagine a single localized N—O π bond formed by the overlap of the p_{π} orbital on N and a p_{π} orbital on one of the O atoms. The remaining two O atoms have nonbonding pairs in their p_{π} orbitals. Thus, for each of the resonance structures, we have the situation shown in \blacktriangleright Figure 9.28. Because each resonance structure contributes equally to the observed structure of NO₃¯, however, we represent the π bonding as delocalized over the three N—O bonds, as shown in the figure. We see that the NO₃¯ ion has a six-electron π system delocalized among the four atoms in the ion.

General Conclusions about σ and π Bonding

On the basis of the examples we have seen, we can draw a few helpful conclusions for using hybrid orbitals to describe molecular structures:

- 1. Every pair of bonded atoms shares one or more pairs of electrons. Each bond line we draw in a Lewis structures represents two shared electrons. In every σ bond at least one pair of electrons is localized in the space between the atoms. The appropriate set of hybrid orbitals used to form the σ bonds between an atom and its neighbors is determined by the observed geometry of the molecule. The correlation between the set of hybrid orbitals and the geometry about an atom is given in Table 9.4.
- 2. Because the electrons in σ bonds are localized in the region between two bonded atoms, they do not make a significant contribution to the bonding between any other two atoms.
- 3. When atoms share more than one pair of electrons, one pair is used to form a σ bond; the additional pairs form π bonds. The centers of charge density in a π bond lie above and below the internuclear axis.
- **4.** Molecules can have π systems that extend over more than two bonded atoms. Electrons in extended π systems are said to be "delocalized." We can determine the number of electrons in the π system of a molecule using the procedures we discussed in this section.

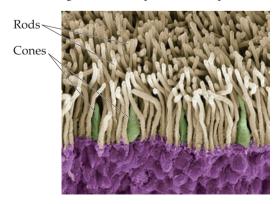

Chemistry and Life

The Chemistry of Vision

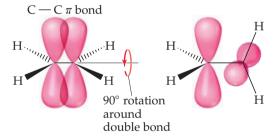

Vision begins when light is focused by the lens of the eye onto the retina, the layer of cells lining the interior of the eyeball. The retina contains *photo-receptor* cells called rods and cones (▼ Figure 9.29). The rods are sensitive to dim light and are used in night vision. The cones are sensitive to colors. The tops of the rods and cones contain a molecule called *rhodopsin*, which consists of a protein, *opsin*, bonded to a reddish purple pigment called *retinal*. Structural changes around a double bond in the retinal portion of the molecule trigger a series of chemical reactions that result in vision.

We know that a double bond between two atoms is stronger than a single bond between those same two atoms (Table 8.4). We are now in a position to appreciate another aspect of double bonds: They introduce rigidity into molecules.

Consider the C—C double bond in ethylene. Imagine rotating one —CH₂ group in ethylene relative to the other —CH₂ group, as pictured in \blacktriangleright Figure 9.30. This rotation destroys the overlap of the p_{π} orbitals, breaking the π bond, a process that requires considerable

▲ Figure 9.29 Inside the eye. A color-enhanced scanning electron micrograph of the rods and cones in the retina of the human eye.

▲ Figure 9.30 Rotation about the carbon–carbon double bond in ethylene breaks the π bond.

energy. Thus, the presence of a double bond restricts bond rotation in a molecule. In contrast, molecules can rotate almost freely around the bond axis in single (σ) bonds because this motion has no effect on the orbital overlap for a σ bond. Rotation allows molecules with single bonds to twist and fold almost as if their atoms were attached by hinges.

Our vision depends on the rigidity of double bonds in retinal. In its normal form, retinal is held rigid by its double bonds. Light entering the eye is absorbed by rhodopsin, and it is the energy of that light which is used to break the π -bond portion of the double bond shown in red in \triangleright Figure 9.31. Breaking the double bond allows rotation around the bond axis, changing the geometry of the retinal molecule. The retinal then separates from the opsin, triggering the reactions that produce a nerve impulse that the brain interprets as the sensation of vision. It takes as few as five closely spaced molecules reacting in this fashion to produce the sensation of vision. Thus, only five photons of light are necessary to stimulate the eye.

The retinal slowly reverts to its original form and reattaches to the opsin. The slowness of this process helps explain why intense bright light causes temporary blindness. The light causes all the retinal to separate from opsin, leaving no molecules to absorb light.

Related Exercises: 9.112, 9.116

▲ Figure 9.31 The rhodopsin molecule, the chemical basis of vision. When rhodopsin absorbs visible light, the π component of the double bond shown in red breaks, allowing rotation that produces a change in molecular geometry before the π bond re-forms.

Give It Some Thought

When two atoms are bonded by a triple bond, what is the hybridization of the orbitals that make up the σ -bond component of the bond?

9.7 | Molecular Orbitals

While valence-bond theory helps explain some of the relationships among Lewis structures, atomic orbitals, and molecular geometries, it does not explain all aspects of bonding. It is not successful, for example, in describing the excited states of molecules, which we must understand to explain how molecules absorb light, giving them color.

Some aspects of bonding are better explained by a more sophisticated model called **molecular orbital theory**. In Chapter 6 we saw that electrons in atoms can be described by wave functions, which we call atomic orbitals. In a similar way, molecular orbital theory describes the electrons in molecules by using specific wave functions, each of which is called a **molecular orbital (MO)**.

Molecular orbitals have many of the same characteristics as atomic orbitals. For example, an MO can hold a maximum of two electrons (with opposite spins), it has a definite energy, and we can visualize its electron-density distribution by using a contour representation, as we did with atomic orbitals. Unlike atomic orbitals, however, MOs are associated with an entire molecule, not with a single atom.

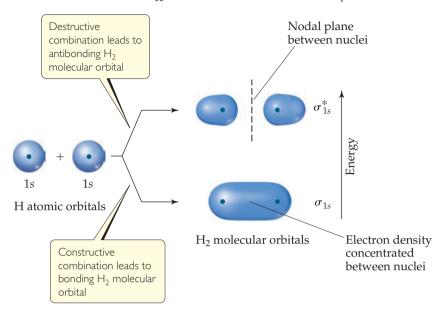

Molecular Orbitals of the Hydrogen Molecule

We begin our study of MO theory with the hydrogen molecule, H_2 . We will use the two 1s atomic orbitals (one on each H atom) to construct molecular orbitals for H_2 . Whenever two atomic orbitals overlap, two molecular orbitals form. Thus, the overlap of the 1s orbitals of two hydrogen atoms to form H_2 produces two MOs. The first MO, which is shown at the bottom right of Figure 9.32, is formed by adding the wave functions for the two 1s orbitals. We refer to this as constructive combination. The energy of the resulting MO is lower in energy than the two atomic orbitals from which it was made. It is called the **bonding molecular orbital**.

The second MO is formed by what is called *destructive combination:* combining the two atomic orbitals in a way that causes the electron density to be canceled in the central region where the two overlap. The process is discussed more fully in the "Closer Look" box later in the chapter. The energy of the resulting MO, referred to as the **anti-bonding molecular orbital**, is higher than the energy of the atomic orbitals. The anti-bonding MO of H₂ is shown at the top right in Figure 9.32.

A GO FIGURE

What is the value of the σ_{1s}^{\star} MO wave function at the nodal plane?

▲ Figure 9.32 The two molecular orbitals of H₂, one a bonding MO and one an antibonding MO.

As illustrated in Figure 9.32, in the bonding MO electron density is concentrated in the region between the two nuclei. This sausage-shaped MO results from summing the two atomic orbitals so that the atomic orbital wave functions combine in the region between the two nuclei. Because an electron in this MO is attracted to both nuclei, the electron is more stable (it has lower energy) than it is in the 1s atomic orbital of an isolated hydrogen atom. Further, because this bonding MO concentrates electron density between the nuclei, it holds the atoms together in a covalent bond.

By contrast, the antibonding MO has very little electron density between the nuclei. Instead of combining in the region between the nuclei, the atomic orbital wave functions cancel each other in this region, leaving the greatest electron density on opposite sides of the two nuclei. Thus, an antibonding MO excludes electrons from the very region in which a bond must be formed. Antibonding orbitals invariably have a *plane* in the region between the nuclei where the electron density is zero. This plane is called a **nodal plane** of the MO. (The nodal plane is shown as a dashed line in Figure 9.32 and subsequent figures.) An electron in an antibonding MO is repelled from the bonding region and is therefore less stable (it has higher energy) than it is in the 1s atomic orbital of a hydrogen atom.

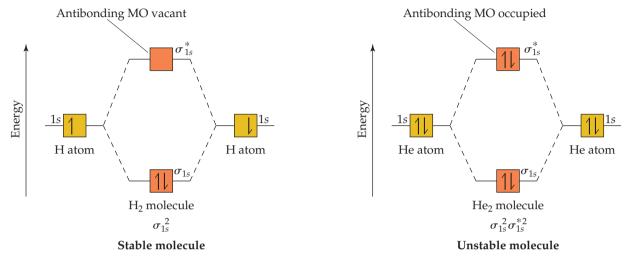

Notice from Figure 9.32 that the electron density in both the bonding MO and the antibonding MO of H_2 is centered about the internuclear axis. MOs of this type are called **sigma** (σ) **molecular orbitals** (by analogy to σ bonds). The bonding sigma MO of H_2 is labeled σ_{1s} ; the subscript indicates that the MO is formed from two 1s orbitals. The antibonding sigma MO of H_2 is labeled σ_{1s}^* (read "sigma-star-one-s"); the asterisk denotes that the MO is antibonding.

The relative energies of two 1s atomic orbitals and the molecular orbitals formed from them are represented by an **energy-level diagram** (also called a **molecular orbital diagram**). Such diagrams show the interacting atomic orbitals on the left and right and the MOs in the middle, as shown in ▶ **Figure 9.33**. Like atomic orbitals, each MO can accommodate two electrons with their spins paired (Pauli exclusion principle). **(Section 6.7)**

As the MO diagram for H_2 in Figure 9.33 shows, each H atom has one electron, so there are two electrons in H_2 . These two electrons occupy the lower-energy bonding

▲ GO FIGURE

What would happen to the energy of the σ_{1s} MO if the H atoms in H₂ were pulled apart to a distance twice as long as its normal bond length?

▲ Figure 9.33 Energy-level diagrams and electron configurations for H₂ and He₂.

 (σ_{1s}) MO, and their spins are paired. Electrons occupying a bonding molecular orbital are called *bonding electrons*. Because the σ_{1s} MO is lower in energy than the H 1s atomic orbitals, the H₂ molecule is more stable than the two separate H atoms.

By analogy with atomic electron configurations, the electron configurations for molecules can be written with superscripts to indicate electron occupancy. The electron configuration for H_2 , then, is σ_{1s}^2 .

Figure 9.33 also shows the energy-level diagram for the hypothetical He₂ molecule, which requires four electrons to fill its molecular orbitals. Because only two electrons can go in the σ_{1s} MO, the other two electrons must go in the σ_{1s}^* MO. The electron configuration of He₂ is thus $\sigma_{1s}^2\sigma_{1s}^{*2}$. The energy decrease realized in going from He atomic orbitals to the He bonding MO is offset by the energy increase realized in going from the atomic orbitals to the He antibonding MO.* Hence, He₂ is an unstable molecule. Molecular orbital theory correctly predicts that hydrogen forms diatomic molecules but helium does not.

Bond Order

In molecular orbital theory, the stability of a covalent bond is related to its **bond order**, defined as half the difference between the number of bonding electrons and the number of antibonding electrons:

Bond order = $\frac{1}{2}$ (no. of bonding electrons – no. of antibonding electrons) [9.1]

We take half the difference because we are used to thinking of bonds as pairs of electrons. A bond order of 1 represents a single bond, a bond order of 2 represents a double bond, and a bond order of 3 represents a triple bond. Because MO theory also treats molecules containing an odd number of electrons, bond orders of 1/2, 3/2, or 5/2 are possible.

Let's now consider the bond order in H_2 and He_2 , referring to Figure 9.33. H_2 has two bonding electrons and zero antibonding electrons, so it has a bond order of 1.

^{*}Antibonding MOs are slightly more energetically unfavorable than bonding MOs are energetically favorable. Thus, whenever there is an equal number of electrons in bonding and antibonding orbitals, the energy of the molecule is slightly higher than that for the separated atoms. As a result, no bond is formed.

Because He_2 has two bonding electrons and two antibonding electrons, it has a bond order of 0. A bond order of 0 means that no bond exists.

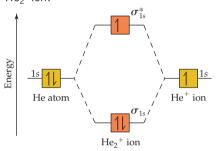

Give It Some Thought

Suppose one electron in H_2 is excited from the σ_{1s} MO to the σ_{1s}^* MO. Would you expect the H atoms to remain bonded to each other, or would the molecule fall apart?

GO FIGURE

Which electrons in this diagram contribute to the stability of the ${\rm He_2}^+$ ion?

▲ Figure 9.34 Energy-level diagram for the He₂+ ion

SAMPLE EXERCISE 9.8 Bond Order

What is the bond order of the He₂⁺ ion? Would you expect this ion to be stable relative to the separated He atom and He⁺ ion?

SOLUTION

Analyze We will determine the bond order for the $\mathrm{He_2}^+$ ion and use it to predict whether the ion is stable.

Plan To determine the bond order, we must determine the number of electrons in the molecule and how these electrons populate the available MOs. The valence electrons of He are in the 1s orbital, and the 1s orbitals combine to give an MO diagram like that for H₂ or He₂ (Figure 9.33). If the bond order is greater than 0, we expect a bond to exist, and the ion is stable.

Solve The energy-level diagram for the He_2^+ ion is shown in \triangleleft **Figure 9.34.** This ion has three electrons. Two are placed in the bonding orbital and the third in the antibonding orbital. Thus, the bond order is

Bond order =
$$\frac{1}{2}(2-1) = \frac{1}{2}$$

Because the bond order is greater than 0, we predict the He_2^+ ion to be stable relative to the separated He and He^+ . Formation of He_2^+ in the gas phase has been demonstrated in laboratory experiments.

9.8 | Period 2 Diatomic Molecules

In considering the MO description of diatomic molecules other than H_2 , we will initially restrict our discussion to *homonuclear* diatomic molecules (those composed of two identical atoms) of period 2 elements.

Period 2 atoms have valence 2s and 2p orbitals, and we need to consider how they interact to form MOs. The following rules summarize some of the guiding principles for the formation of MOs and for how they are populated by electrons:

- 1. The number of MOs formed equals the number of atomic orbitals combined.
- **2.** Atomic orbitals combine most effectively with other atomic orbitals of similar energy.
- **3.** The effectiveness with which two atomic orbitals combine is proportional to their overlap. That is, as the overlap increases, the energy of the bonding MO is lowered and the energy of the antibonding MO is raised.
- **4.** Each MO can accommodate, at most, two electrons, with their spins paired (Pauli exclusion principle). (Section 6.7)
- 5. When MOs of the same energy are populated, one electron enters each orbital (with the same spin) before spin pairing occurs (Hund's rule). (Section 6.8)

Molecular Orbitals for Li₂ and Be₂

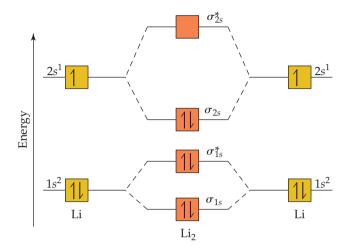

Lithium has the electron configuration $1s^22s^1$. When lithium metal is heated above its boiling point (1342 °C), Li₂ molecules are found in the vapor phase. The Lewis structure for Li₂ indicates a Li—Li single bond. We will now use MOs to describe the bonding in Li₂.

▶ Figure 9.35 shows that the Li 1s and 2s atomic orbitals have substantially different energy levels. From this, we can assume that the 1s orbital on one Li atom interacts only with the 1s orbital on the other atom (rule 2). Likewise, the 2s orbitals interact only with each other. Notice that combining four atomic orbitals produces four MOs (rule 1).

The Li 1s orbitals combine to form σ_{1s} and σ_{1s}^* bonding and antibonding MOs, as they did for H₂. The 2s orbitals interact with one another in exactly the same way, producing bonding (σ_{2s}) and antibonding (σ_{2s}^*) MOs. In general, the separation between bonding and antibonding MOs depends on the extent to which the constituent atomic orbitals overlap. Because the Li 2s orbitals extend farther from the nucleus than the 1s orbitals do, the 2s orbitals overlap more effectively. As a result, the energy difference between the σ_{2s} and σ_{2s}^* orbitals is greater than the energy difference between the σ_{1s} and σ_{1s}^* orbitals. The 1s orbitals of Li are so much lower in energy than the 2s orbitals; however, the energy of the σ_{1s}^* antibonding MO is much lower than the energy of σ_{2s} bonding MO.

▲ GO FIGURE

Which of the MOs in the diagram will have nodal planes?

▲ Figure 9.35 Energy-level diagram for the Li₂ molecule.

Each Li atom has three electrons, so six electrons must be placed in Li₂ MOs. As shown in Figure 9.35, these electrons occupy the σ_{1s} , σ_{1s}^* , and σ_{2s} MOs, each with two electrons. There are four electrons in bonding orbitals and two in antibonding orbitals, so the bond order is $\frac{1}{2}(4-2)=1$. The molecule has a single bond, in agreement with its Lewis structure.

Because both the σ_{1s} and σ_{1s}^* MOs of Li₂ are completely filled, the 1s orbitals contribute almost nothing to the bonding. The single bond in Li₂ is due essentially to the interaction of the valence 2s orbitals on the Li atoms. This example illustrates the general rule that *core electrons usually do not contribute significantly to bonding in molecules*. The rule is equivalent to using only the valence electrons when drawing Lewis structures. Thus, we need not consider further the 1s orbitals while discussing the other period 2 diatomic molecules.

The MO description of Be₂ follows readily from the energy-level diagram for Li₂. Each Be atom has four electrons ($1s^22s^2$), so we must place eight electrons in molecular orbitals. Therefore, we completely fill the σ_{1s} , σ_{1s}^* , σ_{2s} , and σ_{2s}^* MOs. With equal numbers of bonding and antibonding electrons, the bond order is zero; thus, Be₂ does not exist.

Give It Some Thought

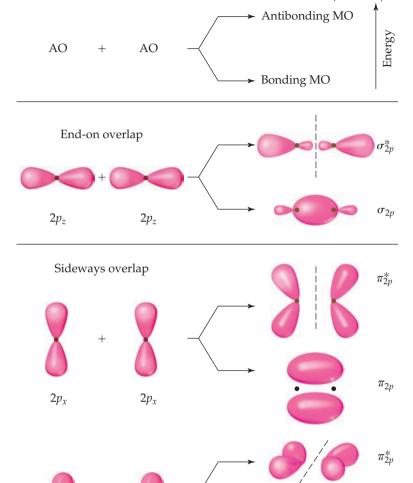

Would you expect Be₂⁺ to be a stable ion?

Molecular Orbitals from 2p Atomic Orbitals

Before we can consider the remaining period 2 diatomic molecules, we must look at the MOs that result from combining 2p atomic orbitals. The interactions between p orbitals are shown in Figure 9.36, where we have arbitrarily chosen the internuclear axis to be the z-axis. The $2p_z$ orbitals face each other head to head. Just as with s orbitals, we can combine $2p_z$ orbitals in two ways. One combination concentrates electron density between the nuclei and is, therefore, a bonding molecular orbital. The other combination excludes electron density from the bonding region and so is an antibonding

▲ GO FIGURE

In which MO is the overlap of atomic orbitals greater, a σ_{2p} or a π_{2p} ?

▲ Figure 9.36 Contour representations of the molecular orbitals formed by 2p orbitals.

molecular orbital. In both MOs, the electron density lies along the internuclear axis, so they are σ molecular orbitals: σ_{2p} and σ_{2p}^* .

 π_{2p}

The other 2p orbitals overlap sideways and thus concentrate electron density above and below the internuclear axis. MOs of this type are called **pi** (π) molecular orbitals by analogy to π bonds. We get one π bonding MO by combining the $2p_x$ atomic orbitals and another from the $2p_y$ atomic orbitals. These two π_{2p} molecular orbitals have the same energy; in other words, they are degenerate. Likewise, we get two degenerate π_{2p}^* antibonding MOs that are perpendicular to each other like the 2p orbitals from which they were made. These π_{2p}^* orbitals have four lobes, pointing away from the two nuclei, as shown in Figure 9.36.

The $2p_z$ orbitals on two atoms point directly at each other. Hence, the overlap of two $2p_z$ orbitals is greater than that of two $2p_x$ or $2p_y$ orbitals. From rule 3 we therefore expect the σ_{2p} MO to be lower in energy (more stable) than the π_{2p} MOs. Similarly, the σ_{2p}^* MO should be higher in energy (less stable) than the π_{2p}^* MOs.

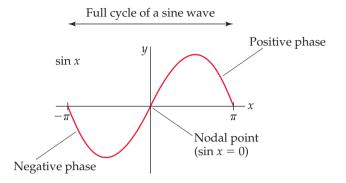

A Closer Look

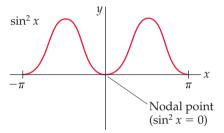

Phases in Atomic and Molecular Orbitals

Our discussion of atomic orbitals in Chapter 6 and molecular orbitals in this chapter highlights some of the most important applications of quantum mechanics in chemistry. In the quantum mechanical treatment of electrons in atoms and molecules, we are mainly interested in determining two characteristics of the electrons—their energies and their distribution in space. Recall that solving Schrödinger's wave equation yields the electron's energy, E, and wave function, ψ , but that ψ does not have a direct physical meaning. (Section 6.5) The contour representations of atomic and molecular orbitals we have presented thus far are based on ψ^2 (the *probability density*), which gives the probability of finding the electron at a given point in space.

Because probability densities are squares of functions, their values must be nonnegative (zero or positive) at all points in space. However, the functions themselves can have negative values. The situation is like that of the sine function plotted in \blacktriangleright Figure 9.37. In the top graph, the sine function is negative for x between 0 and $-\pi$ and positive for x between 0 and $+\pi$. We say that the *phase* of the sine function is negative between 0 and $-\pi$ and positive between 0 and $+\pi$. If we square the sine function (bottom graph), we get two peaks that are symmetrical about the origin. Both peaks are positive because squaring a negative number produces a positive number. In other words, we lose the phase information of the function upon squaring it.

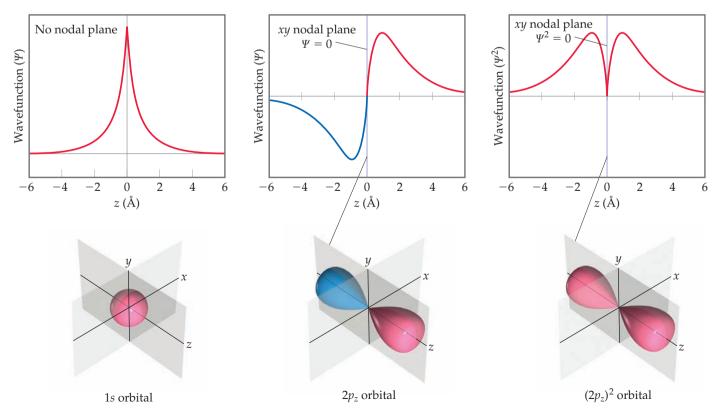

Like the sine function, the more complicated wave functions for atomic orbitals can also have phases. Consider, for example, the representations of the 1s orbital in ▼ Figure 9.38. Note that here we plot this orbital a bit differently from what is shown in Section 6.6. The origin is the point where the nucleus resides, and the wave function for the 1s orbital extends from the origin out into space. The plot shows

▲ Figure 9.37 Graphs for a sine function and the same function squared.

the value of ψ for a slice taken along the *z*-axis. Below the plot is a contour representation of the 1*s* orbital. Notice that the value of the 1*s* wave function is always a positive number (we show positive values in red in Figure 9.38). Thus, it has only one phase. Notice also that the wave function approaches zero only at a long distance from the nucleus. It therefore has no nodes, as we saw in Figure 6.22.

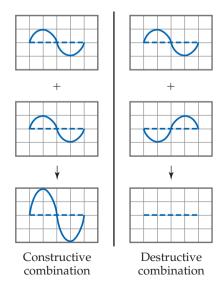

▲ Figure 9.38 Phases in wave functions of *s* and *p* atomic orbitals. Red shading means a positive value for the wave function and blue shading means a negative value.

In the graph for the $2p_z$ orbital in Figure 9.38, the wave function changes sign when it passes through z=0. Notice that the two halves of the wave have the same shape except that one has positive (red) values and the other negative (blue) values. Analogously to the sine function, the wave function changes phase when it passes through the origin. Mathematically the $2p_z$ wave function is equal to zero whenever z=0. This corresponds to any point on the xy plane, so we say that the xy plane is a nodal plane of the $2p_z$ orbital. The wave function for a p orbital is much like a sine function because it has two equal parts that have opposite phases. Figure 9.38 gives a typical representation used by chemists of the wave function for a p_z orbital.* The red and blue lobes indicate the different phases of the orbital. (Note: The colors do not represent charge, as they did in the plots in Figures 9.10 and 9.11.) As with the sine function, the origin is a node.

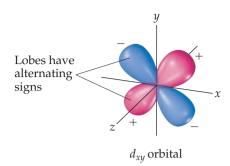

The third graph in Figure 9.38 shows that when we square the wave function of the $2p_z$ orbital, we get two peaks that are symmetrical about the origin. Both peaks are positive because squaring a negative number produces a positive number. Thus, we lose the phase information of the function upon squaring it just as we did for the sine function. When we square the wave function for the p_z orbital, we get the probability density for the orbital, which is given as a contour representation in Figure 9.38. This is what we saw in the earlier presentation of p orbitals. ∞ (Section 6.6) For this squared wave function, both lobes have the same phase and therefore the same sign. We use this representation throughout most of this book because it has a simple physical interpretation: The square of the wave function at any point in space represents the electron density at that point.

The lobes of the wave functions for the d orbitals also have different phases. For example, the wave function for a d_{xy} orbital has four lobes, with the phase of each lobe opposite the phase of its nearest neighbors (\blacktriangleright Figure 9.39). The wave functions for the other d orbitals likewise have lobes in which the phase in one lobe is opposite that in an adjacent lobe.

Why do we need to consider the complexity introduced by considering the phase of the wave function? While it is true that the phase is not necessary to visualize the shape of an atomic orbital in an isolated atom, it does become important when we consider overlap of orbitals in molecular orbital theory. Let's use the sine function as an example again. If you add two sine functions having the same phase, they add *constructively*, resulting in increased amplitude:

^{*}The mathematical development of this three-dimensional function (and its square) is beyond the scope of this book, and, as is typically done by chemists, we have used lobes that are the same shape as in Figure 6.23.

▲ Figure 9.39 Phases in d orbitals.

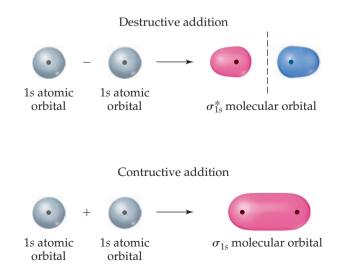

but if you add two sine functions having opposite phases, they add *destructively* and cancel each other.

The idea of constructive and destructive interactions of wave functions is key to understanding the origin of bonding and antibonding molecular orbitals. For example, the wave function of the σ_{1s} MO of H₂ is generated by adding the wave function for the 1s orbital on one atom to the wave function for the 1s orbital on the other atom, with both orbitals having the same phase. The atomic wave functions overlap constructively in this case to increase the electron density between the two atoms (∇ Figure 9.40). The wave function of the σ_{1s}^* MO of H₂ is generated by subtracting the wave function for a 1s orbital on one atom from the wave function for a 1s orbital on the other atom. The result is that the atomic orbital wave functions overlap destructively to create a region of zero electron density between the two atoms-a node. Notice the similarity between this figure and Figure 9.32. In Figure 9.40, we use red and blue shading to denote positive and negative phases in the H atomic orbitals. However, chemists may alternatively draw contour representations in different colors, or with one phase shaded and one unshaded, to denote the two phases.

When we square the wave function of the σ_{1s}^* MO, we get the electron density representation which we saw earlier, in Figure 9.32. Notice once again that we lose the phase information when we look at the electron density.

The wave functions of atomic and molecular orbitals are used by chemists to understand many aspects of chemical bonding, spectroscopy, and reactivity. If you take a course in organic chemistry, you will probably see orbitals drawn to show the phases as in this box.

Electron Configurations for B2 through Ne2

We can combine our analyses of MOs formed from s orbitals (Figure 9.32) and from p orbitals (Figure 9.36) to construct an energy-level diagram (∇ Figure 9.41) for homonuclear diatomic molecules of the elements boron through neon, all of which have valence 2s and 2p atomic orbitals. The following features of the diagram are notable:

- 1. The 2s atomic orbitals are substantially lower in energy than the 2p atomic orbitals. ∞ (Section 6.7) Consequently, both MOs formed from the 2s orbitals are lower in energy than the lowest-energy MO derived from the 2p atomic orbitals.
- **2.** The overlap of the two $2p_z$ orbitals is greater than that of the two $2p_x$ or $2p_y$ orbitals. As a result, the bonding σ_{2p} MO is lower in energy than the π_{2p} MOs, and the antibonding σ_{2p}^* MO is higher in energy than the π_{2p}^* MOs.
- 3. Both the π_{2p} and π_{2p}^* MOs are *doubly degenerate*; that is, there are two degenerate MOs of each type.

Before we can add electrons to Figure 9.41, we must consider one more effect. We have constructed the diagram assuming no interaction between the 2s orbital on one atom and the 2p orbitals on the other. In fact, such interactions can and do take place. **Figure 9.42** shows the overlap of a 2s orbital on one of the atoms with a 2p orbital on the other. These interactions increase the energy difference between the σ_{2s} and σ_{2p} MOs, with the σ_{2s} energy decreasing and the σ_{2p} energy increasing (Figure 9.42). These 2s-2p interactions can be strong enough that the energetic ordering of the MOs can be altered: For B_2 , C_2 , and N_2 , the σ_{2p} MO is above the π_{2p} MOs in energy. For O_2 , F_2 , and N_2 , the σ_{2p} MO is below the π_{2p} MOs.

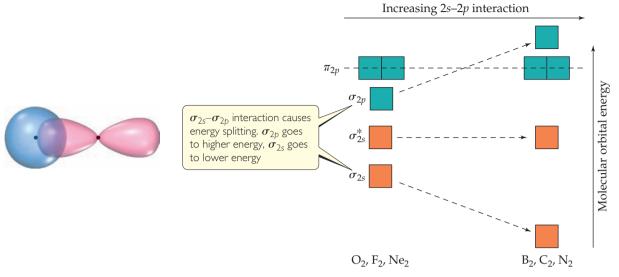

Given the energy ordering of the molecular orbitals, it is a simple matter to determine the electron configurations for the diatomic molecules B_2 through Ne_2 . For example, a boron atom has three valence electrons. (Remember that we are ignoring the core 1s electrons.) Thus, for B_2 we must place six electrons in MOs. Four of them fill the σ_{2s} and σ_{2s}^* MOs, leading to no net bonding. The fifth electron goes in one π_{2p} MO, and the

▲ Figure 9.41 Energy-level diagram for MOs of period 2 homonuclear diatomic molecules. The diagram assumes no interaction between the 2s atomic orbital on one atom and the 2p atomic orbitals on the other atom, and experiment shows that it fits only for O₂, F₂, and Ne₂.

▲ Figure 9.42 The effect of interactions between 2s and 2p atomic orbitals.

sixth goes in the other π_{2p} MO, with the two electrons having the same spin. Therefore, B₂ has a bond order of 1.

Each time we move one element to the right in period 2, two more electrons must be placed in the diagram of Figure 9.41. For example, on moving to C2, we have two more electrons than in B₂, and these electrons are placed in the π_{2p} MOs, completely filling them. The electron configurations and bond orders for B2 through Ne2 are given in **▼** Figure 9.43.

Electron Configurations and Molecular Properties

The way a substance behaves in a magnetic field can in some cases provide insight into the arrangements of its electrons. Molecules with one or more unpaired electrons are attracted to a magnetic field. The more unpaired electrons in a species, the stronger the attractive force. This type of magnetic behavior is called **paramagnetism**.

Substances with no unpaired electrons are weakly repelled by a magnetic field. This property is called **diamagnetism**. The distinction between paramagnetism and diamagnetism is nicely illustrated in an older method for measuring magnetic properties (**V Figure 9.44**). It involves weighing the substance in the presence and absence of a magnetic field. A paramagnetic substance appears to weigh more in the magnetic field; a diamagnetic substance appears to weigh less. The magnetic behaviors observed for the period 2 diatomic molecules agree with the electron configurations shown in Figure 9.43.

Give It Some Thought

Figure 9.43 indicates that C_2 is diamagnetic. Would that be expected if the σ_{2p} MO were lower in energy than the π_{2p} MOs?

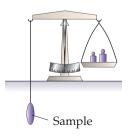

Electron configurations in molecules can also be related to bond distances and bond enthalpies. ∞ (Section 8.8) As bond order increases, bond distances decrease and bond enthalpies increase. N_2 , for example, whose bond order is 3, has a short bond distance and a large bond enthalpy. The N_2 molecule does not react readily with other substances to form nitrogen compounds. The high bond order of the molecule helps explain its exceptional stability. We should also note, however, that molecules with the same bond orders do *not* have the same bond distances and bond enthalpies. Bond order is only one factor influencing these properties. Other factors include nuclear charge and extent of orbital overlap.

Bonding in O_2 provides an interesting test case for molecular orbital theory. The Lewis structure for this molecule shows a double bond and complete pairing of electrons:

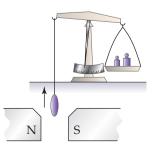

The short O — O bond distance (1.21 Å) and relatively high bond enthalpy (495 kJ/mol) are in agreement with the presence of a double bond. However, Figure 9.43 tells us that the molecule contains two unpaired electrons and should therefore be paramagnetic, a detail not discernible in the Lewis structure. The paramagnetism of O_2 is demonstrated in Figure 9.45, which confirms the prediction from MO theory. The MO description also correctly predicts a bond order of 2 as did the Lewis structure.

Going from O_2 to F_2 , we add two electrons, completely filling the π_{2p}^* MOs. Thus, F_2 is expected to be diamagnetic and have an F—F single bond, in accord with its Lewis structure. Finally, the addition of two more electrons to make Ne_2 fills all the bonding and antibonding MOs. Therefore, the bond order of Ne_2 is zero, and the molecule is not expected to exist.

SAMPLE EXERCISE 9.9

Molecular Orbitals of a Period 2 Diatomic Ion

For the O_2^+ ion predict (a) number of unpaired electrons, (b) bond order, (c) bond enthalpy and bond length.

SOLUTION

Analyze Our task is to predict several properties of the cation O_2^+ .

Plan We will use the MO description of $\mathrm{O_2}^+$ to determine the desired properties. We must first determine the number of electrons in $\mathrm{O_2}^+$ and then draw its MO energy diagram. The unpaired electrons are those without a partner of opposite spin. The bond order is one-half the difference between the number of bonding and antibonding electrons. After calculating the bond order, we can use Figure 9.43 to estimate the bond enthalpy and bond length.

Solve

- (a) The O_2^+ ion has 11 valence electrons, one fewer than O_2 . The electron removed from O_2 to form O_2^+ is one of the two unpaired π_{2p}^* electrons (see Figure 9.43). Therefore, O_2^+ has one unpaired electron.
- (b) The molecule has eight bonding electrons (the same as O₂) and three antibonding electrons (one fewer than O₂). Thus, its bond order is

$$\frac{1}{2}(8-3)=2\frac{1}{2}$$

(c) The bond order of ${\rm O_2}^+$ is between that for ${\rm O_2}$ (bond order 2) and ${\rm N_2}$ (bond order 3). Thus, the bond enthalpy and bond length should be about midway between those for ${\rm O_2}$ and ${\rm N_2}$, approximately 700 kJ/mol and 1.15 Å. (The experimentally measured values are 625 kJ/mol and 1.123 Å.)

Practice Exercise 1

Place the following molecular ions in order from smallest to largest bond order: ${\rm C_2}^{2+}$, ${\rm N_2}^-$, ${\rm O_2}^-$, and ${\rm F_2}^-$.

(a)
$$C_2^{2+} < N_2^- < O_2^- < F_2^-$$
 (b) $F_2^- < O_2^- < N_2^- < C_2^{2+}$ (c) $O_2^- < C_2^{2+} < F_2^- < N_2^-$ (d) $C_2^{2+} < F_2^- < O_2^- < N_2^-$ (e) $F_2^- < C_2^{2+} < O_2^- < N_2^-$

Practice Exercise 2

Predict the magnetic properties and bond orders of (a) the peroxide ion, O_2^{2-} ; (b) the acetylide ion, C_2^{2-} .

Heteronuclear Diatomic Molecules

The principles we have used in developing an MO description of homonuclear diatomic molecules can be extended to *heteronuclear* diatomic molecules—those in which the two atoms in the molecule are not the same—and we conclude this section with a fascinating heteronuclear diatomic molecule—nitric oxide, NO.

The NO molecule controls several important human physiological functions. Our bodies use it, for example, to relax muscles, kill foreign cells, and reinforce memory. The 1998 Nobel Prize in Physiology or Medicine was awarded to three scientists for their research that uncovered the importance of NO as a "signaling" molecule in the cardio-vascular system. NO also functions as a neurotransmitter and is implicated in many other

biological pathways. That NO plays such an important role in human metabolism was unsuspected before 1987 because NO has an odd number of electrons and is highly reactive. The molecule has 11 valence electrons, and two possible Lewis structures can be drawn. The Lewis structure with the lower formal charges places the odd electron on the N atom:

$$\dot{N} = \ddot{O} \longleftrightarrow \ddot{N} = \ddot{O}$$

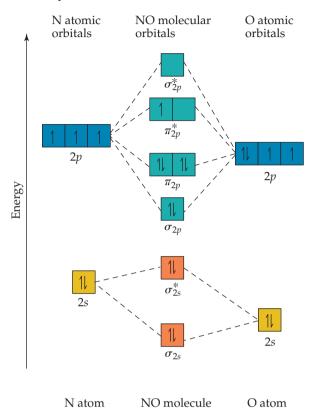

Both structures indicate the presence of a double bond, but when compared with the molecules in Figure 9.43, the experimental bond length of NO (1.15 Å) suggests a bond order greater than 2. How do we treat NO using the MO model?

If the atoms in a heteronuclear diatomic molecule do not differ too greatly in electronegativities, their MOs resemble those in homonuclear diatomics, with one important modification: The energy of the atomic orbitals of the more electronegative atom is lower than that of the atomic orbitals of the less electronegative element. In \triangleright Figure 9.46, you see that the 2s and 2p atomic orbitals of oxygen are slightly lower than those of nitrogen because oxygen is more electronegative than nitrogen. The MO energy-level diagram for NO is much like that of a homonuclear diatomic molecule—because the 2s and 2p orbitals on the two atoms interact, the same types of MOs are produced.

There is one other important difference in the MOs of heteronuclear molecules. The MOs are still a mix of atomic orbitals from both atoms, but in general an MO in a heteronuclear diatomic molecule has a greater contribution from the atomic orbital to which it is closer in energy. In the case of NO, for example, the σ_{2s} bonding MO is closer in energy to the O 2s atomic orbital than to the N 2s atomic orbital. As a result, the σ_{2s} MO has a slightly greater contribution from O than from N—the orbital is no longer an equal mixture of the two atoms, as was the case for the homonuclear diatomic molecules. Similarly, the σ_{2s}^* antibonding MO is weighted more heavily toward the N atom because that MO is closest in energy to the N 2s atomic orbital.

How many valence-shell electrons are there in NO?

▲ Figure 9.46 The energy-level diagram for atomic and molecular orbitals in NO.

Chemistry Put to Work

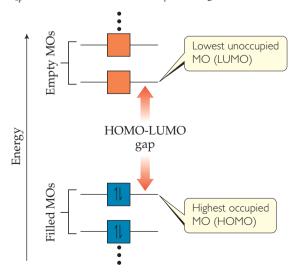

Orbitals and Energy

Asked to identify the major technological challenge for the twenty-first century, you might say "energy," reasoning that development of sustainable energy sources is crucial to meet the needs of future generations of people on our planet. One of the most remarkable sources of clean energy is the Sun, which receives plenty of energy daily to power the world for millions of years. Our challenge is to capture enough of this energy in a form that allows us to use it as needed. *Photovoltaic solar cells* convert the light from the Sun into usable electricity, and the development of more efficient solar cells is one way to address Earth's future energy needs.

How does solar energy conversion work? Fundamentally, we need to be able to use photons from the Sun, especially from the visible portion of the spectrum, to excite electrons in molecules and materials to different energy levels. The brilliant colors around you—those of your clothes, the photographs in this book, the foods you eat—are due to the selective absorption of visible light by chemicals. It is helpful to think of this process in the context of molecular orbital theory: Light excites an electron from a filled molecular orbital to an empty one at higher energy. Because MOs have definite energies, only light of the proper wavelengths can excite electrons.

In discussing light absorption by molecules, we can focus on the two MOs shown in **Figure 9.47**. The *highest occupied molecular orbital* (HOMO) is the MO of highest energy that has electrons in it. The

lowest unoccupied molecular orbital (LUMO) is the MO of lowest energy that does not have electrons in it. In N₂, for example, the HOMO is the σ_{2p} MO and the LUMO is the π_{2p}^* MO (Figure 9.43).

▲ Figure 9.47 Definitions of the highest occupied and lowest unoccupied molecular orbitals. The energy difference between these is the HOMO-LUMO gap.

The energy difference between the HOMO and the LUMO—known as the HOMO–LUMO gap—is related to the minimum energy needed to excite an electron in the molecule. Colorless or white substances usually have such a large HOMO–LUMO gap that visible light is not energetic enough to excite an electron to the higher level. The minimum energy needed to excite an electron from the HOMO to the LUMO in $\rm N_2$ corresponds to light with a wavelength of less than 200 nm, which is far into the ultraviolet part of the spectrum. ∞ (Figure 6.4) As a result, $\rm N_2$ cannot absorb visible light and is therefore colorless.

The magnitude of the energy gap between filled and empty electronic states is critical for solar energy conversion. Ideally, we want a substance that absorbs as many solar photons as possible and then converts the energy of those photons into a useful form of energy. Titanium dioxide is a readily available material that can be reasonably

efficient at converting light directly into electricity. However, TiO_2 is white and absorbs only a small amount of the Sun's radiant energy. Scientists are working to make solar cells in which TiO_2 is mixed with highly colored molecules, whose HOMO–LUMO gaps correspond to visible and near-infrared light—molecules that can absorb more of the solar spectrum. If the HOMO of these molecules is higher in energy than the HOMO of TiO_2 , the excited electrons will flow from the molecules into the TiO_2 , thereby generating electricity when the device is illuminated with light and connected to an external circuit.

Efficient solar energy conversion promises to be one of the most interesting and important areas of both scientific and technological development in our future. Many of you may ultimately end up working in fields that have an impact on the world's energy portfolio.

Related Exercises: 9.109, 9.120, Design an Experiment

We complete the MO diagram for NO by filling the MOs in Figure 9.46 with the 11 valence electrons. Eight bonding and three antibonding electrons give a bond order of $\frac{1}{2}(8-3)=2\frac{1}{2}$, which agrees better with experiment than the Lewis structures do. The unpaired electron resides in one of the π_{2p}^* MOs, which have a greater contribution from the N atom. (We could have placed this electron in either the left or right π_{2p}^* MO.) Thus, the Lewis structure that places the unpaired electron on nitrogen (the one preferred on the basis of formal charge) is the more accurate description of the true electron distribution in the molecule.

SAMPLE INTEGRATIVE EXERCIS

INTEGRATIVE EXERCISE Putting Concepts Together

Elemental sulfur is a yellow solid that consists of S_8 molecules. The structure of the S_8 molecule is a puckered, eight-membered ring (see Figure 7.27). Heating elemental sulfur to high temperatures produces gaseous S_2 molecules:

$$S_8(s) \longrightarrow 4 S_2(g)$$

(a) The electron configuration of which period 2 element is most similar to that of sulfur? (b) Use the VSEPR model to predict the S - S - S bond angles in S_8 and the hybridization at S in S_8 . (c) Use MO theory to predict the sulfursulfur bond order in S_2 . Do you expect this molecule to be diamagnetic or paramagnetic? (d) Use average bond enthalpies (Table 8.4) to estimate the enthalpy change for this reaction. Is the reaction exothermic or endothermic?

SOLUTION

- (a) Sulfur is a group 6A element with an $[Ne]3s^23p^4$ electron configuration. It is expected to be most similar electronically to oxygen (electron configuration, $[He]2s^22p^4$), which is immediately above it in the periodic table.
- **(b)** The Lewis structure of S_8 is

There is a single bond between each pair of S atoms and two nonbonding electron pairs on each S atom. Thus, we see four electron domains around each S atom and expect a tetrahedral electron-domain geometry corresponding to sp^3 hybridization. Because of the nonbonding pairs, we expect the S — S — S angles to be somewhat less than 109.5° , the tetrahedral angle. Experimentally, the S — S — S angle in S₈ is 108° , in good agreement with this prediction. Interestingly, if S₈ were a planar ring, it

- would have S S S angles of 135°. Instead, the S_8 ring puckers to accommodate the smaller angles dictated by sp^3 hybridization.
- (c) The MOs of S₂ are analogous to those of O₂, although the MOs for S₂ are constructed from the 3s and 3p atomic orbitals of sulfur. Further, S₂ has the same number of valence electrons as O₂. Thus, by analogy with O₂, we expect S₂ to have a bond order of 2 (a double bond) and to be paramagnetic with two unpaired electrons in the π^{*}_{3p} molecular orbitals of S₂.
- (d) We are considering the reaction in which an S₈ molecule falls apart into four S₂ molecules. From parts (b) and (c), we see that S₈ has S S single bonds and S₂ has S = S double bonds. During the reaction, therefore, we are breaking eight S S single bonds and forming four S = S double bonds. We can estimate the enthalpy of the reaction by using Equation 8.12 and the average bond enthalpies in Table 8.4:

$$\Delta H_{\text{rxn}} = 8D(S - S) - 4D(S - S) = 8(266 \text{ kJ}) - 4(418 \text{ kJ}) = +456 \text{ kJ}$$

Recall that D(X-Y) represents the X-Y bond enthalpy. Because $\Delta H_{\rm rxn} > 0$, the reaction is endothermic. (Section 5.4) The very positive value of $\Delta H_{\rm rxn}$ suggests that high temperatures are required to cause the reaction to occur.

Chapter Summary and Key Terms

MOLECULAR SHAPES (INTRODUCTION AND SECTION 9.1)

The three-dimensional shapes and sizes of molecules are determined by their **bond angles** and bond lengths. Molecules with a central atom A surrounded by n atoms B, denoted AB_n , adopt a number of different

geometric shapes, depending on the value of n and on the particular atoms involved. In the overwhelming majority of cases, these geometries are related to five basic shapes (linear, trigonal pyramidal, tetrahedral, trigonal bipyramidal, and octahedral).

THE VSEPR MODEL (SECTION 9.2) The **valence-shell electron-pair repulsion (VSEPR) model** rationalizes molecular geometries based on the repulsions between **electron domains**, which are regions about a central atom in which electrons are likely to be found. **Bonding pairs** of electrons, which are those involved in making bonds, and **nonbonding pairs** of electrons, also called **lone pairs**, both create electron domains around an atom. According to the VSEPR model, electron domains orient themselves to minimize electrostatic repulsions; that is, they remain as far apart as possible.

Electron domains from nonbonding pairs exert slightly greater repulsions than those from bonding pairs, which leads to certain preferred positions for nonbonding pairs and to the departure of bond angles from idealized values. Electron domains from multiple bonds exert slightly greater repulsions than those from single bonds. The arrangement of electron domains around a central atom is called the **electron-domain geometry**; the arrangement of atoms is called the **molecular geometry**.

MOLECULAR POLARITY (SECTION 9.3) The dipole moment of a polyatomic molecule depends on the vector sum of the dipole moments associated with the individual bonds, called the **bond dipoles**. Certain molecular shapes, such as linear AB_2 and trigonal planar AB_3 , lead to cancellation of the bond dipoles, producing a nonpolar molecule, which is one whose overall dipole moment is zero. In other shapes, such as bent AB_2 and trigonal pyramidal AB_3 , the bond dipoles do not cancel and the molecule will be polar (that is, it will have a nonzero dipole moment).

COVALENT BONDING AND VALENCE-BOND THEORY (SECTION 9.4)

Valence-bond theory is an extension of Lewis's notion of electron-pair bonds. In valence-bond theory, covalent bonds are formed when atomic orbitals on neighboring atoms overlap one another. The overlap region is one of greater stability for the two electrons because of their simultaneous attraction to two nuclei. The greater the overlap between two orbitals, the stronger the bond that is formed.

HYBRID ORBITALS (SECTION 9.5) To extend the ideas of valence-bond theory to polyatomic molecules, we must envision mixing s and p orbitals to form **hybrid orbitals**. The process of **hybridization** leads to hybrid atomic orbitals that have a large lobe directed to overlap with orbitals on another atom to make a bond. Hybrid orbitals can also accommodate nonbonding pairs. A particular mode of hybridization can be associated with each of three common electron-domain geometries (linear = sp; trigonal planar = sp^2 ; tetrahedral = sp^3). The bonding in **hypervalent** molecules—those with more than an octet of electrons—are not as readily discussed in terms of hybrid orbitals.

MULTIPLE BONDS (SECTION 9.6) Covalent bonds in which the electron density lies along the line connecting the atoms (the internuclear axis) are called **sigma** (σ) **bonds**. Bonds can also be formed from the sideways overlap of p orbitals. Such a bond is called a **pi** (π) **bond**. A double bond, such as that in C_2H_4 , consists of one σ bond and one π bond; each carbon atom has an unhybridized p_{π} **orbital**, and these are the orbitals that overlap to form π bonds. A triple bond, such as that in C_2H_2 , consists of one σ and two π bonds. The formation of a π bond requires that molecules adopt a specific orientation; the two CH_2 groups in C_2H_4 , for example, must lie in the same plane. As a result, the presence of π bonds introduces rigidity into molecules. In molecules that have multiple bonds

and more than one resonance structure, such as C_6H_6 , the π bonds are **delocalized**; that is, the π bonds are spread among several atoms.

MOLECULAR ORBITALS (SECTION 9.7) Molecular orbital theory is another model used to describe the bonding in molecules. In this model the electrons exist in allowed energy states called molecular orbitals (MOs). An MO can extend over all the atoms of a molecule. Like an atomic orbital, a molecular orbital has a definite energy and can hold two electrons of opposite spin. We can build molecular orbitals by combining atomic orbitals on different atomic centers. In the simplest case, the combination of two atomic orbitals leads to the formation of two MOs, one at lower energy and one at higher energy relative to the energy of the atomic orbitals. The lower-energy MO concentrates charge density in the region between the nuclei and is called a bonding molecular orbital. The higher-energy MO excludes electrons from the region between the nuclei and is called an antibonding molecular orbital. Antibonding MOs exclude electron density from the region between the nuclei and have a **nodal plane**—a place at which the electron density is zero—between the nuclei. Occupation of bonding MOs favors bond formation, whereas occupation of antibonding MOs is unfavorable. The bonding and antibonding MOs formed by the combination of s orbitals are sigma (σ) molecular orbitals; they lie on the internuclear axis.

The combination of atomic orbitals and the relative energies of the molecular orbitals are shown by an **energy-level** (or **molecular orbital**) **diagram**. When the appropriate number of electrons is put into the MOs, we can calculate the **bond order** of a bond, which is half the difference between the number of electrons in bonding MOs and the number of electrons in antibonding MOs. A bond order of 1 corresponds to a single bond, and so forth. Bond orders can be fractional numbers.

MOLECULAR ORBITALS OF PERIOD 2 DIATOMIC MOLECULES (SECTION 9.8) Electrons in core orbitals do not contribute to the bonding between atoms, so a molecular orbital description usually needs to consider only electrons in the outermost electron subshells. To describe the MOs of period 2 homonuclear diatomic molecules, we need to consider the MOs that can form by the combination of porbitals. The p orbitals that point directly at one another can form σ bonding and σ^* antibonding MOs. The p orbitals that are oriented perpendicular to the internuclear axis combine to form pi (π) molecular orbitals. In diatomic molecules the π molecular orbitals occur as a pair of degenerate (same energy) bonding MOs and a pair of degenerate antibonding MOs. The σ_{2p} bonding MO is expected to be lower in energy than the π_{2p} bonding MOs because of larger orbital overlap of the p orbitals directed along the internuclear axis. However, this ordering is reversed in B2, C2, and N2 because of interaction between the 2s and 2p atomic orbitals of different atoms.

The molecular orbital description of period 2 diatomic molecules leads to bond orders in accord with the Lewis structures of these molecules. Further, the model predicts correctly that $\rm O_2$ should exhibit paramagnetism, which leads to attraction of a molecule into a magnetic field due to the influence of unpaired electrons. Molecules in which all the electrons are paired exhibit diamagnetism, which leads to weak repulsion from a magnetic field. The molecular orbitals of heteronuclear diatomic molecules are often closely related to those of homonuclear diatomic molecules.

Learning Outcomes After studying this chapter, you should be able to:

- Predict the three-dimensional shapes of molecules using the VSEPR model. (Section 9.2)
- Determine whether a molecule is polar or nonpolar based on its geometry and the individual bond dipole moments. (Section 9.3)
- Explain the role of orbital overlap in the formation of covalent bonds. (Section 9.4)
- Determine the hybridization atoms in molecules based on observed molecular structures. (Section 9.5)
- Sketch how orbitals overlap to form sigma (σ) and pi (π) bonds. (Section 9.6)
- Explain the existence of delocalized π bonds in molecules such as benzene. (Section 9.6)

- Count the number of electrons in a delocalized π system. (Section 9.6)
- Explain the concept of bonding and antibonding molecular orbitals and draw examples of σ and π MOs. (Section 9.7)
- Draw molecular orbital energy-level diagrams and place electrons into them to obtain the bond orders and electron configurations of diatomic molecules using molecular orbital theory. (Sections 9.7 and 9.8)
- Correlate bond order, bond strength (bond enthalpy), bond length, and magnetic properties with molecular orbital descriptions of molecules. (Section 9.8)

Key Equations

• Bond order = $\frac{1}{2}$ (no. of bonding electrons – no. of antibonding electrons) [9.1]

Exercises

Visualizing Concepts

9.1 A certain AB₄ molecule has a "seesaw" shape:

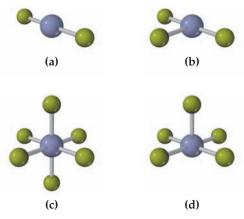

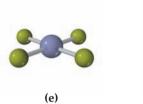

From which of the fundamental geometries shown in Figure 9.3 could you remove one or more atoms to create a molecule having this seesaw shape? [Section 9.1]

9.2 (a) If these three balloons are all the same size, what angle is formed between the red one and the green one? (b) If additional air is added to the blue balloon so that it gets larger, will the angle between the red and green balloons increase, decrease, or stay the same? (c) Which of the following aspects of the VSEPR model is illustrated by part (b): (i) The electron-domain geometry for four electron domains is tetrahedral. (ii) The electron domains for nonbonding pairs are larger than those for bonding pairs. (iii) The hybridization that corresponds to a trigonal planar electron-domain geometry is sp^2 ? [Section 9.2]

9.3 For each molecule (a)–(f), indicate how many different electron-domain geometries are consistent with the molecular geometry shown. [Section 9.2]

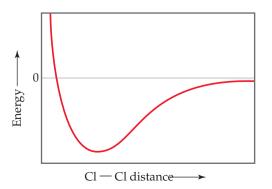

9.4 The molecule shown here is difluoromethane (CH_2F_2), which is used as a refrigerant called R-32. (a) Based on the structure, how many electron domains surround the C atom in this molecule? (b) Would the molecule have a nonzero dipole moment? (c) If the molecule is polar, which of the following describes the direction of the overall dipole moment vector in the molecule: (i) from the carbon atom toward a fluorine atom, (ii) from the carbon atom to a point midway between the fluorine atoms, (iii) from the carbon atom to a point midway between the hydrogen atoms, or (iv) From the carbon atom toward a hydrogen atom? [Sections 9.2 and 9.3]

9.5 The following plot shows the potential energy of two Cl atoms as a function of the distance between them. (a) To what does an energy of zero correspond in this diagram? (b) According to the valence-bond model, why does the energy decrease as the Cl atoms move from a large separation to a smaller one? (c) What is the significance of the Cl—Cl distance at the minimum point in the plot? (d) Why does the energy rise at Cl—Cl distances less than that at the minimum point in the plot? (e) How can you estimate the bond strength of the Cl—Cl bond from the plot? [Section 9.4]

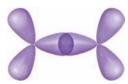

9.6 The orbital diagram that follows presents the final step in the formation of hybrid orbitals by a silicon atom. (a) Which of the following best describes what took place before the step pictured in the diagram: (i) Two 3*p* electrons became unpaired, (ii) An electron was promoted from the 2*p* orbital to the 3*s* orbital, or (iii) An electron was promoted from the 3*s* orbital to the 3*p* orbital? (b) What type of hybrid orbital is produced in this hybridization? [Section 9.5]

9.7 In the hydrocarbon

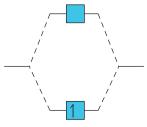

- (a) What is the hybridization at each carbon atom in the molecule? (b) How many σ bonds are there in the molecule? (c) How many π bonds? (d) Identify all the 120° bond angles in the molecule. [Section 9.6]
- **9.8** The drawing below shows the overlap of two hybrid orbitals to form a bond in a hydrocarbon. (a) Which of the following types of bonds is being formed: (i) C C σ, (ii) C C π, or (iii) C H σ? (b) Which of the following could be the identity of the hydrocarbon: (i) CH₄, (ii) C₂H₆, (iii) C₂H₄, or (iv) C₂H₂? [Section 9.6]

9.9 The molecule shown below is called *furan*. It is represented in typical shorthand way for organic molecules, with hydrogen atoms not shown.

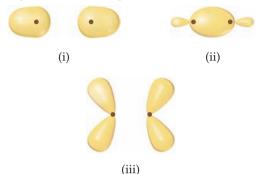

- (a) What is the molecular formula for furan? (b) How many valence electrons are there in the molecule? (c) What is the hybridization at each of the carbon atoms? (d) How many electrons are in the π system of the molecule? (e) The C—C—C bond angles in furan are much smaller than those in benzene. The likely reason is which of the following: (i) The hybridization of the carbon atoms in furan is different from that in benzene, (ii) Furan does not have another resonance structure equivalent to the one above, or (iii) The atoms in a five-membered ring are forced to adopt smaller angles than in a six-membered ring. [Section 9.5]
- **9.10** The following is part of a molecular orbital energy-level diagram for MOs constructed from 1s atomic orbitals.

(a) What labels do we use for the two MOs shown? (b) For which of the following molecules or ions could this be the energy-level diagram:

$$H_2$$
, He_2 , H_2^+ , He_2^+ , or H_2^- ?

- (c) What is the bond order of the molecule or ion? (d) If an electron is added to the system, into which of the MOs will it be added? [Section 9.7]
- **9.11** For each of these contour representations of molecular orbitals, identify (a) the atomic orbitals (*s* or *p*) used to construct the MO (b) the type of MO (σ or π), (c) whether the MO is bonding or antibonding, and (d) the locations of nodal planes. [Sections 9.7 and 9.8]

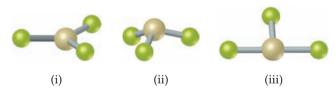

9.12 The diagram that follows shows the highest-energy occupied MOs of a neutral molecule CX, where element X is in the same row of the periodic table as C. (a) Based on the number of electrons, can you determine the identity of X? (b) Would the molecule be diamagnetic or paramagnetic? (c) Consider the π_{2p} MOs of the molecule. Would you expect them to have a greater atomic orbital contribution from C, have a greater atomic orbital contribution from X, or be an equal mixture of atomic orbitals from the two atoms? [Section 9.8]

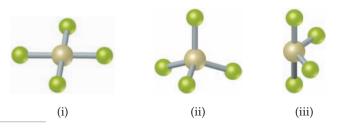

Molecular Shapes; the VSEPR Model (sections 9.1 and 9.2)

- 9.13 An AB₂ molecule is described as linear, and the A—B bond length is known. (a) Does this information completely describe the geometry of the molecule? (b) Can you tell how many nonbonding pairs of electrons are around the A atom from this information?
- **9.14** (a) Methane (CH₄) and the perchlorate ion (ClO₄⁻) are both described as tetrahedral. What does this indicate about their bond angles? (b) The NH₃ molecule is trigonal pyramidal, while BF₃ is trigonal planar. Which of these molecules is flat?
- **9.15** How does a trigonal pyramid differ from a tetrahedron so far as molecular geometry is concerned?
- 9.16 Describe the bond angles to be found in each of the following molecular structures: (a) trigonal planar, (b) tetrahedral, (c) octahedral, (d) linear.
- **9.17** (a) How does one determine the number of electron domains in a molecule or ion? (b) What is the difference between a bonding electron domain and a nonbonding electron domain?
- 9.18 Would you expect the nonbonding electron-pair domain in NH_3 to be greater or less in size than for the corresponding one in PH_3 ?

- 9.19 In which of these molecules or ions does the presence of non-bonding electron pairs produce an effect on molecular shape?(a) SiH₄, (b) PF₃, (c) HBr, (d) HCN, (e) SO₂.
- 9.20 In which of the following molecules can you confidently predict the bond angles about the central atom, and for which would you be a bit uncertain? Explain in each case. (a) H₂S, (b) BCl₃, (c) CH₃I, (d) CBr₄, (e) TeBr₄.
- **9.21** How many nonbonding electron pairs are there in each of the following molecules: (a) (CH₃)₂S, (b) HCN, (c) H₂C₂, (d) CH₃F?
- **9.22** Describe the characteristic electron-domain geometry of each of the following numbers of electron domains about a central atom: (a) 3, (b) 4, (c) 5, (d) 6.
- 9.23 Give the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom: (a) four bonding domains and no nonbonding domains, (b) three bonding domains and two nonbonding domains, (c) five bonding domains and one nonbonding domain, (d) four bonding domains and two nonbonding domains.
- 9.24 What are the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom? (a) Three bonding domains and no nonbonding domains, (b) three bonding domains and one nonbonding domain, (c) two bonding domains and two nonbonding domains.
- 9.25 Give the electron-domain and molecular geometries for the following molecules and ions: (a) HCN, (b) SO_3^{2-} , (c) SF_4 , (d) PF_6^- , (e) NH_3Cl^+ , (f) N_3^- .
- **9.26** Draw the Lewis structure for each of the following molecules or ions, and predict their electron-domain and molecular geometries: (a) AsF₃, (b) CH₃⁺, (c) BrF₃, (d) ClO₃⁻, (e) XeF₂, (f) BrO₂⁻.
- 9.27 The figure that follows shows ball-and-stick drawings of three possible shapes of an AF₃ molecule. (a) For each shape, give the electron-domain geometry on which the molecular geometry is based. (b) For each shape, how many nonbonding electron domains are there on atom A? (c) Which of the following elements will lead to an AF₃ molecule with the shape in (ii): Li, B, N, Al, P, Cl? (d) Name an element A that is expected to lead to the AF₃ structure shown in (iii). Explain your reasoning.

9.28 The figure that follows contains ball-and-stick drawings of three possible shapes of an AF₄ molecule. (a) For each shape, give the electron-domain geometry on which the molecular geometry is based. (b) For each shape, how many nonbonding electron domains are there on atom A? (c) Which of the following elements will lead to an AF₄ molecule with the shape in (iii): Be, C, S, Se, Si, Xe? (d) Name an element A that is expected to lead to the AF₄ structure shown in (i).

9.29 Give the approximate values for the indicated bond angles in the following molecules:

(b)
$$H = \begin{matrix} H \\ \downarrow \\ C \\ \vdots \\ H \end{matrix}$$

(d)
$$H \stackrel{6}{\overset{\circ}{\overset{\circ}{\longrightarrow}}} \parallel \stackrel{H}{\overset{8}{\overset{\circ}{\longrightarrow}}} H$$

9.30 Give approximate values for the indicated bond angles in the following molecules:

(a)
$$H = \ddot{\ddot{\ddot{0}}} = \ddot{\ddot{\ddot{0}}} = \ddot{\ddot{\ddot{0}}}$$

(b)
$$H \stackrel{\stackrel{3}{\longrightarrow} \stackrel{H}{\longrightarrow} \stackrel{4}{\longrightarrow} \stackrel{C}{\longrightarrow} \stackrel{C}$$

(c)
$$H = N = O = H$$

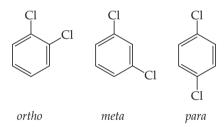

(d)
$$H - C \xrightarrow{\stackrel{H}{\downarrow}} C = N$$
:

- **9.31** The three species NH₂⁻, NH₃, and NH₄⁺ have H—N—H bond angles of 105°, 107°, and 109°, respectively. Explain this variation in bond angles.
- **9.32** In which of the following AF_n molecules or ions is there more than one F—A—F bond angle: SiF₄, PF₅, SF₄, AsF₃?
- **9.33** (a) Explain why BrF₄ is square planar, whereas BF₄ is tetrahedral. (b) How would you expect the H—X—H bond angle to vary in the series H₂O, H₂S, H₂Se? Explain. (*Hint*: The size of an electron pair domain depends in part on the electronegativity of the central atom.)
- 9.34 (a) Explain why the following ions have different bond angles: ClO₂⁻ and NO₂⁻. Predict the bond angle in each case.
 (b) Explain why the XeF₂ molecule is linear.

Shapes and Polarity of Polyatomic Molecules (section 9.3)

- **9.35** What is the distinction between a bond dipole and a molecular dipole moment?
- 9.36 Consider a molecule with formula AX₃. Supposing the A—X bond is polar, how would you expect the dipole moment of the AX₃ molecule to change as the X—A—X bond angle increases from 100° to 120°?

- **9.37** (a) Does SCl₂ have a dipole moment? If so, in which direction does the net dipole point? (b) Does BeCl₂ have a dipole moment? If so, in which direction does the net dipole point?
- **9.38** (a) The PH₃ molecule is polar. Does this offer experimental proof that the molecule cannot be planar? Explain. (b) It turns out that ozone, O_3 , has a small dipole moment. How is this possible, given that all the atoms are the same?
- **9.39** (a) What conditions must be met if a molecule with polar bonds is nonpolar? (b) What geometries will signify nonpolar molecules for AB₂, AB₃, and AB₄ geometries?
- **9.40** (a) Consider the AF $_3$ molecules in Exercise 9.27. Which of these will have a nonzero dipole moment? (b) Which of the AF $_4$ molecules in Exercise 9.28 will have a zero dipole moment?
- **9.41** Predict whether each of the following molecules is polar or nonpolar: (a) IF, (b) CS₂, (c) SO₃, (d) PCl₃, (e) SF₆, (f) IF₅.
- 9.42 Predict whether each of the following molecules is polar or nonpolar: (a) CCl₄, (b) NH₃, (c) SF₄, (d) XeF₄, (e) CH₃Br, (f) GaH₃.
- 9.43 Dichloroethylene (C₂H₂Cl₂) has three forms (isomers), each of which is a different substance. (a) Draw Lewis structures of the three isomers, all of which have a carbon–carbon double bond. (b) Which of these isomers has a zero dipole moment? (c) How many isomeric forms can chloroethylene, C₂H₃Cl, have? Would they be expected to have dipole moments?
- **9.44** Dichlorobenzene, $C_6H_4Cl_2$, exists in three forms (isomers) called *ortho, meta*, and *para*:

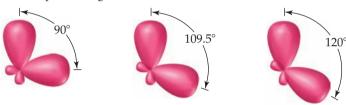

Which of these has a nonzero dipole moment?

Orbital Overlap; Hybrid Orbitals (sections 9.4 and 9.5)

- **9.45** (a) What is meant by the term *orbital overlap*? (b) Describe what a chemical bond is in terms of electron density between two atoms.
- **9.46** Draw sketches illustrating the overlap between the following orbitals on two atoms: (a) the 2s orbital on each atom, (b) the $2p_z$ orbital on each atom (assume both atoms are on the z-axis), (c) the 2s orbital on one atom and the $2p_z$ orbital on the other atom.
- 9.47 Consider the bonding in an MgH₂ molecule. (a) Draw a Lewis structure for the molecule, and predict its molecular geometry.
 (b) What hybridization scheme is used in MgH₂? (c) Sketch one of the two-electron bonds between an Mg hybrid orbital and an H 1s atomic orbital.
- **9.48** How would you expect the extent of overlap of the bonding atomic orbitals to vary in the series IF, ICl, IBr, and I₂? Explain your answer.
- **9.49** (a) Starting with the orbital diagram of a boron atom, describe the steps needed to construct hybrid orbitals appropriate

- to describe the bonding in BF₃. (b) What is the name given to the hybrid orbitals constructed in (a)? (c) Sketch the large lobes of the hybrid orbitals constructed in part (a). (d) Are any valence atomic orbitals of B left unhybridized? If so, how are they oriented relative to the hybrid orbitals?
- **9.50** (a) Starting with the orbital diagram of a sulfur atom, describe the steps needed to construct hybrid orbitals appropriate to describe the bonding in SF₂. (b) What is the name given to the hybrid orbitals constructed in (a)? (c) Sketch the large lobes of these hybrid orbitals. (d) Would the hybridization scheme in part (a) be appropriate for SF₄? Explain.
- **9.51** Indicate the hybridization of the central atom in (a) BCl₃, (b) AlCl₄⁻, (c) CS₂, (d) GeH₄.
- **9.52** What is the hybridization of the central atom in (a) SiCl₄, (b) HCN, (c) SO₃, (d) TeCl₂.
- 9.53 Shown here are three pairs of hybrid orbitals, with each set at a characteristic angle. For each pair, determine the type of hybridization, if any, that could lead to hybrid orbitals at the specified angle.

9.54 (a) Which geometry and central atom hybridization would you expect in the series BH₄⁻, CH₄, NH₄⁺? (b) What would you expect for the magnitude and direction of the bond dipoles in this series? (c) Write the formulas for the analogous species of the elements of period 3; would you expect them to have the same hybridization at the central atom?

Multiple Bonds (section 9.6)

- **9.55** (a) Draw a picture showing how two p orbitals on two different atoms can be combined to make a σ bond. (b) Sketch a π bond that is constructed from p orbitals. (c) Which is generally stronger, a σ bond or a π bond? Explain. (d) Can two s orbitals combine to form a π bond? Explain.
- **9.56** (a) If the valence atomic orbitals of an atom are sp hybridized, how many unhybridized p orbitals remain in the valence shell? How many π bonds can the atom form? (b) Imagine that you could hold two atoms that are bonded together, twist them, and not change the bond length. Would it be easier to twist (rotate) around a single σ bond or around a double (σ plus π) bond, or would they be the same?
- **9.57** (a) Draw Lewis structures for ethane (C_2H_6) , ethylene (C_2H_4) , and acetylene (C_2H_2) . (b) What is the hybridization of the carbon atoms in each molecule? (c) Predict which molecules, if any, are planar. (d) How many σ and π bonds are there in each molecule?
- 9.58 The nitrogen atoms in N₂ participate in multiple bonding, whereas those in hydrazine, N₂H₄, do not. (a) Draw Lewis structures for both molecules. (b) What is the hybridization of the nitrogen atoms in each molecule? (c) Which molecule has the stronger N—N bond?
- **9.59** Propylene, C₃H₆, is a gas that is used to form the important polymer called polypropylene. Its Lewis structure is

- (a) What is the total number of valence electrons in the propylene molecule? (b) How many valence electrons are used to make σ bonds in the molecule? (c) How many valence electrons are used to make π bonds in the molecule? (d) How many valence electrons remain in nonbonding pairs in the molecule? (e) What is the hybridization at each carbon atom in the molecule?
- **9.60** Ethyl acetate, $C_4H_8O_2$, is a fragrant substance used both as a solvent and as an aroma enhancer. Its Lewis structure is

- (a) What is the hybridization at each of the carbon atoms of the molecule? (b) What is the total number of valence electrons in ethyl acetate? (c) How many of the valence electrons are used to make σ bonds in the molecule? (d) How many valence electrons are used to make π bonds? (e) How many valence electrons remain in nonbonding pairs in the molecule?
- **9.61** Consider the Lewis structure for glycine, the simplest amino acid:

- (a) What are the approximate bond angles about each of the two carbon atoms, and what are the hybridizations of the orbitals on each of them? (b) What are the hybridizations of the orbitals on the two oxygens and the nitrogen atom, and what are the approximate bond angles at the nitrogen? (c) What is the total number of σ bonds in the entire molecule, and what is the total number of π bonds?
- **9.62** Acetylsalicylic acid, better known as aspirin, has the Lewis structure

- (a) What are the approximate values of the bond angles labeled 1, 2, and 3? (b) What hybrid orbitals are used about the central atom of each of these angles? (c) How many σ bonds are in the molecule?
- **9.63** (a) What is the difference between a localized π bond and a delocalized one? (b) How can you determine whether a molecule or ion will exhibit delocalized π bonding? (c) Is the π bond in NO₂⁻ localized or delocalized?
- **9.64** (a) Write a single Lewis structure for SO_3 , and determine the hybridization at the S atom. (b) Are there other equivalent Lewis structures for the molecule? (c) Would you expect SO_3 to exhibit delocalized π bonding?

- 9.65 In the formate ion, HCO_2^- , the carbon atom is the central atom with the other three atoms attached to it. (a) Draw a Lewis structure for the formate ion. (b) What hybridization is exhibited by the C atom? (c) Are there multiple equivalent resonance structures for the ion? (d) Which of the atoms in the ion have p_{π} orbitals? (e) How many electrons are in the π system of the ion?
- **9.66** Consider the Lewis structure shown below.

- (a) Does the Lewis structure depict a neutral molecule or an ion? If it is an ion, what is the charge on the ion? (b) What hybridization is exhibited by each of the carbon atoms? (c) Are there multiple equivalent resonance structures for the species? (d) Which of the atoms in the species have p_{π} orbitals? (e) How many electrons are in the π system of the species?
- **9.67** Predict the molecular geometry of each of the following molecules:

(a)
$$H-C\equiv C-C\equiv C-C\equiv N$$

- **9.68** What hybridization do you expect for the atom indicated in red in each of the following species?
 - (a) $CH_3CO_2^-$; (b) PH_4^+ ; (c) AlF_3 ; (d) $H_2C = CH CH_2^+$

Molecular Orbitals and Period 2 Diatomic Molecules (sections 9.7 and 9.8)

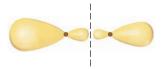

- 9.69 (a) What is the difference between hybrid orbitals and molecular orbitals? (b) How many electrons can be placed into each MO of a molecule? (c) Can antibonding molecular orbitals have electrons in them?
- 9.70 (a) If you combine two atomic orbitals on two different atoms to make a new orbital, is this a hybrid orbital or a molecular orbital? (b) If you combine two atomic orbitals on *one* atom to make a new orbital, is this a hybrid orbital or a molecular orbital? (c) Does the Pauli exclusion principle (Section 6.7) apply to MOs? Explain.
- 9.71 Consider the H₂⁺ ion. (a) Sketch the molecular orbitals of the ion and draw its energy-level diagram. (b) How many electrons are there in the H₂⁺ ion? (c) Write the electron configuration of the ion in terms of its MOs. (d) What is the bond order in H₂⁺? (e) Suppose that the ion is excited by light so that an electron moves from a lower-energy to a higher-energy MO. Would you expect the excited-state H₂⁺ ion to be stable or to fall apart? (f) Which of the following statements about part (e) is correct: (i) The light excites an electron from a bonding orbital to an antibonding orbital, (ii) The light excites an electron from an antibonding orbital to a bonding orbital, or (iii) In the excited state there are more bonding electrons than antibonding electrons?

- 9.72 (a) Sketch the molecular orbitals of the H₂⁻ ion and draw its energy-level diagram. (b) Write the electron configuration of the ion in terms of its MOs. (c) Calculate the bond order in H₂⁻. (d) Suppose that the ion is excited by light, so that an electron moves from a lower-energy to a higher-energy molecular orbital. Would you expect the excited-state H₂⁻ ion to be stable? (e) Which of the following statements about part (d) is correct: (i) The light excites an electron from a bonding orbital to an antibonding orbital, (ii) The light excites an electron from an antibonding orbital to a bonding orbital, or (iii) In the excited state there are more bonding electrons than antibonding electrons?
- **9.73** Draw a picture that shows all three 2p orbitals on one atom and all three 2p orbitals on another atom. (a) Imagine the atoms coming close together to bond. How many σ bonds can the two sets of 2p orbitals make with each other? (b) How many π bonds can the two sets of 2p orbitals make with each other? (c) How many antibonding orbitals, and of what type, can be made from the two sets of 2p orbitals?
- **9.74** (a) What is the probability of finding an electron on the internuclear axis if the electron occupies a π molecular orbital? (b) For a homonuclear diatomic molecule, what similarities and differences are there between the π_{2p} MO made from the $2p_x$ atomic orbitals and the π_{2p} MO made from the $2p_y$ atomic orbitals? (c) How do the π_{2p}^* MOs formed from the $2p_x$ and $2p_y$ atomic orbitals differ from the π_{2p} MOs in terms of energies and electron distributions?
- **9.75** (a) What are the relationships among bond order, bond length, and bond energy? (b) According to molecular orbital theory, would either Be₂ or Be₂⁺ be expected to exist? Explain.
- **9.76** Explain the following: (a) The *peroxide* ion, O_2^{-2} , has a longer bond length than the *superoxide* ion, O_2^{-1} . (b) The magnetic properties of B_2 are consistent with the π_{2p} MOs being lower in energy than the σ_{2p} MO. (c) The O_2^{-2+1} ion has a stronger O—O bond than O_2 itself.
- 9.77 (a) What does the term diamagnetism mean? (b) How does a diamagnetic substance respond to a magnetic field?
 (c) Which of the following ions would you expect to be diamagnetic: N₂²⁻, O₂²⁻, Be₂²⁺, C₂⁻?
- **9.78** (a) What does the term *paramagnetism* mean? (b) How can one determine experimentally whether a substance is paramagnetic? (c) Which of the following ions would you expect to be paramagnetic: O_2^+ , N_2^{2-} , Li_2^+ , O_2^{2-} ? For those ions that are paramagnetic, determine the number of unpaired electrons
- **9.79** Using Figures 9.35 and 9.43 as guides, draw the molecular orbital electron configuration for (a) B_2^+ , (b) Li_2^+ , (c) N_2^+ , (d) Ne_2^{2+} . In each case indicate whether the addition of an

- electron to the ion would increase or decrease the bond order of the species.
- 9.80 If we assume that the energy-level diagrams for homonuclear diatomic molecules shown in Figure 9.43 can be applied to heteronuclear diatomic molecules and ions, predict the bond order and magnetic behavior of (a) CO⁺, (b) NO⁻, (c) OF⁺, (d) NeF⁺.
- **9.81** Determine the electron configurations for CN⁺, CN, and CN⁻. (a) Which species has the strongest C—N bond? (b) Which species, if any, has unpaired electrons?
- 9.82 (a) The nitric oxide molecule, NO, readily loses one electron to form the NO⁺ ion. Which of the following is the best explanation of why this happens: (i) Oxygen is more electronegative than nitrogen, (ii) The highest energy electron in NO lies in a π_{2p}* molecular orbital, or (iii) The π_{2p}* MO in NO is completely filled. (b) Predict the order of the N O bond strengths in NO, NO⁺, and NO⁻, and describe the magnetic properties of each. (c) With what neutral homonuclear diatomic molecules are the NO⁺ and NO⁻ ions isoelectronic (same number of electrons)?
- [9.83] Consider the molecular orbitals of the P₂ molecule. Assume that the MOs of diatomics from the third row of the periodic table are analogous to those from the second row. (a) Which valence atomic orbitals of P are used to construct the MOs of P₂? (b) The figure that follows shows a sketch of one of the MOs for P₂. What is the label for this MO? (c) For the P₂ molecule, how many electrons occupy the MO in the figure? (d) Is P₂ expected to be diamagnetic or paramagnetic?

[9.84] The iodine bromide molecule, IBr, is an interhalogen compound. Assume that the molecular orbitals of IBr are analogous to the homonuclear diatomic molecule F₂. (a) Which valence atomic orbitals of I and of Br are used to construct the MOs of IBr? (b) What is the bond order of the IBr molecule? (c) One of the valence MOs of IBr is sketched here. Why are the atomic orbital contributions to this MO different in size? (d) What is the label for the MO? (e) For the IBr molecule, how many electrons occupy the MO?

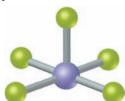

Additional Exercises

- 9.85 (a) What is the physical basis for the VSEPR model?
 (b) When applying the VSEPR model, we count a double or triple bond as a single electron domain. Why is this justified?
- **9.86** An AB₃ molecule is described as having a trigonal-bipyramidal electron-domain geometry. (a) How many nonbonding domains are on atom A? (b) Based on the information given, which of the following is the molecular geometry of
- the molecule: (i) trigonal planar, (ii) trigonal pyramidal, (iii) T-shaped, or (iv) tetrahedral?
- 9.87 Consider the following XF₄ ions: PF₄⁻, BrF₄⁻, ClF₄⁺, and AlF₄⁻.
 (a) Which of the ions have more than an octet of electrons around the central atom? (b) For which of the ions will the electron-domain and molecular geometries be the same? (c) Which of the ions will have an octahedral electron-domain geometry?
 (d) Which of the ions will exhibit a see-saw molecular geometry?

- 9.88 Consider the molecule PF₄Cl. (a) Draw a Lewis structure for the molecule, and predict its electron-domain geometry. (b) Which would you expect to take up more space, a P F bond or a P Cl bond? Explain. (c) Predict the molecular geometry of PF₄Cl. How did your answer for part (b) influence your answer here in part (c)? (d) Would you expect the molecule to distort from its ideal electron-domain geometry? If so, how would it distort?
- [9.89] The vertices of a tetrahedron correspond to four alternating corners of a cube. By using analytical geometry, demonstrate that the angle made by connecting two of the vertices to a point at the center of the cube is 109.5°, the characteristic angle for tetrahedral molecules.
- **9.90** Fill in the blank spaces in the following chart. If the molecule column is blank, find an example that fulfills the conditions of the rest of the row.

Molecule	Electron-Domain Geometry	Hybridization of Central Atom	Dipole Moment? Yes or No
CO ₂			
		sp^3	Yes
		sp^3	No
	Trigonal planar		No
SF_4			
	Octahedral		No
		sp^2	Yes
	Trigonal bipyramidal		No
XeF_2			

- **9.91** From their Lewis structures, determine the number of σ and π bonds in each of the following molecules or ions: (a) CO₂; (b) cyanogen, (CN)₂; (c) formaldehyde, H₂CO; (d) formic acid, HCOOH, which has one H and two O atoms attached to C.
- 9.92 The lactic acid molecule, $CH_3CH(OH)COOH$, gives sour milk its unpleasant, sour taste. (a) Draw the Lewis structure for the molecule, assuming that carbon always forms four bonds in its stable compounds. (b) How many π and how many σ bonds are in the molecule? (c) Which CO bond is shortest in the molecule? (d) What is the hybridization of atomic orbitals around the carbon atom associated with that short bond? (e) What are the approximate bond angles around each carbon atom in the molecule?
- **9.93** An AB₅ molecule adopts the geometry shown here. (a) What is the name of this geometry? (b) Do you think there are any nonbonding electron pairs on atom A? (c) Suppose the atoms B are halogen atoms. Of which group in the periodic table is atom A a member: (i) Group 5A, (ii) Group 6A, (iii) Group 7A, (iv) Group 8A, or (v) More information is needed?

9.94 There are two compounds of the formula $Pt(NH_3)_2Cl_2$:

The compound on the right, cisplatin, is used in cancer therapy. The compound on the left, transplatin, is ineffective for cancer therapy. Both compounds have a square-planar geometry. (a) Which compound has a nonzero dipole moment? (b) The reason cisplatin is a good anticancer drug is that it binds tightly to DNA. Cancer cells are rapidly dividing, producing a lot of DNA. Consequently, cisplatin kills cancer cells at a faster rate than normal cells. However, since normal cells also are making DNA, cisplatin also attacks healthy cells, which leads to unpleasant side effects. The way both molecules bind to DNA involves the Cl⁻ ions leaving the Pt ion, to be replaced by two nitrogens in DNA. Draw a picture in which a long vertical line represents a piece of DNA. Draw the Pt(NH₃)₂ fragments of cisplatin and transplatin with the proper shape. Also draw them attaching to your DNA line. Can you explain from your drawing why the shape of the cisplatin causes it to bind to DNA more effectively than transplatin?

- [9.95] The O—H bond lengths in the water molecule (H₂O) are 0.96 Å, and the H—O—H angle is 104.5°. The dipole moment of the water molecule is 1.85 D. (a) In what directions do the bond dipoles of the O—H bonds point? In what direction does the dipole moment vector of the water molecule point? (b) Calculate the magnitude of the bond dipole of the O—H bonds. (Note: You will need to use vector addition to do this.) (c) Compare your answer from part (b) to the dipole moments of the hydrogen halides (Table 8.3). Is your answer in accord with the relative electronegativity of oxygen?
- **9.96** The reaction of three molecules of fluorine gas with a Xe atom produces the substance xenon hexafluoride, XeF₆:

$$Xe(g) + 3 F_2(g) \rightarrow XeF_6(s)$$

- (a) Draw a Lewis structure for XeF₆. (b) If you try to use the VSEPR model to predict the molecular geometry of XeF₆, you run into a problem. What is it? (c) What could you do to resolve the difficulty in part (b)? (d) The molecule IF₇ has a pentagonal-bipyramidal structure (five equatorial fluorine atoms at the vertices of a regular pentagon and two axial fluorine atoms). Based on the structure of IF₇, suggest a structure for XeF₆.
- **9.97** Which of the following statements about hybrid orbitals is or are true? (i) After an atom undergoes sp hybridization there is one unhybridized p orbital on the atom, (ii) Under sp^2 hybridization, the large lobes point to the vertices of an equilateral triangle, and (iii) The angle between the large lobes of sp^3 hybrids is 109.5°.
- [9.98] The Lewis structure for allene is

$$C = C = C$$

Make a sketch of the structure of this molecule that is analogous to Figure 9.25. In addition, answer the following three questions: (a) Is the molecule planar? (b) Does it have a nonzero dipole moment? (c) Would the bonding in allene be described as delocalized? Explain.

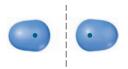

9.99 Consider the molecule C_4H_5N , which has the connectivity shown below. (a) After the Lewis structure for the molecule is completed, how many σ and how many π bonds are there in this molecule? (b) How many atoms in the molecule exhibit (i) sp hybridization, (ii) sp^2 hybridization, and (iii) sp^3 hybridization?

395

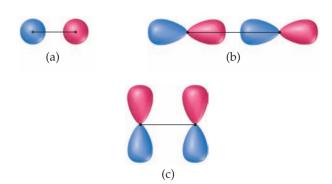

- [9.100] The azide ion, N₃⁻, is linear with two N—N bonds of equal length, 1.16 Å. (a) Draw a Lewis structure for the azide ion. (b) With reference to Table 8.5, is the observed N—N bond length consistent with your Lewis structure? (c) What hybridization scheme would you expect at each of the nitrogen atoms in N₃⁻? (d) Show which hybridized and unhybridized orbitals are involved in the formation of σ and π bonds in N₃⁻. (e) It is often observed that σ bonds that involve an *sp* hybrid orbital are shorter than those that involve only *sp*² or *sp*³ hybrid orbitals. Can you propose a reason for this? Is this observation applicable to the observed bond lengths in N₃⁻?
- [9.101] In ozone, O_3 , the two oxygen atoms on the ends of the molecule are equivalent to one another. (a) What is the best choice of hybridization scheme for the atoms of ozone? (b) For one of the resonance forms of ozone, which of the orbitals are used to make bonds and which are used to hold nonbonding pairs of electrons? (c) Which of the orbitals can be used to delocalize the π electrons? (d) How many electrons are delocalized in the π system of ozone?
- **9.102** Butadiene, C_4H_6 , is a planar molecule that has the following carbon–carbon bond lengths:

$$H_2C \underline{\hspace{1cm}}_{1.34 \, \mathring{A}} CH \underline{\hspace{1cm}}_{1.48 \, \mathring{A}} CH \underline{\hspace{1cm}}_{1.34 \, \mathring{A}} CH_2$$

- (a) Predict the bond angles around each of the carbon atoms and sketch the molecule.
- **(b)** Compare the bond lengths to the average bond lengths listed in Table 8.5. Can you explain any differences?
- **9.103** The structure of *borazine*, B₃N₃H₆, is a six-membered ring of alternating B and N atoms. There is one H atom bonded to each B and to each N atom. The molecule is planar. (a) Write a Lewis structure for borazine in which the formal charges on every atom is zero. (b) Write a Lewis structure for borazine in which the octet rule is satisfied for every atom. (c) What are the formal charges on the atoms in the Lewis structure from part (b)? Given the electronegativities of B and N, do the formal charges seem favorable or unfavorable? (d) Do either of the Lewis structures in parts (a) and (b) have multiple resonance structures? (e) What are the hybridizations at the B and N atoms in the Lewis structures from parts (a) and (b)? Would you expect the molecule to be planar for both Lewis structures? (f) The six B—N bonds in the borazine molecule are all identical in length at 1.44 Å. Typical values for the bond lengths of B — N single and double bonds are 1.51 Å and 1.31 Å, respectively. Does the value of the B—N bond length seem to favor one Lewis structure over the other? (g) How many electrons are in the π system of borazine?
- **9.104** Suppose that silicon could form molecules that are precisely the analogs of ethane (C_2H_6) , ethylene (C_2H_4) , and acetylene (C_2H_2) . How would you describe the bonding about Si in terms of hydrid orbitals? Silicon does not readily form some of the analogous compounds containing π bonds. Why might this be the case?
- **9.105** One of the molecular orbitals of the H_2^- ion is sketched below:

- (a) Is the molecular orbital a σ or π MO? Is it bonding or antibonding? (b) In H_2^- , how many electrons occupy the MO shown above? (c) What is the bond order in the H_2^- ion? (d) Compared to the H—H bond in H_2 , the H—H bond in H_2^- is expected to be which of the following: (i) Shorter and stronger, (ii) longer and stronger, (iii) shorter and weaker, (iv) longer and weaker, or (v) the same length and strength?
- **9.106** Place the following molecules and ions in order from smallest to largest bond order: H_2^+ , B_2 , N_2^+ , F_2^+ , and Ne_2 .
- [9.107] The following sketches show the atomic orbital wave functions (with phases) used to construct some of the MOs of a homonuclear diatomic molecule. For each sketch, determine the type of MO that will result from mixing the atomic orbital wave functions as drawn. Use the same labels for the MOs as in the "Closer Look" box on phases.

- 9.108 Write the electron configuration for the first excited state for N₂; that is, the state with the highest-energy electron moved to the next available energy level. (a) Is the nitrogen in its first excited state diamagnetic or paramagnetic? (b) Is the N—N bond strength in the first excited state stronger or weaker compared to that in the ground state?
- **9.109** Azo dyes are organic dyes that are used for many applications, such as the coloring of fabrics. Many azo dyes are derivatives of the organic substance azobenzene, $C_{12}H_{10}N_2$. A closely related substance is hydrazobenzene, $C_{12}H_{10}N_2$. The Lewis structures of these two substances are

Azobenzene

Hydrazobenzene

(Recall the shorthand notation used for benzene.) (a) What is the hybridization at the N atom in each of the substances? (b) How many unhybridized atomic orbitals are there on the N and the C atoms in each of the substances? (c) Predict the N—N—C angles in each of the substances. (d) Azobenzene is said to have greater delocalization of its π electrons than hydrazobenzene. Discuss this statement in light of your answers to (a) and (b). (e) All the atoms of azobenzene lie in one plane, whereas those of hydrazobenzene do not. Is this observation consistent with the statement in part (d)? (f) Azobenzene is an intense red-orange color, whereas hydrazobenzene is nearly colorless. Which molecule would be a better one to use in a solar energy conversion device? (See the "Chemistry Put to Work" box for more information about solar cells.)

- [9.110] (a) Using only the valence atomic orbitals of a hydrogen atom and a fluorine atom, and following the model of Figure 9.46, how many MOs would you expect for the HF molecule? (b) How many of the MOs from part (a) would be occupied by electrons? (c) It turns out that the difference in energies between the valence atomic orbitals of H and F are sufficiently different that we can neglect the interaction of the 1s orbital of hydrogen with the 2s orbital of fluorine. The 1s orbital of hydrogen will mix only with one 2p orbital of fluorine. Draw pictures showing the proper orientation of all three 2p orbitals on F interacting with a 1s orbital on H. Which of the 2p orbitals can actually make a bond with a 1s orbital, assuming that the atoms lie on the z-axis? (d) In the most accepted picture of HF, all the other atomic orbitals on fluorine move over at the same energy into the molecular orbital energy-level diagram for HF. These are called "nonbonding orbitals." Sketch the energy-level diagram for HF using this information and calculate the bond order. (Nonbonding electrons do not contribute to bond order.) (e) Look at the Lewis structure for HF. Where are the nonbonding electrons?
- [9.111] Carbon monoxide, CO, is isoelectronic to N_2 . (a) Draw a Lewis structure for CO that satisfies the octet rule. (b) Assume that the diagram in Figure 9.46 can be used to describe the MOs of

- CO. What is the predicted bond order for CO? Is this answer in accord with the Lewis structure you drew in part (a)? (c) Experimentally, it is found that the highest-energy electrons in CO reside in a σ -type MO. Is that observation consistent with Figure 9.46? If not, what modification needs to be made to the diagram? How does this modification relate to Figure 9.43? (d) Would you expect the π_{2p} MOs of CO to have equal atomic orbital contributions from the C and O atoms? If not, which atom would have the greater contribution?
- 9.112 The energy-level diagram in Figure 9.36 shows that the side-ways overlap of a pair of p orbitals produces two molecular orbitals, one bonding and one antibonding. In ethylene there is a pair of electrons in the bonding p orbital between the two carbons. Absorption of a photon of the appropriate wavelength can result in promotion of one of the bonding electrons from the π_{2p} to the π_{2p}^* molecular orbital. (a) What would you expect this electronic transition to do to the carbon–carbon bond order in ethylene? (b) How does this relate to the fact that absorption of a photon of appropriate wavelength can cause ready rotation about the carbon–carbon bond, as described in the "Chemistry and Life" box and shown in Figure 9.30?

Integrative Exercises

- **9.113** A compound composed of 2.1% H, 29.8% N, and 68.1% O has a molar mass of approximately 50 g/mol. (a) What is the molecular formula of the compound? (b) What is its Lewis structure if H is bonded to O? (c) What is the geometry of the molecule? (d) What is the hybridization of the orbitals around the N atom? (e) How many σ and how many π bonds are there in the molecule?
- **9.114** Sulfur tetrafluoride (SF₄) reacts slowly with O₂ to form sulfur tetrafluoride monoxide (OSF₄) according to the following unbalanced reaction:

$$SF_4(g) + O_2(g) \longrightarrow OSF_4(g)$$

The O atom and the four F atoms in OSF_4 are bonded to a central S atom. (a) Balance the equation. (b) Write a Lewis structure of OSF_4 in which the formal charges of all atoms are zero. (c) Use average bond enthalpies (Table 8.4) to estimate the enthalpy of the reaction. Is it endothermic or exothermic? (d) Determine the electron-domain geometry of OSF_4 , and write two possible molecular geometries for the molecule based on this electron-domain geometry. (e) Which of the molecular geometries in part (d) is more likely to be observed for the molecule? Explain.

- [9.115] The phosphorus trihalides (PX₃) show the following variation in the bond angle X-P-X: PF₃, 96.3°; PCl₃, 100.3°; PBr₃, 101.0°; PI₃, 102.0°. The trend is generally attributed to the change in the electronegativity of the halogen. (a) Assuming that all electron domains are the same size, what value of the X-P-X angle is predicted by the VSEPR model? (b) What is the general trend in the X-P-X angle as the halide electronegativity increases? (c) Using the VSEPR model, explain the observed trend in X-P-X angle as the electronegativity of X changes. (d) Based on your answer to part (c), predict the structure of PBrCl₄.
- [9.116] The molecule 2-butene, C_4H_8 , can undergo a geometric change called *cis-trans isomerization*:

$$C = C$$
 $C \mapsto C$
 $C \mapsto$

As discussed in the "Chemistry and Life" box on the chemistry of vision, such transformations can be induced by light and are the key to human vision. (a) What is the hybridization at the two central carbon atoms of 2-butene? (b) The isomerization occurs by rotation about the central C—C bond. With reference to Figure 9.30, explain why the π bond between the two central carbon atoms is destroyed halfway through the rotation from cis- to trans-2-butene. (c) Based on average bond enthalpies (Table 8.4), how much energy per molecule must be supplied to break the C—C π bond? (d) What is the longest wavelength of light that will provide photons of sufficient energy to break the C—C π bond and cause the isomerization? (e) Is the wavelength in your answer to part (d) in the visible portion of the electromagnetic spectrum? Comment on the importance of this result for human vision.

- 9.117 (a) Compare the bond enthalpies (Table 8.4) of the carbon–carbon single, double, and triple bonds to deduce an average π-bond contribution to the enthalpy. What fraction of a single bond does this quantity represent? (b) Make a similar comparison of nitrogen–nitrogen bonds. What do you observe? (c) Write Lewis structures of N₂H₄, N₂H₂, and N₂, and determine the hybridization around nitrogen in each case. (d) Propose a reason for the large difference in your observations of parts (a) and (b).
- **9.118** Use average bond enthalpies (Table 8.4) to estimate ΔH for the atomization of benzene, C_6H_6 :

$$C_6H_6(g) \longrightarrow 6 C(g) + 6 H(g)$$

Compare the value to that obtained by using ΔH_f° data given in Appendix C and Hess's law. To what do you attribute the large discrepancy in the two values?

[9.119] Many compounds of the transition-metal elements contain direct bonds between metal atoms. We will assume that the z-axis is defined as the metal-metal bond axis. (a) Which of the 3d orbitals (Figure 6.23) can be used to make a σ bond between metal atoms? (b) Sketch the σ_{3d} bonding and σ_{3d}^* antibonding MOs. (c) With reference to the "Closer Look"

box on the phases of orbitals, explain why a node is generated in the σ_{3d}^* MO. (d) Sketch the energy-level diagram for the Sc₂ molecule, assuming that only the 3*d* orbital from part (a) is important. (e) What is the bond order in Sc₂?

[9.120] The organic molecules shown here are derivatives of benzene in which six-membered rings are "fused" at the edges of the hexagons.

(a) Determine the empirical formula of benzene and of these three compounds. (b) Suppose you are given a sample of one of the compounds. Could combustion analysis be used to determine unambiguously which of the three it is? (c) Naphthalene, the active ingredient in mothballs, is a white solid. Write a balanced equation for the combustion of naphthalene to $CO_2(g)$ and $H_2O(g)$. (d) Using the Lewis structure for naphthalene and the average bond enthalpies in Table 8.4, estimate the heat of combustion of naphthalene in kJ/mol. (e) Would you expect naphthalene, anthracene, and tetracene to have multiple resonance structures? If so, draw the additional resonance structures for naphthalene. (f) Benzene, naphthalene,

and anthracene are colorless, but tetracene is orange. What does this imply about the relative HOMO-LUMO energy gaps in these molecules? See the "Chemistry Put to Work" box on orbitals and energy.

[9.121] Antibonding molecular orbitals can be used to make bonds to other atoms in a molecule. For example, metal atoms can use appropriate d orbitals to overlap with the π_{2p}^{\star} orbitals of the carbon monoxide molecule. This is called $d-\pi$ backbonding. (a) Draw a coordinate axis system in which the y-axis is vertical in the plane of the paper and the x-axis horizontal. Write "M" at the origin to denote a metal atom. (b) Now, on the xaxis to the right of M, draw the Lewis structure of a CO molecule, with the carbon nearest the M. The CO bond axis should be on the x-axis. (c) Draw the CO π_{2p}^* orbital, with phases (see the "Closer Look" box on phases) in the plane of the paper. Two lobes should be pointing toward M. (d) Now draw the d_{xy} orbital of M, with phases. Can you see how they will overlap with the π_{2p}^* orbital of CO? (e) What kind of bond is being made with the orbitals between M and C, σ or π ? (f) Predict what will happen to the strength of the CO bond in a metal-CO complex compared to CO alone.

9.122 Methyl isocyanate, CH₃NCO, was made infamous in 1984 when an accidental leakage of this compound from a storage tank in Bhopal, India, resulted in the deaths of about 3,800 people and severe and lasting injury to many thousands more. (a) Draw a Lewis structure for methyl isocyanate. (b) Draw a ball-and-stick model of the structure, including estimates of all the bond angles in the compound. (c) Predict all the bond distances in the molecule. (d) Do you predict that the molecule will have a dipole moment? Explain.

Design an Experiment

In this chapter we have seen a number of new concepts, including the delocalization of π systems of molecules and the molecular orbital description of molecular bonding. A connection between these concepts is provided by the field of *organic dyes*, molecules with delocalized π systems that have color. The color is due to the

excitation of an electron from the *highest occupied molecular orbital* (HOMO) to the *lowest unoccupied molecular orbital* (LUMO). It is hypothesized that the energy gap between the HOMO and the LUMO depends on the length of the π system. Imagine that you are given samples of the following substances to test this hypothesis:

 β -carotene is the substance chiefly responsible for the bright orange color of carrots. It is also an important nutrient for the body's production of retinal (see the "Chemistry and Life" box in Section 9.6). (a) What experiments could you design to determine the amount of energy needed to excite an electron from the HOMO to the LUMO in each of these molecules? (b) How might you graph your data to determine whether a relationship exists between the length of the π system and

the excitation energy? (c) What additional molecules might you want to procure to further test the ideas developed here? (d) How could you design an experiment to determine whether the delocalized π systems and not some other molecular features, such as molecular length or the presence of π bonds, are important in making the excitations occur in the visible portion of the spectrum? (*Hint*: You might want to test some additional molecules not shown here.)

Gases

Hydrogen and helium make up over 98% of the Sun's mass and are the most abundant elements in the universe. The small black circle in the upper left is the planet Venus passing between the Sun and the Earth, a rare event that occurred in June of 2012 and will not occur again until 2117. The gases that make up the atmospheres of the inner planets like Venus have a very different composition from that of the Sun.

With the aid of sophisticated measuring instruments, astronomers have been able to discern significant differences in the atmospheres of the planets that make up our solar system. It is thought that the atmospheres of all of the planets initially consisted of largely hydrogen and helium, the two most abundant elements in the universe and the primary components of the Sun. The outer planets, those that are furthest from the Sun—Jupiter, Saturn, Uranus, and Neptune—can still reasonably be described as large balls of hydrogen and helium (which is why they are also known as the "gas giants"). The outer planets contain smaller amounts of other gases as well, including methane, which is responsible for the blue color of Uranus and Neptune.

The atmospheres of the inner planets—Mercury, Venus, Earth, and Mars—have changed dramatically and in quite different ways since the early days of the solar system. As the Sun matured, it became hotter, thereby warming the planetary atmospheres. As we will learn in this chapter, when the temperature of a gas increases its molecules move faster, an effect that becomes more pronounced for gases with low molecular weights, like H_2 and He. The heating effect was largest for the planets closer to the Sun, and the pull of gravity exerted by the smaller inner planets was not strong enough to keep these lightest of gas molecules from escaping into space.

The atmosphere that we find on the Earth today traces its origins to volcanic activity that released gases like CO_2 , H_2O , and N_2 into the atmosphere. The temperature and gravity of the Earth are such that these heavier molecules cannot escape. Much of the

▶ THE TRANSIT OF VENUS occurs when Venus passes directly between the Earth and the Sun. The small black circle in the upper right is the shadow of Venus passing in front of the Sun.

10.1 CHARACTERISTICS OF GASES We begin by comparing the distinguishing characteristics of gases with those of liquids and solids.

10.2 PRESSURE We study gas *pressure*, the units used to express it, and consider Earth's atmosphere and the pressure it exerts.

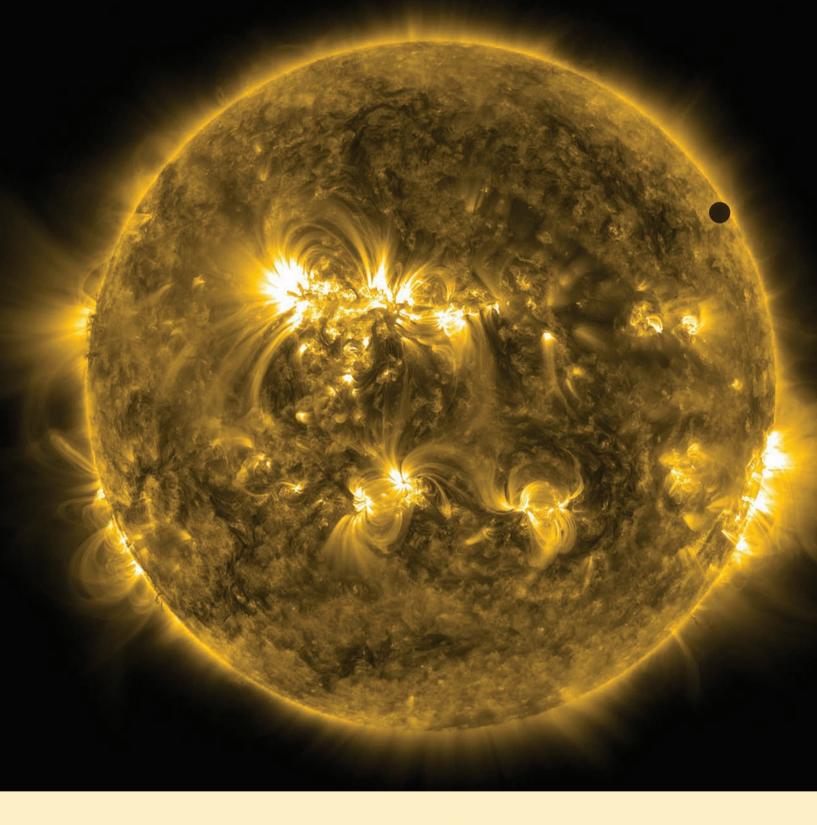

10.3 THE GAS LAWS We see that the state of a gas can be expressed in terms of its volume, pressure, temperature, and quantity and examine several *gas laws*, which are empirical relationships among these four variables.

10.4 THE IDEAL-GAS EQUATION We find that the gas laws yield the *ideal-gas equation*, PV = nRT. Although this equation is not obeyed exactly by any real gas, most gases come very close to obeying it at ordinary temperatures and pressures.

10.5 FURTHER APPLICATIONS OF THE

IDEAL-GAS EQUATION We use the ideal-gas equation in many calculations, such as the calculation of the density or molar mass of a gas.

10.6 GAS MIXTURES AND PARTIAL PRESSURES We recognize that in a mixture of gases, each gas exerts a pressure that is part of the total pressure. This partial pressure is the pressure the gas would exert if it were by itself.

10.7 THE KINETIC-MOLECULAR THEORY OF GASES We see how the behavior of gases at the molecular level is responsible for their macroscopic properties. According to the theory, the atoms or molecules that make up a gas are in constant random motion and move with an average kinetic energy that is proportional to the temperature of the gas.

10.8 MOLECULAR EFFUSION AND DIFFUSION We observe that the kinetic-molecular theory helps account for such gas properties as *effusion* and *diffusion*.

10.9 REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR We learn that real gases deviate from ideal behavior because the gas molecules have finite volume and because attractive forces exist between molecules. The *van der Waals equation* accounts for real gas behavior at high pressures and low temperatures.

water vapor in early Earth's atmosphere condensed to form the oceans, and much of the CO_2 was dissolved in the ocean and went on to form carbonate minerals, leaving an atmosphere rich in N_2 . Once life arose, plant photosynthesis produced O_2 so that now we have an atmosphere that is approximately 78% N_2 and 21% O_2 . The hotter conditions on Venus led it down a very different path to a dense atmosphere that is 97% CO_2 with very little O_2 and inhospitable features like sulfuric acid clouds.

In this chapter, we will look more closely at the characteristics of gases as chemical systems. We will explore the macroscopic properties that we associate with gases—such as pressure—and see how these relate to the picture of a gas as a collection of molecules or atoms in random motion.

10.1 | Characteristics of Gases

In many ways, gases are the most easily understood form of matter. Even though different gaseous substances may have very different *chemical* properties, they behave quite similarly as far as their *physical* properties are concerned. For example, the N_2 and O_2 that account for approximately 99% of our atmosphere have very different chemical properties— O_2 supports human life but N_2 does not, to name just one difference—but these two components of air behave physically as one gaseous material because their physical properties are essentially identical. Of the few elements that exist as gases at ordinary temperatures and pressures, He, Ne, Ar, Kr, and Xe are monatomic and H_2 , N_2 , O_2 , F_2 , and Cl_2 are diatomic. Many molecular compounds are gases, and \blacksquare Table 10.1 lists a few of them. Notice that all of these gases are composed entirely of nonmetallic elements. Furthermore, all have simple molecular formulas and, therefore, low molar masses.

Substances that are liquids or solids under ordinary conditions can also exist in the gaseous state, where they are often referred to as **vapors**. The substance H_2O , for example, can exist as liquid water, solid ice, or water vapor.

Gases differ significantly from solids and liquids in several respects. For example, a gas expands spontaneously to fill its container. Consequently, the volume of a gas equals the volume of its container. Gases also are highly compressible: When pressure is applied to a gas, its volume readily decreases. Solids and liquids, on the other hand, do not expand to fill their containers and are not readily compressible.

Two or more gases form a homogeneous mixture regardless of the identities or relative proportions of the gases; the atmosphere serves as an excellent example. Two or more liquids or two or more solids may or may not form homogeneous mixtures, depending on their chemical nature. For example, when water and gasoline are mixed, the two liquids remain as separate layers. In contrast, the water vapor and gasoline vapors above the liquids form a homogeneous gas mixture.

Table 10.1	Some Common Compounds That Are Gases at Room	
Temperature		

Formula	Name	Characteristics
HCN	Hydrogen cyanide	Very toxic, slight odor of bitter almonds
H_2S	Hydrogen sulfide	Very toxic, odor of rotten eggs
CO	Carbon monoxide	Toxic, colorless, odorless
CO_2	Carbon dioxide	Colorless, odorless
CH_4	Methane	Colorless, odorless, flammable
C_2H_4	Ethene (Ethylene)	Colorless, ripens fruit
C_3H_8	Propane	Colorless, odorless, bottled gas
N_2O	Nitrous oxide	Colorless, sweet odor, laughing gas
NO_2	Nitrogen dioxide	Toxic, red-brown, irritating odor
NH_3	Ammonia	Colorless, pungent odor
SO_2	Sulfur dioxide	Colorless, irritating odor

The characteristic properties of gases—expanding to fill a container, being highly compressible, forming homogeneous mixtures—arise because the molecules are relatively far apart. In any given volume of air, for example, the molecules take up only about 0.1% of the total volume with the rest being empty space. Thus, each molecule behaves largely as though the others were not present. As a result, different gases behave similarly even though they are made up of different molecules.

Give It Some Thought

Xenon is the heaviest stable noble gas with a molar mass of $131\,\mathrm{g/mol}$. Do any of the gases listed in Table 10.1 have molar masses larger than Xe?

10.2 | Pressure

In everyday terms, **pressure** conveys the idea of force, a push that tends to move something in a given direction. Pressure, *P*, is defined in science as the force, *F*, that acts on a given area, *A*.

$$P = \frac{F}{A} \tag{10.1}$$

Gases exert a pressure on any surface with which they are in contact. The gas in an inflated balloon, for example, exerts a pressure on the inside surface of the balloon.

Atmospheric Pressure and the Barometer

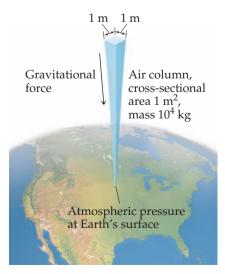

People, coconuts, and nitrogen molecules all experience an attractive gravitational force that pulls them toward the center of the Earth. When a coconut comes loose from a tree, for example, this force causes the coconut to be accelerated toward Earth, its speed increasing as its potential energy is converted into kinetic energy. (Section 5.1) The gas atoms and molecules of the atmosphere also experience a gravitational acceleration. Because these particles have such tiny masses, however, their thermal energies of motion (their kinetic energies) override the gravitational forces, so the particles that make up the atmosphere don't pile up at the Earth's surface. Nevertheless, the gravitational force does operate, and it causes the atmosphere as a whole to press down on the Earth's surface, creating atmospheric pressure, defined as the force exerted by the atmosphere on a given surface area.

You can demonstrate the existence of atmospheric pressure with an empty plastic water bottle. If you suck on the mouth of the empty bottle, chances are you can cause the bottle to partially cave in. When you break the partial vacuum you have created, the bottle pops out to its original shape. The bottle caves in because, once you've sucked out some of the air molecules, the air molecules in the atmosphere exert a force on the outside of the bottle that is greater than the force exerted by the lesser number of air molecules inside the bottle. We calculate the magnitude of this atmospheric pressure as follows: The force, F, exerted by any object is the product of its mass, m, and its acceleration, a: F = ma. The acceleration given by Earth's gravitational force to any object located near the Earth's surface is 9.8 m/s^2 . Now imagine a column of air, 1 m^2 in cross section, extending through the entire atmosphere (\blacktriangleright Figure 10.1). That column has a mass of roughly 10,000 kg. The downward gravitational force exerted on this column is

$$F = (10,000 \,\mathrm{kg})(9.8 \,\mathrm{m/s^2}) = 1 \times 10^5 \,\mathrm{kg \cdot m/s^2} = 1 \times 10^5 \,\mathrm{N}$$

where N is the abbreviation for *newton*, the SI unit for force: $1 \text{ N} = 1 \text{ kg-m/s}^2$. The pressure exerted by the column is this force divided by the cross-sectional area, A, over which the force is applied. Because our air column has a cross-sectional area of 1 m^2 , we have for the magnitude of atmospheric pressure at sea level

$$P = \frac{F}{A} = \frac{1 \times 10^5 \,\mathrm{N}}{1 \,\mathrm{m}^2} = 1 \times 10^5 \,\mathrm{N/m^2} = 1 \times 10^5 \,\mathrm{Pa} = 1 \times 10^2 \,\mathrm{kPa}$$

▲ Figure 10.1 Calculating atmospheric pressure.

The SI unit of pressure is the **pascal** (Pa), named for Blaise Pascal (1623–1662), a French scientist who studied pressure: $1 \text{ Pa} = 1 \text{ N/m}^2$. A related pressure unit is the **bar:** $1 \text{ bar} = 10^5 \text{ Pa} = 10^5 \text{ N/m}^2$. Thus, the atmospheric pressure at sea level we just calculated, 100 kPa, can be reported as 1 bar. (The actual atmospheric pressure at any location depends on weather conditions and altitude.) Another pressure unit is pounds per square inch (psi, lbs/in.²). At sea level, atmospheric pressure is 14.7 psi.

Give It Some Thought

Assume the top of your head has a surface area of $25\,\mathrm{cm}\times25\,\mathrm{cm}$. How many pounds of air are you carrying on your head if you are at sea level?

In the seventeenth century, many scientists and philosophers believed that the atmosphere had no weight. Evangelista Torricelli (1608–1647), a student of Galileo's, proved this untrue. He invented the *barometer* (**Figure 10.2**), which is made from a glass tube more than 760 mm long that is closed at one end, completely filled with mercury, and inverted into a dish of mercury. (Care must be taken so that no air gets into the tube.) When the tube is inverted into the dish, some of the mercury flows out of the tube, but a column of mercury remains in the tube. Torricelli argued that the mercury surface in the dish experiences the full force of Earth's atmosphere, which pushes the mercury up the tube until the pressure exerted by the mercury column downward, due to gravity, equals the atmospheric pressure at the base of the tube. Therefore the height, *h*, of the mercury column is a measure of atmospheric pressure and changes as atmospheric pressure changes.

Although Torricelli's explanation met with fierce opposition, it also had supporters. Blaise Pascal, for example, had one of Torricelli's barometers carried to the top of a mountain and compared its reading there with the reading on a duplicate barometer at the base of the mountain. As the barometer was carried up, the height of the mercury column diminished, as expected, because the amount of atmosphere pressing down on the mercury in the dish decreased as the instrument was carried higher. These and other experiments eventually prevailed, and the idea that the atmosphere has weight became accepted.

Standard atmospheric pressure, which corresponds to the typical pressure at sea level, is the pressure sufficient to support a column of mercury 760 mm high. In SI units, this pressure is 1.01325×10^5 Pa. Standard atmospheric pressure defines some common non-SI units used to express gas pressure, such as the **atmosphere** (atm) and the *millimeter of mercury* (mm Hg). The latter unit is also called the **torr**, after Torricelli: 1 torr = 1 mm Hg. Thus, we have

 $1 \text{ atm} = 760. \text{ mm Hg} = 760. \text{ torr} = 1.01325 \times 10^5 \text{ Pa} = 101.325 \text{ kPa} = 1.01325 \text{ bar}$

We will express gas pressure in a variety of units throughout this chapter, so you should become comfortable converting pressures from one unit to another.

Give It Some Thought

Convert a pressure of 745 torr to a pressure in (a) mm Hg, (b) atm, (c) kPa, (d) bar.

SAMPLE EXERCISE 10.1 Torricelli's Barometer

Torricelli used mercury in his barometer because it has a very high density, which makes it possible to make a more compact barometer than one based on a less dense fluid. Calculate the density of mercury, $d_{\rm Hg}$, using the observation that the column of mercury is 760 mm high when the atmospheric pressure is 1.01 \times 10⁵ Pa. Assume the tube containing the mercury is a cylinder with a constant cross-sectional area.

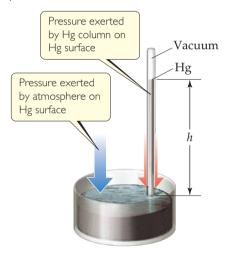

SOLUTION

Analyze Torricelli's barometer is based on the principle that the pressure exerted by the atmosphere is equal to the pressure exerted by the mercury column. The latter quantity originates from the force of gravity acting on the mass of mercury in the column. By setting these two pressures equal to each other and cancelling variables, we can solve for the density of mercury, provided we use appropriate units.

A GO

GO FIGURE

What happens to *h*, the height of the mercury column, if the atmospheric pressure increases?

▲ Figure 10.2 A mercury barometer.

Plan We will use Equation 10.1 to determine the pressure exerted by the mercury column and look to introduce density as a variable using the fact that d = m/V.

Solve We begin by calculating the pressure exerted by the mercury column, using Equation 10.1, and the knowledge that the force exerted by the mercury column is its mass multiplied by the acceleration of gravity near the Earth's surface, $(F = m \times g)$:

$$P_{\rm Hg} = \frac{F}{A} = \frac{m_{\rm Hg}g}{A}$$

The mass of the mercury is equal to its density times the volume of the mercury column. The expression can be simplified by recognizing that the volume of the column can be written in terms of its height and cross-sectional area ($V = h \times A$), which allows us to cancel the crosssectional area, which we do not know:

$$P_{\rm Hg} = \frac{m_{\rm Hg}g}{A} = \frac{d_{\rm Hg}Vg}{A} = \frac{d_{\rm Hg}(hA)g}{A} = d_{\rm Hg}hg$$

We now set the pressure of the mercury column equal to atmospheric pressure

$$P_{\rm atm} = P_{\rm Hg} = d_{\rm Hg} hg$$

Finally, we rearrange this expression to solve for $d_{\rm Hg}$ and substitute the appropriate values for the other variables. We can reduce the units of pressure down to base SI units $(Pa = N/m^2 = (kg-m/s^2)/m^2 = kg/m-s^2)$:

$$d_{\text{Hg}} = \frac{P_{\text{atm}}}{hg} = \frac{1.01 \times 10^5 \,\text{kg/m-s}^2}{(0.760 \,\text{m})(9.81 \,\text{m/s}^2)} = 1.35 \times 10^4 \,\text{kg/m}^3$$

Check Water has a density of 1.00 g/cm³, which can be converted to 1000 kg/m³. Our estimate that the density of mercury is 14 times higher than water seems reasonable, given the fact that the molar mass of Hg is approximately 11 times larger than water.

Comment We see from this analysis that the height of the column does not depend upon its cross-sectional area, provided the area does not change along the height of the column.

Practice Exercise 1

What would be the height of the column if the external pressure was 101 kPa and water $(d = 1.00 \text{ g/cm}^3)$ was used in place of mercury? (a) 0.0558 m, (b) 0.760 m, (c) 1.03×10^4 m, (d) 10.3 m, (e) 0.103 m.

Practice Exercise 2

Gallium melts just above room temperature and is liquid over a very wide temperature range (30–2204 °C), which means it would be a suitable fluid for a high-temperature barometer. Given its density, $d_{Ga} = 6.0 \text{ g/cm}^3$, what would be the height of the column if gallium is used as the barometer fluid and the external pressure is 9.5×10^4 Pa?

We use various devices to measure the pressures of enclosed gases. Tire gauges, for example, measure the pressure of air in automobile and bicycle tires. In laboratories, we sometimes use a manometer, which operates on a principle similar to that of a barometer, as shown in Sample Exercise 10.2.

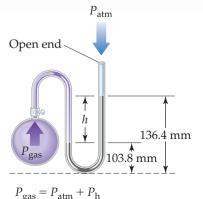

SAMPLE EXERCISE 10.2

Using a Manometer to Measure Gas Pressure

On a certain day, a laboratory barometer indicates that the atmospheric pressure is 764.7 torr. A sample of gas is placed in a flask attached to an open-end mercury manometer (> Figure 10.3), and a meter stick is used to measure the height of the mercury in the two arms of the U tube. The height of the mercury in the open ended arm is 136.4 mm, and the height in the arm in contact with the gas in the flask is 103.8 mm. What is the pressure of the gas in the flask (a) in atmospheres, (b) in kilopascals?

SOLUTION

Analyze We are given the atmospheric pressure (764.7 torr) and the mercury heights in the two arms of the manometer and asked to determine the gas pressure in the flask. Recall that millimeters of mercury is a pressure unit. We know that the gas pressure from the flask must be greater than atmospheric pressure because the mercury level in the arm on the flask side (103.8 mm) is lower than the level in the arm open to the atmosphere (136.4 mm). Therefore, the gas from the flask is pushing mercury from the arm in contact with the flask into the arm open to the atmosphere.

 $P_{\rm gas} = P_{\rm atm} + P_{\rm h}$

▲ Figure 10.3 A mercury manometer.

Plan We will use the difference in height between the two arms (*h* in Figure 10.3) to obtain the amount by which the pressure of the gas exceeds atmospheric pressure. Because an open-end mercury manometer is used, the height difference directly measures the pressure difference in mm Hg or torr between the gas and the atmosphere.

Solve

(a) The pressure of the gas equals the atmospheric pressure plus h:

$$P_{\text{gas}} = P_{\text{atm}} + h$$

= 764.7 torr + (136.4 torr - 103.8 torr)
= 797.3 torr

We convert the pressure of the gas to atmospheres:

 $P_{\text{gas}} = (797.3 \, \text{torr}) \left(\frac{1 \, \text{atm}}{760 \, \text{torr}} \right) = 1.049 \, \text{atm}$

(b) To calculate the pressure in kPa, we employ the conversion factor between atmospheres and kPa:

$$1.049 \text{ atm} \left(\frac{101.3 \text{ kPa}}{1 \text{ atm}} \right) = 106.3 \text{ kPa}$$

Check The calculated pressure is a bit more than 1 atm, which is about 101 kPa. This makes sense because we anticipated that the pressure in the flask would be greater than the atmospheric pressure (764.7 torr = 1.01 atm) acting on the manometer.

Practice Exercise 1

If the gas inside the flask in the above exercise is cooled so that its pressure is reduced to a value of 715.7 torr, what will be the height of the mercury in the open ended arm? (Hint: The sum of the heights in both arms must remain constant regardless of the change in pressure.)
(a) 49.0 mm, (b) 95.6 mm, (c) 144.6 mm, (d) 120.1 mm.

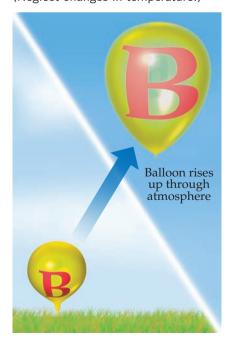

Practice Exercise 2

If the pressure of the gas inside the flask were increased and the height of the column in the open ended arm went up by 5.0 mm, what would be the new pressure of the gas in the flask, in torr?

GO FIGURE

Does atmospheric pressure increase or decrease as altitude increases? (Neglect changes in temperature.)

▲ Figure 10.4 As a balloon rises in the atmosphere, its volume increases.

10.3 | The Gas Laws

Four variables are needed to define the physical condition, or *state*, of a gas: temperature, pressure, volume, and amount of gas, usually expressed as number of moles. The equations that express the relationships among these four variables are known as the *gas laws*. Because volume is easily measured, the first gas laws to be studied expressed the effect of one of the variables on volume, with the remaining two variables held constant.

The Pressure-Volume Relationship: Boyle's Law

An inflated weather balloon released at the Earth's surface expands as it rises (◀ Figure 10.4) because the pressure of the atmosphere decreases with increasing elevation. Thus, for our first pressure–volume relationship we can use our experience with balloons to say that gas volume increases as the pressure exerted on the gas decreases.

British chemist Robert Boyle (1627–1691) first investigated the relationship between the pressure of a gas and its volume, using a J-shaped tube like that shown in Figure 10.5. In the tube on the left, a quantity of gas is trapped above a column of mercury. Boyle surmised that the pressure on the gas could be changed by adding mercury to the tube. He found that the volume of the gas decreased as the pressure increased. He learned, for example, that doubling the pressure will decrease gas volume to half its original value.

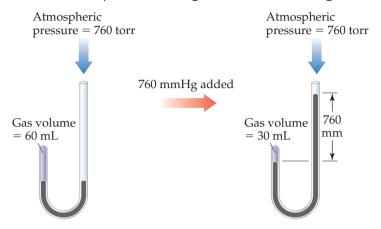

Boyle's law, which summarizes these observations, states that *the volume of a fixed quantity of gas maintained at constant temperature is inversely proportional to the pressure*. When two measurements are inversely proportional, one gets smaller as the other gets larger. Boyle's law can be expressed mathematically as

$$V = \text{constant} \times \frac{1}{P} \quad \text{or} \quad PV = \text{constant}$$
 [10.2]

The value of the constant depends on temperature and on the amount of gas in the sample.

A GO FIGURE

What is the total pressure on the gas after the 760 mm Hg has been added?

▲ Figure 10.5 Boyle's experiment relating pressure and volume for a gas.

The graph of V versus P in ∇ Figure 10.6 shows the curve obtained for a given quantity of gas at a fixed temperature. A linear relationship is obtained when V is plotted versus 1/P as shown on the right in Figure 10.6.

Boyle's law occupies a special place in the history of science because Boyle was the first to carry out experiments in which one variable was systematically changed to determine the effect on another variable. The data from the experiments were then employed to establish an empirical relationship—a "law."

We apply Boyle's law every time we breathe. The rib cage, which can expand and contract, and the diaphragm, a muscle beneath the lungs, govern the volume of the lungs. Inhalation occurs when the rib cage expands and the diaphragm moves downward. Both actions increase the volume of the lungs, thus decreasing the gas pressure inside the lungs. Atmospheric pressure then forces air into the lungs until the pressure in the lungs equals atmospheric pressure. Exhalation reverses the process—the rib cage contracts and the diaphragm moves up, decreasing the volume of the lungs. Air is forced out of the lungs by the resulting increase in pressure.

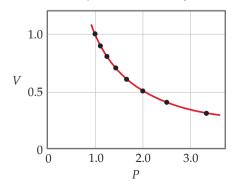

Give It Some Thought

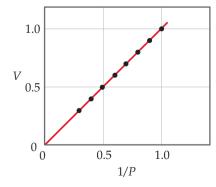

What happens to the pressure of a gas in a closed container if you double its volume while its temperature is held constant?

GO FIGURE

What would a plot of P versus 1/V look like for a fixed quantity of gas at a fixed temperature?

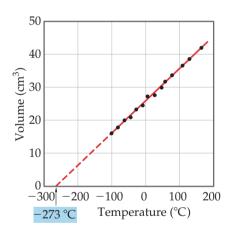

▲ Figure 10.6 Boyle's Law. For a fixed quantity of gas at constant temperature, the volume of the gas is inversely proportional to its pressure.

▲ Figure 10.7 The effect of temperature on volume.

▲ Figure 10.8 Charles's Law. For a fixed quantity of gas at constant pressure, the volume of the gas is proportional to its temperature.

The Temperature–Volume Relationship: Charles's Law

As **Figure 10.7** illustrates, the volume of an inflated balloon increases when the temperature of the gas inside the balloon increases and decreases when the temperature of the gas decreases.

The relationship between gas volume and temperature—volume increases as temperature increases and decreases as temperature decreases—was discovered in 1787 by French scientist Jacques Charles (1746–1823). Some typical volume–temperature data are shown in ∇ Figure 10.8. Notice that the extrapolated (dashed) line passes through -273 °C. Note also that the gas is predicted to have zero volume at this temperature. This condition is never realized, however, because all gases liquefy or solidify before reaching this temperature.

In 1848, William Thomson (1824–1907), a British physicist whose title was Lord Kelvin, proposed an absolute-temperature scale, now known as the Kelvin scale. On this scale, 0 K, called absolute zero, equals $-273.15\,^{\circ}$ C. ∞ (Section 1.4) In terms of the Kelvin scale, **Charles's law** states: The volume of a fixed amount of gas maintained at constant pressure is directly proportional to its absolute temperature. Thus, doubling the absolute temperature causes the gas volume to double. Mathematically, Charles's law takes the form

$$V = \text{constant} \times T \quad \text{or} \quad \frac{V}{T} = \text{constant}$$
 [10.3]

with the value of the constant depending on the pressure and on the amount of gas.

Give It Some Thought

Does the volume of a fixed quantity of gas decrease to half its original value when the temperature is lowered from $100\,^{\circ}$ C to $50\,^{\circ}$ C?

The Quantity–Volume Relationship: Avogadro's Law

The relationship between the quantity of a gas and its volume follows from the work of Joseph Louis Gay-Lussac (1778–1823) and Amedeo Avogadro (1776–1856).

Gay-Lussac was one of those extraordinary figures in the history of science who could truly be called an adventurer. In 1804, he ascended to 23,000 ft in a hot-air balloon—an exploit that held the altitude record for several decades. To better control the balloon, Gay-Lussac studied the properties of gases. In 1808, he observed the *law of combining volumes*: At a given pressure and temperature, the volumes of gases that react with one another are in the ratios of small whole numbers. For example, two volumes of hydrogen gas react with one volume of oxygen gas to form two volumes of water vapor. ∞ (Section 3.1)

Three years later, Amedeo Avogadro interpreted Gay-Lussac's observation by proposing what is now known as **Avogadro's hypothesis**: *Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules*. For example, 22.4 L of any gas at 0 °C and 1 atm contain 6.02×10^{23} gas molecules (that is, 1 mol), as depicted in **Figure 10.9**.

Avogadro's law follows from Avogadro's hypothesis: *The volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas.* That is,

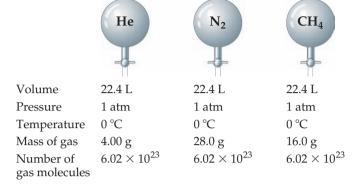

$$V = \text{constant} \times n \text{ or } \frac{V}{n} = \text{constant}$$
 [10.4]

where *n* is number of moles. Thus, for instance, doubling the number of moles of gas causes the volume to double if *T* and *P* remain constant.

GO FIGURE

How many moles of gas are in each vessel?

▲ Figure 10.9 Avogadro's hypothesis. At the same volume, pressure, and temperature, samples of different gases have the same number of molecules but different masses.

SAMPLE

EXERCISE 10.3 Evaluating the Effects of Changes in P, V, n, and T on a Gas

Suppose we have a gas confined to a cylinder with a movable piston that is sealed so there are no leaks. (Sections 5.2, 5.3) How will each of the following changes affect (i) the pressure of the gas, (ii) the number of moles of gas in the cylinder, (iii) the average distance between molecules: (a) Heating the gas while maintaining a constant pressure; (b) Reducing the volume while maintaining a constant temperature; (c) Injecting additional gas while keeping the temperature and volume constant.

SOLUTION

Analyze We need to think how each change affects (1) the pressure of the gas, (2) the number of moles of gas in the cylinder, and (3) the average distance between molecules.

Plan We can use the gas laws to evaluate the changes in pressure. The number of moles of gas in the cylinder will not change unless gas is either added or removed. Assessing the average distance between molecules is not quite as straightforward. For a given number of gas molecules, the average distance between molecules increases as the volume increases. Conversely, for constant volume, the average distance between molecules decreases as the number of moles increases. Thus the average distance between molecules will be proportional to V/n.

Solve

- (a) Because it is stipulated that the pressure remains constant, pressure is not a variable in this problem, and the total number of moles of gas will also remain constant. We know from Charles's law, however, that heating the gas while maintaining constant pressure will cause the piston to move and the volume to increase. Thus, the distance between molecules will increase.
- (b) The reduction in volume causes the pressure to increase (Boyle's law). Compressing the gas into a smaller volume does not change the total number of gas molecules; thus, the total number of moles remains the same. The average distance between molecules, however, must decrease because of the smaller volume.
- (c) Injecting more gas into the cylinder means that more molecules are present and there will be an increase in the number of moles of gas in the cylinder. Because we have added more molecules while keeping the volume constant the average distance between molecules must decrease. Avogadro's law tells us that the volume of the cylinder should have increased when we added more gas, provided the pressure and temperature were held constant. Here the volume is held constant, as is the temperature, which means the pressure must change. Knowing from Boyle's law that there is an inverse relationship between volume and pressure (PV = constant), we conclude that if the volume does not increase on injecting more gas the pressure must increase.

Practice Exercise 1

A helium balloon is filled to a volume of 5.60 liters at 25 °C. What will the volume of the balloon become if it is put into liquid nitrogen to lower the temperature of the helium to 77 K?

(a) 17 L

(b) 22 L

(c) 1.4 L (d) 0.046 L

(e) 3.7 L

Practice Exercise 2

An oxygen cylinder used in a hospital contains 35.4 L of oxygen gas at a pressure of 149.6 atm. How much volume would the oxygen occupy if it were transferred to a container that maintained a pressure of 1.00 atm if the temperature remains constant?

10.4 | The Ideal-Gas Equation

All three laws we just examined were obtained by holding two of the four variables P, V, T, and n constant and seeing how the remaining two variables affect each other. We can express each law as a proportionality relationship. Using the symbol \propto for "is proportional to," we have

Boyle's law:
$$V \propto \frac{1}{P}$$
 (constant n, T)

Charle's law:
$$V \propto T$$
 (constant n, P)

Avogadro's law:
$$V \propto n$$
 (constant P, T)

We can combine these relationships into a general gas law:

$$V \propto \frac{nT}{P}$$

and if we call the proportionality constant *R*, we obtain an equality:

$$V = R\left(\frac{nT}{P}\right)$$

which we can rearrange to

$$PV = nRT ag{10.5}$$

which is the **ideal-gas equation** (also called the **ideal-gas law**). An **ideal gas** is a hypothetical gas whose pressure, volume, and temperature relationships are described completely by the ideal-gas equation.

In deriving the ideal-gas equation, we assume (a) that the molecules of an ideal gas do not interact with one another and (b) that the combined volume of the molecules is much smaller than the volume the gas occupies; for this reason, we consider the molecules as taking up no space in the container. In many cases, the small error introduced by these assumptions is acceptable. If more accurate calculations are needed, we can correct for the assumptions if we know something about the attraction molecules have for one another and the size of the molecules.

The term R in the ideal-gas equation is the **gas constant**. The value and units of R depend on the units of P, V, n, and T. The value for T in the ideal-gas equation must always be the absolute temperature (in kelvins instead of degrees Celsius). The quantity of gas, n, is normally expressed in moles. The units chosen for pressure and volume are most often atmospheres and liters, respectively. However, other units can be used. In countries other than the United States, the pascal is the most commonly used unit for pressure. \P Table 10.2 shows the numerical value for R in various units. In working with the ideal-gas equation, you must choose the form of R in which the units agree with the units of P, V, n, and T given in the problem. In this chapter we will most often use R = 0.08206 L-atm/mol-K because pressure is most often given in atmospheres.

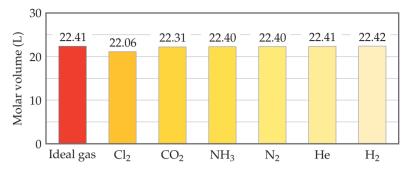

Table 10.2 Numerical Values of the Gas Constant R in Various Units

Units	Numerical Value
L-atm/mol-K	0.08206
J/mol-K*	8.314
cal/mol-K	1.987
m³-Pa/mol-K*	8.314
L-torr/mol-K	62.36

^{*}SI unit

A GO FIGURE

Which gas deviates most from ideal behavior?

▲ Figure 10.10 Comparison of molar volumes at STP.

Suppose we have 1.000 mol of an ideal gas at 1.000 atm and 0.00 °C (273.15 K). According to the ideal-gas equation, the volume of the gas is

$$V = \frac{nRT}{P} = \frac{(1.000 \text{ mol})(0.08206 \text{ L-atm/mol-K})(273.15 \text{ K})}{1.000 \text{ atm}} = 22.41 \text{ L}$$

The conditions 0 °C and 1 atm are referred to as standard temperature and pressure (STP). The volume occupied by 1 mol of ideal gas at STP, 22.41 L, is known as the molar volume of an ideal gas at STP.

Give It Some Thought

If 1.00 mol of an ideal gas at STP were confined to a cube, what would be the length in cm of an edge of this cube?

The ideal-gas equation accounts adequately for the properties of most gases under a variety of circumstances. The equation is not exactly correct, however, for any real gas. Thus, the measured volume for given values of *P*, *n*, and *T* might differ from the volume calculated from PV = nRT (\triangle Figure 10.10). Although real gases do not always behave ideally, their behavior differs so little from ideal behavior that we can ignore any deviations for all but the most accurate work.

SAMPLE

EXERCISE 10.4 Using the Ideal-Gas Equation

Calcium carbonate, $CaCO_3(s)$, the principal compound in limestone, decomposes upon heating to CaO(s) and $CO_2(g)$. A sample of $CaCO_3$ is decomposed, and the carbon dioxide is collected in a 250-mL flask. After decomposition is complete, the gas has a pressure of 1.3 atm at a temperature of 31 °C. How many moles of CO₂ gas were generated?

SOLUTION

Analyze We are given the volume (250 mL), pressure (1.3 atm), and temperature (31 °C) of a sample of CO₂ gas and asked to calculate the number of moles of CO₂ in the sample.

Plan Because we are given V, P, and T, we can solve the ideal-gas equation for the unknown quantity, n.

Solve In analyzing and solving gas law problems, it is helpful to tabulate the information given in the problems and then to convert the values to units that are consistent with those for R(0.08206 L-atm/mol-K). In this case, the given values are

$$V = 250 \text{ mL} = 0.250 \text{ L}$$

 $P = 1.3 \text{ atm}$
 $T = 31 \,^{\circ}\text{C} = (31 + 273) \text{ K} = 304 \text{ K}$

Remember: Absolute temperature must always be used when the ideal-gas equation is solved.

We now rearrange the ideal-gas equation (Equation 10.5) to solve for n

$$n = \frac{PV}{RT}$$

$$n = \frac{(1.3 \text{ atm})(0.250 \text{ L})}{(0.08206 \text{ L-atm/mol-K})(304 \text{ K})} = 0.013 \text{ mol CO}_2$$

Check Appropriate units cancel, thus ensuring that we have properly rearranged the ideal-gas equation and have converted to the correct units.

Practice Exercise 1

The Goodyear blimp contains 5.74×10^6 L of helium at 25 °C and 1.00 atm. What is the mass in grams of the helium inside the blimp? (a) 2.30×10^7 g, (b) 2.80×10^6 g, (c) 1.12×10^7 g, (d) 2.34×10^5 g, (e) 9.39×10^5 g.

Practice Exercise 2

Tennis balls are usually filled with either air or N_2 gas to a pressure above atmospheric pressure to increase their bounce. If a tennis ball has a volume of 144 cm³ and contains 0.33 g of N_2 gas, what is the pressure inside the ball at 24 °C?

Strategies in Chemistry

Calculations Involving Many Variables

In this chapter, we encounter a variety of problems based on the idealgas equation, which contains four variables—P, V, n, and T—and one constant, R. Depending on the type of problem, we might need to solve for any of the four variables.

To extract the necessary information from problems involving more than one variable, we suggest the following steps:

- Tabulate information. Read the problems carefully to determine which variable is the unknown and which variables have numeric values given. Every time you encounter a numerical value, jot it down. In many cases, constructing a table of the given information will be useful.
- **2. Convert to consistent units.** Make certain that quantities are converted to the proper units. In using the ideal-gas equation, for example, we usually use the value of *R* that has units of L-atm/mol-K. If you are given a pressure in torr, you will need to convert it to atmospheres before using this value of *R* in your calculations.
- 3. If a single equation relates the variables, solve the equation for the unknown. For the ideal-gas equation, these algebraic rearrangements will all be used at one time or another:

$$P = \frac{nRT}{V}$$
, $V = \frac{nRT}{P}$, $n = \frac{PV}{RT}$, $T = \frac{PV}{nR}$

4. Use dimensional analysis. Carry the units through your calculation. Using dimensional analysis enables you to check that you

have solved an equation correctly. If the units in the equation cancel to give the units of the desired variable, you have probably used the equation correctly.

Sometimes you will not be given explicit values for several variables, making it look like a problem that cannot be solved. In these cases, however, you should look for information that can be used to determine the needed variables. For example, suppose you are using the ideal-gas equation to calculate a pressure in a problem that gives a value for T but not for n or V. However, the problem states that "the sample contains 0.15 mol of gas per liter." You can turn this statement into the expression

$$\frac{n}{V} = 0.15 \,\text{mol/L}$$

Solving the ideal-gas equation for pressure yields

$$P = \frac{nRT}{V} = \left(\frac{n}{V}\right)RT$$

Thus, we can solve the equation even though we are not given values for n and V.

As we have continuously stressed, the most important thing you can do to become proficient at solving chemistry problems is to do the practice exercises and end-of-chapter exercises. By using systematic procedures, such as those described here, you should be able to minimize difficulties in solving problems involving many variables.

Relating the Ideal-Gas Equation and the Gas Laws

The gas laws we discussed in Section 10.3 are special cases of the ideal-gas equation. For example, when n and T are held constant, the product nRT contains three constants and so must itself be a constant:

$$PV = nRT = \text{constant}$$
 or $PV = \text{constant}$ [10.6]

Note that this rearrangement gives Boyle's law. We see that if *n* and *T* are constant, the values of *P* and *V* can change, but the product *PV* must remain constant.

We can use Boyle's law to determine how the volume of a gas changes when its pressure changes. For example, if a cylinder fitted with a movable piston holds 50.0 L of O_2 gas at 18.5 atm and $21 \,^{\circ}\text{C}$, what volume will the gas occupy if the temperature is

maintained at 21 °C while the pressure is reduced to 1.00 atm? Because the product *PV* is a constant when a gas is held at constant *n* and *T*, we know that

$$P_1 V_1 = P_2 V_2 ag{10.7}$$

where P_1 and V_1 are initial values and P_2 and V_2 are final values. Dividing both sides of this equation by P_2 gives the final volume, V_2 :

$$V_2 = V_1 \times \frac{P_1}{P_2} = (50.0 \text{ L}) \left(\frac{18.5 \text{ atm}}{1.00 \text{ atm}} \right) = 925 \text{ L}$$

The answer is reasonable because a gas expands as its pressure decreases.

In a similar way, we can start with the ideal-gas equation and derive relationships between any other two variables, V and T (Charles's law), n and V (Avogadro's law), or P and T.

SAMPLE EXERCISE 10.5

Calculating the Effect of Temperature Changes on Pressure

The gas pressure in an aerosol can is 1.5 atm at 25 $^{\circ}$ C. Assuming that the gas obeys the ideal-gas equation, what is the pressure when the can is heated to 450 $^{\circ}$ C?

SOLUTION

Analyze We are given the initial pressure (1.5 atm) and temperature (25 $^{\circ}$ C) of the gas and asked for the pressure at a higher temperature (450 $^{\circ}$ C).

Plan The volume and number of moles of gas do not change, so we must use a relationship connecting pressure and temperature. Converting temperature to the Kelvin scale and tabulating the given information, we have

	P	T
Initial	1.5 atm	298 K
Final	P_2	723 K

Solve To determine how P and T are related, we start with the ideal-gas equation and isolate the quantities that do not change (n, V, and R) on one side and the variables (P and T) on the other side.

$$\frac{P}{T} = \frac{nR}{V} = \text{constant}$$

Because the quotient P/T is a constant, we can write

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

(where the subscripts 1 and 2 represent the initial and final states, respectively). Rearranging to solve for P_2 and substituting the given data give

$$P_2 = (1.5 \text{ atm}) \left(\frac{723 \text{ K}}{298 \text{ K}} \right) = 3.6 \text{ atm}$$

Check This answer is intuitively reasonable—increasing the temperature of a gas increases its pressure.

Comment It is evident from this example why aerosol cans carry a warning not to incinerate.

Practice Exercise 1

If you fill your car tire to a pressure of 32 psi (pounds per square inch) on a hot summer day when the temperature is $35 \,^{\circ}\text{C}$ (95 $^{\circ}\text{F}$), what is the pressure (in psi) on a cold winter day when the temperature is $-15 \,^{\circ}\text{C}$ (5 $^{\circ}\text{F}$)? Assume no gas leaks out between measurements and the volume of the tire does not change. (a) 38 psi, (b) 27 psi, (c) $-13.7 \,\text{psi}$, (d) 1.8 psi, (e) 13.7 psi.

Practice Exercise 2

The pressure in a natural-gas tank is maintained at 2.20 atm. On a day when the temperature is -15 °C, the volume of gas in the tank is 3.25×10^3 m³. What is the volume of the same quantity of gas on a day when the temperature is 31 °C?

We are often faced with the situation in which P, V, and T all change for a fixed number of moles of gas. Because n is constant in this situation, the ideal-gas equation gives

$$\frac{PV}{T} = nR = \text{constant}$$

If we represent the initial and final conditions by subscripts 1 and 2, respectively, we can write

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2} \tag{10.8}$$

This equation is often called the *combined gas law*.

SAMPLE

EXERCISE 10.6 Using the Combined Gas Law

An inflated balloon has a volume of 6.0 L at sea level (1.0 atm) and is allowed to ascend until the pressure is 0.45 atm. During ascent, the temperature of the gas falls from 22 °C to -21 °C. Calculate the volume of the balloon at its final altitude.

SOLUTION

Analyze We need to determine a new volume for a gas sample when both pressure and temperature change.

Plan Let's again proceed by converting temperatures to kelvins and tabulating our information.

	P	V	T
Initial	1.0 atm	6.0 L	295 K
Final	0.45 atm	V_2	252 K

Because n is constant, we can use Equation 10.8.

Solve Rearranging Equation 10.8 to solve for V_2 gives

$$V_2 = V_1 \times \frac{P_1}{P_2} \times \frac{T_2}{T_1} = (6.0 \text{ L}) \left(\frac{1.0 \text{ atm}}{0.45 \text{ atm}}\right) \left(\frac{252 \text{ K}}{295 \text{ K}}\right) = 11 \text{ L}$$

Check The result appears reasonable. Notice that the calculation involves multiplying the initial volume by a ratio of pressures and a ratio of temperatures. Intuitively, we expect decreasing pressure to cause the volume to increase, while decreasing the temperature should have the opposite effect. Because the change in pressure is more dramatic than the change in temperature, we expect the effect of the pressure change to predominate in determining the final volume, as it does.

Practice Exercise 1

A gas occupies a volume of 0.75 L at 20 °C at 720 torr. What volume would the gas occupy at 41 °C and 760 torr? (a) 1.45 L, (b) 0.85 L, (c) 0.76 L, (d) 0.66 L, (e) 0.35 L.

Practice Exercise 2

A 0.50-mol sample of oxygen gas is confined at 0 °C and 1.0 atm in a cylinder with a movable piston. The piston compresses the gas so that the final volume is half the initial volume and the final pressure is 2.2 atm. What is the final temperature of the gas in degrees Celsius?

10.5 | Further Applications of the Ideal-Gas Equation

In this section, we use the ideal-gas equation first to define the relationship between the density of a gas and its molar mass, and then to calculate the volumes of gases formed or consumed in chemical reactions.

Gas Densities and Molar Mass

Recall that density has units of mass per unit volume (d = m/V). ∞ (Section 1.4) We can arrange the ideal-gas equation to obtain similar units of moles per unit volume:

$$\frac{n}{V} = \frac{P}{RT}$$

If we multiply both sides of this equation by the molar mass, \mathcal{M} , which is the number of grams in 1 mol of a substance ∞ (Section 3.4), we obtain

$$\frac{n\,\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT} \tag{10.9}$$

The term on the left equals the density in grams per liter:

$$\frac{moles}{liter} \times \frac{grams}{mole} = \frac{grams}{liter}$$

Thus, the density of the gas is also given by the expression on the right in Equation 10.9:

$$d = \frac{n\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT}$$
 [10.10]

This equation tells us that the density of a gas depends on its pressure, molar mass, and temperature. The higher the molar mass and pressure, the denser the gas. The higher the temperature, the less dense the gas. Although gases form homogeneous mixtures, a less dense gas will lie above a denser gas in the absence of mixing. For example, CO_2 has a higher molar mass than N_2 or O_2 and is therefore denser than air. For this reason, CO_2 released from a CO_2 fire extinguisher blankets a fire, preventing O_2 from reaching the combustible material. "Dry ice," which is solid CO_2 , converts directly to CO_2 gas at room temperature, and the resulting "fog" (which is actually condensed water droplets cooled by the CO_2) flows downhill in air (\triangleright Figure 10.11).

When we have equal molar masses of two gases at the same pressure but different temperatures, the hotter gas is less dense than the cooler one, so the hotter gas rises. The difference between the densities of hot and cold air is responsible for the lift of hotair balloons. It is also responsible for many phenomena in weather, such as the formation of large thunderheads during thunderstorms.

▲ Figure 10.11 Carbon dioxide gas flows downward because it is denser than air.

Give It Some Thought

Is water vapor more or less dense than N_2 under the same conditions of temperature and pressure?

SAMPLE EXERCISE 10.7 Calculating Gas Density

What is the density of carbon tetrachloride vapor at 714 torr and 125 °C?

SOLUTION

Analyze We are asked to calculate the density of a gas given its name, its pressure, and its temperature. From the name, we can write the chemical formula of the substance and determine its molar mass.

Plan We can use Equation 10.10 to calculate the density. Before we can do that, however, we must convert the given quantities to the appropriate units, degrees Celsius to kelvins and pressure to atmospheres. We must also calculate the molar mass of CCl_4 .

Solve The absolute temperature is 125 + 273 = 398 K. The pressure is (714 torr) (1 atm/760 torr) = 0.939 atm. The molar mass of CCl₄ is 12.01 + (4) (35.45) = 153.8 g/mol. Therefore,

$$d = \frac{(0.939 \text{ atm})(153.8 \text{ g/mol})}{(0.08206 \text{ L-atm/mol-K})(398 \text{ K})} = 4.42 \text{ g/L}$$

Check If we divide molar mass (g/mol) by density (g/L), we end up with L/mol. The numerical value is roughly 154/4.4 = 35, which is in the right ballpark for the molar volume of a gas heated to 125 °C at near atmospheric pressure. We may thus conclude our answer is reasonable.

Practice Exercise 1

What is the density of methane, CH_4 , in a vessel where the pressure is 910 torr and the temperature is 255 K? (a) 0.92 g/L, (b) 697 g/L, (c) 0.057 g/L, (d) 16 g/L, (e) 0.72 g/L.

Practice Exercise 2

The mean molar mass of the atmosphere at the surface of Titan, Saturn's largest moon, is $28.6 \, \text{g/mol}$. The surface temperature is 95 K, and the pressure is 1.6 atm. Assuming ideal behavior, calculate the density of Titan's atmosphere.

Equation 10.10 can be rearranged to solve for the molar mass of a gas:

$$\mathcal{M} = \frac{dRT}{P}$$
 [10.11]

Thus, we can use the experimentally measured density of a gas to determine the molar mass of the gas molecules, as shown in Sample Exercise 10.8.

SAMPLE EXERCISE 10.8 Calculating the Molar Mass of a Gas

A large evacuated flask initially has a mass of 134.567 g. When the flask is filled with a gas of unknown molar mass to a pressure of 735 torr at 31 °C, its mass is 137.456 g. When the flask is evacuated again and then filled with water at 31 °C, its mass is 1067.9 g. (The density of water at this temperature is 0.997 g/mL.) Assuming the ideal-gas equation applies, calculate the molar mass of the gas.

SOLUTION

Analyze We are given the temperature (31 °C) and pressure (735 torr) for a gas, together with information to determine its volume and mass, and we are asked to calculate its molar mass.

Plan The data obtained when the flask is filled with water can be used to calculate the volume of the container. The mass of the empty flask and of the flask when filled with gas can be used to calculate the mass of the gas. From these quantities we calculate the gas density and then apply Equation 10.11 to calculate the molar mass of the gas.

Solve The gas volume equals the volume of water the flask can hold, calculated from the mass and density of the water. The mass of the water is the difference between the masses of the full and evacuated flask:

$$1067.9 \,\mathrm{g} \,-\, 134.567 \,\mathrm{g} \,=\, 933.3 \,\mathrm{g}$$

Rearranging the equation for density (d = m/V), we have

$$V = \frac{m}{d} = \frac{(933.3 \,\mathrm{g})}{(0.997 \,\mathrm{g/mL})} = 936 \,\mathrm{mL} = 0.936 \,\mathrm{L}$$

The gas mass is the difference between the mass of the flask filled with gas and the mass of the evacuated flask:

$$137.456 \,\mathrm{g} - 134.567 \,\mathrm{g} = 2.889 \,\mathrm{g}$$

Knowing the mass of the gas (2.889 g) and its volume (0.936 L), we can calculate the density of the gas:

$$d = 2.889 \,\mathrm{g}/0.936 \,\mathrm{L} = 3.09 \,\mathrm{g/L}$$

After converting pressure to atmospheres and temperature to kelvins, we can use Equation 10.11 to calculate the molar mass:

$$\mathcal{M} = \frac{dRT}{P}$$
=\frac{(3.09 \text{ g/L})(0.08206 \text{ L-atm/mol-K})(304 \text{ K})}{(0.967 \text{ atm})}
= 79.7 \text{ g/mol}

Check The units work out appropriately, and the value of molar mass obtained is reasonable for a substance that is gaseous near room temperature.

Practice Exercise 1

What is the molar mass of an unknown hydrocarbon whose density is measured to be 1.97 g/L at STP? (a) 4.04 g/mol, (b) 30.7 g/mol, (c) 44.1 g/mol, (d) 48.2 g/mol.

Practice Exercise 2

Calculate the average molar mass of dry air if it has a density of 1.17 g/L at 21 $^{\circ}\text{C}$ and 740.0 torr.

Volumes of Gases in Chemical Reactions

We are often concerned with knowing the identity and/or quantity of a gas involved in a chemical reaction. Thus, it is useful to be able to calculate the volumes of gases consumed or produced in reactions. Such calculations are based on the mole concept and balanced chemical equations. ∞ (Section 3.6) The coefficients in a balanced chemical equation tell us the relative amounts (in moles) of reactants and products in a reaction. The ideal-gas equation relates the number of moles of a gas to P, V, and T.

SAMPLE EXERCISE 10.9 Relating Gas Variables and Reaction Stoichiometry

Automobile air bags are inflated by nitrogen gas generated by the rapid decomposition of sodium azide, NaN_3 :

$$2 \text{ NaN}_3(s) \longrightarrow 2 \text{ Na}(s) + 3 \text{ N}_2(g)$$

If an air bag has a volume of 36 L and is to be filled with nitrogen gas at 1.15 atm and 26 °C, how many grams of NaN₃ must be decomposed?

SOLUTION

Analyze This is a multistep problem. We are given the volume, pressure, and temperature of the N_2 gas and the chemical equation for the reaction by which the N_2 is generated. We must use this information to calculate the number of grams of NaN_3 needed to obtain the necessary N_3 .

Plan We need to use the gas data (P, V, and T) and the ideal-gas equation to calculate the number of moles of N_2 gas that should be formed for the air bag to operate correctly. We can then use the balanced equation to determine the number of moles of NaN_3 needed. Finally, we can convert moles of NaN_3 to grams.

Solve The number of moles of N_2 is determined using the ideal-gas equation:

$$n = \frac{PV}{RT} = \frac{(1.15 \text{ atm})(36 \text{ L})}{(0.08206 \text{ L-atm/mol-K})(299 \text{ K})} = 1.69 \text{ mol N}_2$$

We use the coefficients in the balanced equation to calculate the number of moles of NaN_3 :

$$(1.69 \ mol \ N_2) \bigg(\frac{2 \ mol \ NaN_3}{3 \ mol \ N_2} \bigg) = \ 1.12 \ mol \ NaN_3$$

Finally, using the molar mass of NaN₃, we convert moles of NaN₃ to grams:

$$(1.12 \text{ mol NaN}_3) \left(\frac{65.0 \text{ g NaN}_3}{1 \text{ mol NaN}_3} \right) = 73 \text{ g NaN}_3$$

Check The units cancel properly at each step in the calculation, leaving us with the correct units in the answer, $g \text{ NaN}_3$.

Practice Exercise 1

When silver oxide is heated, it decomposes according to the reaction:

$$2 \operatorname{Ag_2O}(s) \xrightarrow{\Delta} 4 \operatorname{Ag}(s) + \operatorname{O_2}(g)$$

If 5.76 g of Ag_2O is heated and the O_2 gas produced by the reaction is collected in an evacuated flask, what is the pressure of the O_2 gas if the volume of the flask is 0.65 L and the gas temperature is 25 °C? (a) 0.94 atm, (b) 0.039 atm, (c) 0.012 atm, (d) 0.47 atm, (e) 3.2 atm.

Practice Exercise 2

In the first step of the industrial process for making nitric acid, ammonia reacts with oxygen in the presence of a suitable catalyst to form nitric oxide and water vapor:

$$4 \text{ NH}_3(g) + 5 \text{ O}_2(g) \longrightarrow 4 \text{ NO}(g) + 6 \text{ H}_2\text{O}(g)$$

How many liters of $NH_3(g)$ at 850 °C and 5.00 atm are required to react with 1.00 mol of $O_2(g)$ in this reaction?

10.6 | Gas Mixtures and Partial Pressures

Thus far we have considered mainly pure gases—those that consist of only one substance in the gaseous state. How do we deal with mixtures of two or more different gases? While studying the properties of air, John Dalton (Section 2.1) made an important observation: The total pressure of a mixture of gases equals the sum of the pressures that each would exert if it were present alone. The pressure exerted by a particular component of a mixture of gases is called the partial pressure of that component. Dalton's observation is known as Dalton's law of partial pressures.

If we let P_t be the total pressure of a mixture of gases and P_1 , P_2 , P_3 , and so forth be the partial pressures of the individual gases, we can write Dalton's law of partial pressures as

$$P_t = P_1 + P_2 + P_3 + \dots$$
 [10.12]

This equation implies that each gas behaves independently of the others, as we can see by the following analysis. Let n_1 , n_2 , n_3 , and so forth be the number of moles of each of the gases in the mixture and n_t be the total number of moles of gas. If each gas obeys the ideal-gas equation, we can write

$$P_1 = n_1 \left(\frac{RT}{V}\right)$$
; $P_2 = n_2 \left(\frac{RT}{V}\right)$; $P_3 = n_3 \left(\frac{RT}{V}\right)$; and so forth

All of the gases in a container must occupy the same volume and will come to the same temperature in a relatively short period of time. Using these facts to simplify Equation 10.12, we obtain

$$P_t = (n_1 + n_2 + n_3 + \dots) \left(\frac{RT}{V}\right) = n_t \left(\frac{RT}{V}\right)$$
 [10.13]

That is, at constant temperature and constant volume the total pressure of a gas sample is determined by the total number of moles of gas present, whether that total represents just one gas or a mixture of gases.

Give It Some Thought

How is the partial pressure exerted by N_2 gas affected when some O_2 is introduced into a container if the temperature and volume remain constant? How is the total pressure affected?

SAMPLE EXERCISE 10.10 Applying Dalton's Law of Partial Pressures

A mixture of 6.00 g of $O_2(g)$ and 9.00 g of $CH_4(g)$ is placed in a 15.0-L vessel at 0 °C. What is the partial pressure of each gas, and what is the total pressure in the vessel?

SOLUTION

Analyze We need to calculate the pressure for two gases in the same volume and at the same temperature.

Plan Because each gas behaves independently, we can use the ideal-gas equation to calculate the pressure each would exert if the other were not present. Per Dalton's law, the total pressure is the sum of these two partial pressures.

Solve We first convert the mass of each gas to moles:

$$n_{\text{O}_2} = (6.00 \text{ g O}_2) \left(\frac{1 \text{ mol O}_2}{32.0 \text{ g O}_2} \right) = 0.188 \text{ mol O}_2$$

$$n_{\text{CH}_4} = (9.00 \text{ g CH}_4) \left(\frac{1 \text{ mol CH}_4}{16.0 \text{ g CH}_4} \right) = 0.563 \text{ mol CH}_4$$

We use the ideal-gas equation to calculate the partial pressure of each gas:

$$P_{\rm O_2} = \frac{n_{\rm O_2}RT}{V} = \frac{(0.188 \, {\rm mol})(0.08206 \, {\rm L-atm/mol-K}) \, (273 \, {\rm K})}{15.0 \, {\rm L}} = 0.281 \, {\rm atm}$$

$$P_{\text{CH}_4} = \frac{n_{\text{CH}_4}RT}{V} = \frac{(0.563 \text{ mol})(0.08206 \text{ L-atm/mol-K})(273 \text{ K})}{15.0 \text{ L}} = 0.841 \text{ atm}$$

According to Dalton's law of partial pressures (Equation 10.12), the total pressure in the vessel is the sum of the partial pressures:

$$P_t = P_{O_2} + P_{CH_4} = 0.281 \text{ atm} + 0.841 \text{ atm} = 1.122 \text{ atm}$$

Check A pressure of roughly 1 atm seems right for a mixture of about 0.2 mol O_2 and a bit more than 0.5 mol CH_4 , together in a 15-L volume, because 1 mol of an ideal gas at 1 atm pressure and 0 °C occupies about 22 L.

Practice Exercise 1

A 15-L cylinder contains 4.0 g of hydrogen and 28 g of nitrogen. If the temperature is $27 \,^{\circ}$ C what is the total pressure of the mixture? (a) 0.44 atm, (b) 1.6 atm, (c) 3.3 atm, (d) 4.9 atm, (e) 9.8 atm.

Practice Exercise 2

What is the total pressure exerted by a mixture of 2.00 g of $H_2(g)$ and 8.00 g of $N_2(g)$ at 273 K in a 10.0-L vessel?

Partial Pressures and Mole Fractions

Because each gas in a mixture behaves independently, we can relate the amount of a given gas in a mixture to its partial pressure. For an ideal gas, we can write

$$\frac{P_1}{P_t} = \frac{n_1 RT/V}{n_t RT/V} = \frac{n_1}{n_t}$$
 [10.14]

The ratio n_1/n_t is called the *mole fraction of gas 1*, which we denote X_1 . The **mole fraction**, X, is a dimensionless number that expresses the ratio of the number of moles of one component in a mixture to the total number of moles in the mixture. Thus, for gas 1 we have

$$X_1 = \frac{\text{Moles of compound 1}}{\text{Total moles}} = \frac{n_1}{n_t}$$
 [10.15]

We can combine Equations 10.14 and 10.15 to give

$$P_1 = \left(\frac{n_1}{n_t}\right) P_t = X_1 P_t$$
 [10.16]

The mole fraction of N_2 in air is 0.78—that is, 78% of the molecules in air are N_2 . This means that if the barometric pressure is 760 torr, the partial pressure of N_2 is

$$P_{N_2} = (0.78)(760 \text{ torr}) = 590 \text{ torr}$$

This result makes intuitive sense: Because N_2 makes up 78% of the mixture, it contributes 78% of the total pressure.

SAMPLE EXERCISE 10.11 Relating Mole Fractions and Partial Pressures

A study of the effects of certain gases on plant growth requires a synthetic atmosphere composed of 1.5 mol % CO_2 , 18.0 mol % O_2 , and 80.5 mol % Ar. (a) Calculate the partial pressure of O_2 in the mixture if the total pressure of the atmosphere is to be 745 torr. (b) If this atmosphere is to be held in a 121-L space at 295 K, how many moles of O_2 are needed?

SOLUTION

Analyze For (a) we need to calculate the partial pressure of O_2 given its mole percent and the total pressure of the mixture. For (b) we need to calculate the number of moles of O_2 in the mixture given its volume (121 L), temperature (745 torr), and partial pressure from part (a).

Plan We calculate the partial pressures using Equation 10.16, and then use P_{O_2} , V, and T in the ideal-gas equation to calculate the number of moles of O_2 .

Solve

(a) The mole percent is the mole fraction times 100. Therefore, the mole fraction of O_2 is 0.180. Equation 10.16 gives

$$P_{\rm O_2} = (0.180)(745 \, \text{torr}) = 134 \, \text{torr}$$

(b) Tabulating the given variables and converting to appropriate units, we have

$$P_{\rm O_2} = (134 \, {\rm torr}) \left(\frac{1 \, {\rm atm}}{760 \, {\rm torr}} \right) = 0.176 \, {\rm atm}$$
 $V = 121 \, {\rm L}$
 $n_{\rm O_2} = ?$
 $R = 0.08206 \, \frac{{\rm L-atm}}{{\rm mol-K}}$
 $T = 295 \, {\rm K}$

Solving the ideal-gas equation for n_{O_2} , we have

$$n_{\text{O}_2} = P_{\text{O}_2} \left(\frac{V}{RT}\right)$$

= $(0.176 \text{ atm}) \frac{121 \text{ L}}{(0.08206 \text{ L-atm/mol-K})(295 \text{ K})} = 0.880 \text{ mol}$

Check The units check out, and the answer seems to be the right order of magnitude.

Practice Exercise 1

A 4.0-L vessel containing N_2 at STP and a 2.0-L vessel containing H_2 at STP are connected by a valve. If the valve is opened allowing the two gases to mix, what is the mole fraction of hydrogen in the mixture? (a) 0.034, (b) 0.33, (c) 0.50, (d) 0.67, (e) 0.96.

Practice Exercise 2

From data gathered by *Voyager 1*, scientists have estimated the composition of the atmosphere of Titan, Saturn's largest moon. The pressure on the surface of Titan is 1220 torr. The atmosphere consists of 82 mol % N₂, 12 mol % Ar, and 6.0 mol % CH₄. Calculate the partial pressure of each gas.

10.7 | The Kinetic-Molecular Theory of Gases

The ideal-gas equation describes *how* gases behave but not *why* they behave as they do. Why does a gas expand when heated at constant pressure? Or why does its pressure increase when the gas is compressed at constant temperature? To understand the physical properties of gases, we need a model that helps us picture what happens to gas particles when conditions such as pressure or temperature change. Such a model, known as the **kinetic-molecular theory of gases**, was developed over a period of about 100 years, culminating in 1857 when Rudolf Clausius (1822–1888) published a complete and satisfactory form of the theory.

The kinetic-molecular theory (the theory of moving molecules) is summarized by the following statements:

- Gases consist of large numbers of molecules that are in continuous, random motion. (The word *molecule* is used here to designate the smallest particle of any gas even though some gases, such as the noble gases, consist of individual atoms. All we learn about gas behavior from the kinetic-molecular theory applies equally to atomic gases.)
- **2.** The combined volume of all the molecules of the gas is negligible relative to the total volume in which the gas is contained.
- 3. Attractive and repulsive forces between gas molecules are negligible.
- **4.** Energy can be transferred between molecules during collisions but, as long as temperature remains constant, the *average* kinetic energy of the molecules does not change with time.

5. The average kinetic energy of the molecules is proportional to the absolute temperature. At any given temperature, the molecules of all gases have the same average kinetic energy.

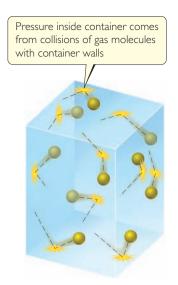

The kinetic-molecular theory explains both pressure and temperature at the molecular level. The pressure of a gas is caused by collisions of the molecules with the walls of the container (**Figure 10.12**). The magnitude of the pressure is determined by how often and how forcefully the molecules strike the walls.

The absolute temperature of a gas is a measure of the *average* kinetic energy of its molecules. If two gases are at the same temperature, their molecules have the same average kinetic energy (statement 5 of the kinetic-molecular theory). If the absolute temperature of a gas is doubled, the average kinetic energy of its molecules doubles. Thus, molecular motion increases with increasing temperature.

Distributions of Molecular Speed

Although collectively the molecules in a sample of gas have an *average* kinetic energy and hence an average speed, the individual molecules are moving at different speeds. Each molecule collides frequently with other molecules. Momentum is conserved in each collision, but one of the colliding molecules might be deflected off at high speed while the other is nearly stopped. The result is that, at any instant, the molecules in the sample have a wide range of speeds. In ▼ Figure 10.13(a), which shows the distribution of molecular speeds for nitrogen gas at 0 °C and 100 °C, we see that a larger fraction of the 100 °C molecules moves at the higher speeds. This means that the 100 °C sample has the higher average kinetic energy.

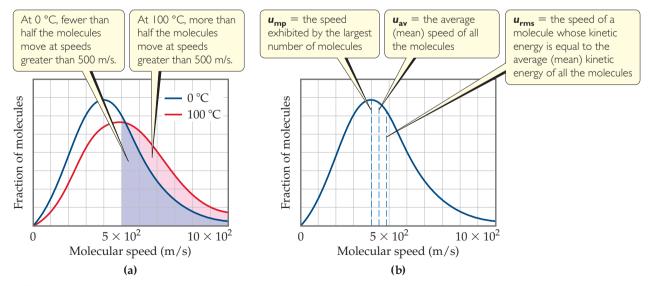

In any graph of the distribution of molecular speeds in a gas sample, the peak of the curve represents the most probable speed, $u_{\rm mp}$ [Figure 10.13(b)]. The most probable speeds in Figure 10.13(a), for instance, are $4\times10^2\,{\rm m/s}$ for the 0 °C sample and $5\times10^2\,{\rm m/s}$ for the 100 °C sample. Figure 10.13(b) also shows the **root-mean-square (rms) speed**, $u_{\rm rms}$, of the molecules. This is the speed of a molecule possessing a kinetic energy identical to the average kinetic energy of the sample. The rms speed is not quite the same as the average (mean) speed, $u_{\rm av}$. The difference between the two is

▲ Figure 10.12 The molecular origin of gas pressure.

GO FIGURE

Estimate the fraction of molecules at 100 °C with speeds less than 300 m/s.

▲ Figure 10.13 Distribution of molecular speeds for nitrogen gas. (a) The effect of temperature on molecular speed. The relative area under the curve for a range of speeds gives the relative fraction of molecules that have those speeds. (b) Position of most probable (u_{mp}) , average (u_{av}) , and root-mean-square (u_{rms}) speeds of gas molecules. The data shown here are for nitrogen gas at 0 °C.

small, however. In Figure 10.13(b), for example, the root-mean-square speed is about 4.9×10^2 m/s and the average speed is about 4.5×10^2 m/s.

If you calculate the rms speeds (as we will in Section 10.8), you will find that the rms speed is almost $6 \times 10^2 \, \text{m/s}$ for the 100 °C sample but slightly less than $5 \times 10^2 \, \text{m/s}$ for the 0 °C sample. Notice that the distribution curve broadens as we go to a higher temperature, which tells us that the range of molecular speeds increases with temperature.

The rms speed is important because the average kinetic energy of the gas molecules in a sample is equal to $\frac{1}{2}m(u_{\rm rms})^2$. ∞ (Section 5.1) Because mass does not change with temperature, the increase in the average kinetic energy $\frac{1}{2}m(u_{\rm rms})^2$ as the temperature increases implies that the rms speed of the molecules (as well as $u_{\rm av}$ and $u_{\rm mp}$) increases as temperature increases.

Give It Some Thought

Consider three gases all at 298 K: HCl, H_2 , and O_2 . List the gases in order of increasing average speed.

Application of Kinetic-Molecular Theory to the Gas Laws

The empirical observations of gas properties as expressed by the various gas laws are readily understood in terms of the kinetic-molecular theory. The following examples illustrate this point:

- 1. An increase in volume at constant temperature causes pressure to decrease. A constant temperature means that the average kinetic energy of the gas molecules remains unchanged. This means that the rms speed of the molecules remains unchanged. When the volume is increased, the molecules must move a longer distance between collisions. Consequently, there are fewer collisions per unit time with the container walls, which means the pressure decreases. Thus, kinetic-molecular theory explains Boyle's law.
- 2. A temperature increase at constant volume causes pressure to increase. An increase in temperature means an increase in the average kinetic energy of the molecules and in $u_{\rm rms}$. Because there is no change in volume, the temperature increase causes more collisions with the walls per unit time because the molecules are all moving faster. Furthermore, the momentum in each collision increases (the molecules strike the walls more forcefully). A greater number of more forceful collisions means the pressure increases, and the theory explains this increase.

SAMPLE EXERCISE 10.12 Applying the Kinetic-Molecular Theory

A sample of O_2 gas initially at STP is compressed to a smaller volume at constant temperature. What effect does this change have on (a) the average kinetic energy of the molecules, (b) their average speed, (c) the number of collisions they make with the container walls per unit time, (d) the number of collisions they make with a unit area of container wall per unit time, (e) the pressure?

SOLUTION

Analyze We need to apply the concepts of the kinetic-molecular theory of gases to a gas compressed at constant temperature.

Plan We will determine how each of the quantities in (a)–(e) is affected by the change in volume at constant temperature.

Solve (a) Because the average kinetic energy of the O_2 molecules is determined only by temperature, this energy is unchanged by the compression. (b) Because the average kinetic energy of the molecules does not change, their average speed remains constant. (c) The number of collisions with the walls per unit time increases because the molecules are moving in a smaller volume but with the same average speed as before. Under these conditions they will strike the walls of the container more frequently. (d) The number of collisions with a unit area of wall per unit time increases because the total number of collisions with the walls per unit time increases and the

area of the walls decreases. (e) Although the average force with which the molecules collide with the walls remains constant, the pressure increases because there are more collisions per unit area of wall per unit time.

Check In a conceptual exercise of this kind, there is no numerical answer to check. All we can check in such cases is our reasoning in the course of solving the problem. The increase in pressure seen in part (e) is consistent with Boyle's law.

Practice Exercise 1

Consider two gas cylinders of the same volume and temperature, one containing 1.0 mol of propane, C_3H_8 , and the other 2.0 mol of methane, CH_4 . Which of the following statements is true? (a) The C_3H_8 and CH_4 molecules have the same u_{rms} , (b) The C_3H_8 and CH_4 molecules have the same average kinetic energy, (c) The rate at which the molecules collide with the cylinder walls is the same for both cylinders, (d) The gas pressure is the same in both cylinders.

Practice Exercise 2

How is the rms speed of N_2 molecules in a gas sample changed by (a) an increase in temperature, (b) an increase in volume, (c) mixing with a sample of Ar at the same temperature?

A Closer Look

The Ideal-Gas Equation

The ideal-gas equation can be derived from the five statements given in the text for the kinetic-molecular theory. Rather than perform the derivation, however, let's consider in qualitative terms how the ideal-gas equation might follow from these statements. The total force of the molecular collisions on the walls and hence the pressure (force per unit area, Section 10.2) produced by these collisions depend both on how strongly the molecules strike the walls (impulse imparted per collision) and on the rate at which the collisions occur:

 $P \propto \text{impulse imparted per collision} \times \text{collision rate}$

For a molecule traveling at the rms speed, the impulse imparted by a collision with a wall depends on the momentum of the molecule; that is, it depends on the product of the molecule's mass and speed: $mu_{\rm rms}$. The collision rate is proportional to the number of molecules per unit volume, n/V, and to their speed, which is $u_{\rm rms}$ because we are talking about only molecules traveling at this speed. Thus, we have

$$P \propto mu_{\rm rms} \times \frac{n}{V} \times u_{\rm rms} \propto \frac{nm(u_{\rm rms})^2}{V}$$
 [10.17]

Because the average kinetic energy, $\frac{1}{2}m(u_{\rm rms})^2$, is proportional to temperature, we have $m(u_{\rm rms})^2 \propto T$. Making this substitution in Equation 10.17 gives

$$P \propto \frac{nm(u_{\rm rms})^2}{V} \propto \frac{nT}{V}$$
 [10.18]

If we put in a proportionality constant, calling it R, the gas constant, you can see that we obtain the ideal-gas equation:

$$P = \frac{nRT}{V}$$
 [10.19]

Swiss mathematician Daniel Bernoulli (1700–1782) conceived of a model for gases that was, for all practical purposes, the same as the model described by the kinetic-molecular theory of gases. From this model, Bernoulli derived Boyle's law and the ideal-gas equation. His was one of the first examples in science of developing a mathematical model from a set of assumptions, or hypothetical statements. However, Bernoulli's work on this subject was completely ignored, only to be rediscovered a hundred years later by Clausius and others. It was ignored because it conflicted with popular beliefs and was in conflict with Isaac Newton's incorrect model for gases. Those idols of the times had to fall before the way was clear for the kinetic-molecular theory. As this story illustrates, science is not a straight road running from here to the "truth." The road is built by humans, so it zigs and zags.

10.8 | Molecular Effusion and Diffusion

According to the kinetic-molecular theory of gases, the average kinetic energy of *any* collection of gas molecules, $\frac{1}{2}m(u_{\rm rms})^2$, has a specific value at a given temperature. Thus, for two gases at the same temperature a gas composed of low-mass particles, such as He, has the same average kinetic energy as one composed of more massive particles, such as Xe. The mass of the particles in the He sample is smaller than that in the

GO FIGURE

Which of these gases has the largest molar mass? Which has the smallest?

▲ Figure 10.14 The effect of molar mass on molecular speed at 25 °C.

Xe sample. Consequently, the He particles must have a higher rms speed than the Xe particles. The equation that expresses this fact quantitatively is

$$u_{\rm rms} = \sqrt{\frac{3RT}{\mathcal{M}}}$$
 [10.20]

where \mathcal{M} is the molar mass of the particles, which can be derived from the kineticmolecular theory. Because M appears in the denominator, the less massive the gas particles, the higher their rms speed.

▲ Figure 10.14 shows the distribution of molecular speeds for several gases at 25 °C. Notice how the distributions are shifted toward higher speeds for gases of lower molar masses. The most probable speed of a gas molecule can also be derived:

$$u_{\rm mp} = \sqrt{\frac{2RT}{\mathcal{M}}}$$
 [10.21]

Give It Some Thought

What is the ratio of $u_{\rm rms}$ to $u_{\rm mp}$ for a sample of ${\rm O_2}(g)$ at 300 K? Will this ratio change as the temperature changes? Will it be different for a different gas?

SAMPLE EXERCISE 10.13 Calculating a Root-Mean-Square Speed

Calculate the rms speed of the molecules in a sample of N₂ gas at 25 °C.

SOLUTION

Analyze We are given the identity of a gas and the temperature, the two quantities we need to calculate the rms speed.

Plan We calculate the rms speed using Equation 10.20.

Solve We must convert each quantity in our equation to SI units. We will also use R in units of J/mol-K (Table 10.2) to make the units cancel correctly.

$$T = 25 + 273 = 298 \text{ K}$$

$$\mathcal{M} = 28.0 \text{ g/mol} = 28.0 \times 10^{-3} \text{ kg/mol}$$

$$R = 8.314 \text{ J/mol-K} = 8.314 \text{ kg-m}^2/\text{s}^2\text{-mol-K} \quad \text{(Since 1 J} = 1 \text{ kg-m}^2/\text{s}^2\text{)}$$

$$u_{\text{rms}} = \sqrt{\frac{3(8.314 \text{ kg-m}^2/\text{s}^2\text{-mol-K})(298 \text{ K})}{28.0 \times 10^{-3} \text{ kg/mol}}} = 5.15 \times 10^2 \text{ m/s}$$

Comment This corresponds to a speed of 1150 mi/hr. Because the average molecular weight of air molecules is slightly greater than that of N_2 , the rms speed of air molecules is a little smaller than that for N_2 .

Practice Exercise 1

Fill in the blanks for the following statement: The rms speed of the molecules in a sample of H_2 gas at 300 K will be _____ times larger than the rms speed of O_2 molecules at the same temperature, and the ratio $u_{rms}(H_2)/u_{rms}(O_2)$ _____ with increasing temperature. (a) four, will not change, (b) four, will increase, (c) sixteen, will not change, (d) sixteen, will decrease (e) Not enough information is given to answer this question.

Practice Exercise 2

What is the rms speed of an atom in a sample of He gas at 25 °C?

The dependence of molecular speed on mass has two interesting consequences. The first is **effusion**, which is the escape of gas molecules through a tiny hole (▶ **Figure 10.15**). The second is **diffusion**, which is the spread of one substance throughout a space or throughout a second substance. For example, the molecules of a perfume diffuse throughout a room.

Graham's Law of Effusion

In 1846, Thomas Graham (1805–1869) discovered that the effusion rate of a gas is inversely proportional to the square root of its molar mass. Assume we have two gases at the same temperature and pressure in two containers with identical pinholes. If the rates of effusion of the two gases are r_1 and r_2 and their molar masses are \mathcal{M}_1 and \mathcal{M}_2 , **Graham's law** states that

$$\frac{r_1}{r_2} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}} \tag{10.22}$$

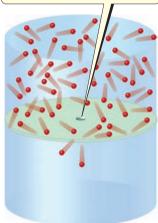

a relationship that indicates that the lighter gas has the higher effusion rate.

The only way for a molecule to escape from its container is for it to "hit" the hole in the partitioning wall of Figure 10.15. The faster the molecules are moving the more often they hit the partition wall and the greater the likelihood that a molecule will hit the hole and effuse. This implies that the rate of effusion is directly proportional to the rms speed of the molecules. Because *R* and *T* are constant, we have, from Equation 10.22

$$\frac{r_1}{r_2} = \frac{u_{\text{rms1}}}{u_{\text{rms2}}} = \sqrt{\frac{3RT/\mathcal{M}_1}{3RT/\mathcal{M}_2}} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}}$$
 [10.23]

As expected from Graham's law, helium escapes from containers through tiny pinhole leaks more rapidly than other gases of higher molecular weight (Figure 10.16).

Gas molecules in top half effuse through pinhole only when they happen to hit the pinhole

▲ Figure 10.15 Effusion.

SAMPLE EXERCISE 10.14 Applying Graham's Law

An unknown gas composed of homonuclear diatomic molecules effuses at a rate that is 0.355 times the rate at which O_2 gas effuses at the same temperature. Calculate the molar mass of the unknown and identify it.

SOLUTION

Analyze We are given the rate of effusion of an unknown gas relative to that of O_2 and asked to find the molar mass and identity of the unknown. Thus, we need to connect relative rates of effusion to relative molar masses.

Plan We use Equation 10.22 to determine the molar mass of the unknown gas. If we let r_x and \mathcal{M}_x represent the rate of effusion and molar mass of the gas, we can write

$$\frac{r_x}{r_{\rm O_2}} = \sqrt{\frac{\mathcal{M}_{\rm O_2}}{\mathcal{M}_x}}$$

Solve From the information given,

 $r_x = 0.355 \times r_{O_2}$

Thus,

$$\frac{r_x}{r_{O_2}} = 0.355 = \sqrt{\frac{32.0 \text{ g/mol}}{M_x}}$$

$$\frac{32.0 \text{ g/mol}}{\mathcal{M}_r} = (0.355)^2 = 0.126$$

$$M_x = \frac{32.0 \,\mathrm{g/mol}}{0.126} = 254 \,\mathrm{g/mol}$$

Because we are told that the unknown gas is composed of homonuclear diatomic molecules, it must be an element. The molar mass must represent twice the atomic weight of the atoms in the unknown gas. We conclude that the unknown gas must have an atomic weight of 127 g/mol and therefore is I_2 .

Practice Exercise 1

In a system for separating gases, a tank containing a mixture of hydrogen and carbon dioxide is connected to a much larger tank where the pressure is kept very low. The two tanks are separated by a porous membrane through which the molecules must effuse. If the initial partial pressure of each gas is 5.00 atm, what will be the mole fraction of hydrogen in the tank after the partial pressure of carbon dioxide has declined to 4.50 atm? (a) 52.1%, (b) 37.2%, (c) 32.1%, (d) 4.68%, (e) 27.4%.

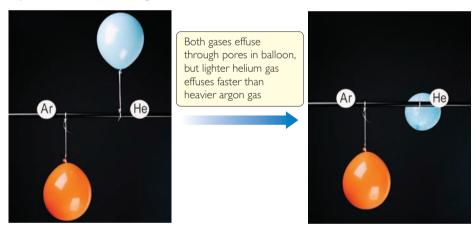

Practice Exercise 2

Calculate the ratio of the effusion rates of N₂ gas and O₂ gas.

GO FIGURE

Because pressure and temperature are constant in this figure but volume changes, which other quantity in the ideal-gas equation must also change?

▲ Figure 10.16 An illustration of Graham's law of effusion.

Diffusion and Mean Free Path

Although diffusion, like effusion, is faster for lower-mass molecules than for higher-mass ones, molecular collisions make diffusion more complicated than effusion.

Graham's law, Equation 10.22, approximates the ratio of the diffusion rates of two gases under identical conditions. We can see from the horizontal axis in Figure 10.14 that the speeds of molecules are quite high. For example, the rms speed of molecules of N_2 gas at room temperature is 515 m/s. In spite of this high speed, if someone opens a vial of perfume at one end of a room, some time elapses—perhaps a few minutes—before the scent is detected at the other end of the room. This tells us that the diffusion rate of gases throughout a volume of space is much

Chemistry Put to Work

Gas Separations

The fact that lighter molecules move at higher average speeds than more massive ones has many interesting applications. For example, developing the atomic bomb during World War II required scientists to separate the relatively low-abundance uranium isotope 235 U (0.7%) from the much more abundant 238 U (99.3%). This separation was accomplished by converting the uranium into a volatile compound, UF₆, that was then allowed to pass through a porous barrier (∇ Figure 10.17). Because of the pore diameters, this process is not simple effusion. Nevertheless, the way in which rate of passing through the pores depends on molar mass is essentially the same as that in effusion. The slight difference in molar mass between 235 UF₆ and 238 UF₆ caused the molecules to move at slightly different rates:

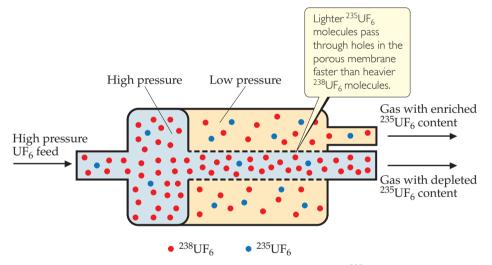

$$\frac{r_{235}}{r_{238}} = \sqrt{\frac{352.04}{349.03}} = 1.0043$$

Thus, the gas initially appearing on the opposite side of the barrier is very slightly enriched in ²³⁵U. The process is repeated thousands

of times, leading to a nearly complete separation of the two isotopes. Because of the large number of steps needed to adequately separate the isotopes, gaseous diffusion facilities are large-scale structures. The largest diffusion plant in the United States is located outside of Paducah, Kentucky. It contains approximately 400 miles of piping and the buildings where the separation takes place take up over 75 acres.

An increasingly popular method of separating uranium isotopes is by a technique that uses centrifuges. In this procedure, cylindrical rotors containing UF $_6$ vapor spin at high speed inside an evacuated casing. Molecules of $^{238}{\rm UF}_6$ move closer to the spinning walls, whereas molecules of $^{235}{\rm UF}_6$ remain in the middle of the cylinders. A stream of gas moves the $^{235}{\rm UF}_6$ from the center of one centrifuge into another. Plants that use centrifuges consume less energy than those that use effusion and can be constructed in a more compact, modular fashion. Such plants are frequently in the news today as countries such as Iran and North Korea enrich uranium in the $^{235}{\rm U}$ isotope for both nuclear power and nuclear weaponry.

Related Exercises: 10.87, 10.88

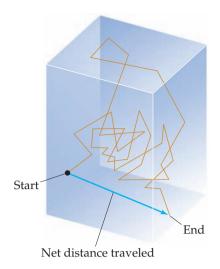

▲ Figure 10.17 Uranium enrichment by gaseous diffusion. The lighter 235 UF $_6$ effuses through a porous barrier at a slightly faster rate than 238 UF $_6$. The pressure difference across the membrane drives the effusion. The enrichment shown here for a single step is exaggerated for illustrative purposes.

slower than molecular speeds.* This difference is due to molecular collisions, which occur frequently for a gas at atmospheric pressure—about 10¹⁰ times per second for each molecule. Collisions occur because real gas molecules have finite volumes.

Because of molecular collisions, the direction of motion of a gas molecule is constantly changing. Therefore, the diffusion of a molecule from one point to another

^{*}The rate at which the perfume moves across the room also depends on how well stirred the air is from temperature gradients and the movement of people. Nevertheless, even with the aid of these factors, it still takes much longer for the molecules to traverse the room than one would expect from their rms speed.

▲ Figure 10.18 Diffusion of a gas molecule. For clarity, no other gas molecules in the container are shown.

consists of many short, straight-line segments as collisions buffet it around in random directions (◀ Figure 10.18).

The average distance traveled by a molecule between collisions, called the molecule's **mean free path**, varies with pressure as the following analogy illustrates. Imagine walking through a shopping mall. When the mall is crowded (high pressure), the average distance you can walk before bumping into someone is short (short mean free path). When the mall is empty (low pressure), you can walk a long way (long mean free path) before bumping into someone. The mean free path for air molecules at sea level is about 60 nm. At about 100 km in altitude, where the air density is much lower, the mean free path is about 10 cm, over 1 million times longer than at the Earth's surface.

Give It Some Thought

Will these changes increase, decrease, or have no effect on the mean free path of the molecules in a gas sample?

- (a) increasing pressure.
- (b) increasing temperature.

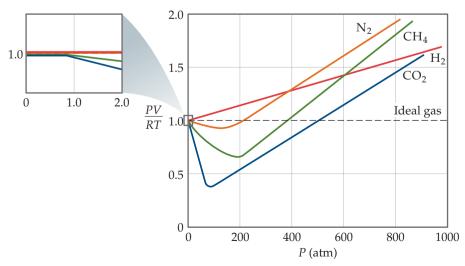

10.9 | Real Gases: Deviations from Ideal Behavior

The extent to which a real gas departs from ideal behavior can be seen by rearranging the ideal-gas equation to solve for *n*:

$$\frac{PV}{RT} = n ag{10.24}$$

This form of the equation tells us that for 1 mol of ideal gas, the quantity PV/RT equals 1 at all pressures. In ∇ Figure 10.19, PV/RT is plotted as a function of P for 1 mol of several real gases. At high pressures (generally above 10 atm), the deviation from ideal behavior (PV/RT=1) is large and different for each gas. Real gases, in other words, do not behave ideally at high pressure. At lower pressures (usually below 10 atm), however, the deviation from ideal behavior is small, and we can use the ideal-gas equation without generating serious error.

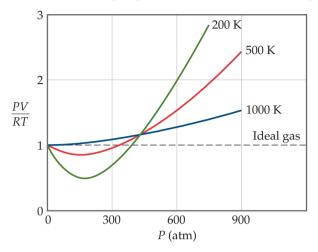

Deviation from ideal behavior also depends on temperature. As temperature increases, the behavior of a real gas more nearly approaches that of the ideal gas

▲ Figure 10.19 The effect of pressure on the behavior of several real gases. Data for 1 mol of gas in all cases. Data for N_2 , CH_4 , and H_2 are at 300 K; for CO_2 data are at 313 K because under high pressure CO_2 liquefies at 300 K.

▲ GO FIGURE

True or false: Nitrogen gas behaves more like an ideal gas as the temperature increases.

▲ Figure 10.20 The effect of temperature and pressure on the behavior of nitrogen gas.

(**Figure 10.20**). In general, *the deviation from ideal behavior increases as temperature decreases*, becoming significant near the temperature at which the gas liquefies.

Give It Some Thought

Under which conditions do you expect helium gas to deviate most from ideal behavior? (a) 100 K and 1 atm, (b) 100 K and 5 atm, (c) 300 K and 2 atm.

The basic assumptions of the kinetic-molecular theory of gases give us insight into why real gases deviate from ideal behavior. The molecules of an ideal gas are assumed to occupy no space and have no attraction for one another. Real molecules, however, do have finite volumes and do attract one another. As Figure 10.21 shows, the unoccupied space in which real molecules can move is less than the container volume. At low pressures, the combined volume of the gas molecules is negligible relative to the container volume. Thus, the unoccupied volume available to the molecules is essentially the container volume. At high pressures, the combined volume of the gas molecules is not negligible relative to the container volume. Now the unoccupied volume available to the molecules is less than the container volume. At high pressures, therefore, gas volumes tend to be slightly greater than those predicted by the ideal-gas equation.

Another reason for nonideal behavior at high pressures is that the attractive forces between molecules come into play at the short intermolecular distances found when molecules are crowded together at high pressures. Because of these attractive forces, the impact of a given molecule with the container wall is lessened. If we could stop the motion in a gas, as illustrated in Figure 10.22, we would see that a molecule about to collide with the wall experiences the attractive forces of nearby molecules. These attractions lessen the force with which the mole-

Gas molecules occupy a small fraction of the total volume.

Gas molecules occupy a larger fraction of the total volume.

Low pressure

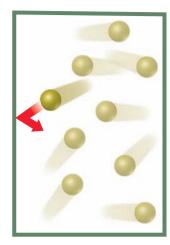

High pressure

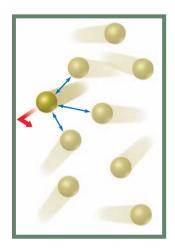

▲ Figure 10.21 Gases behave more ideally at low pressure than at high pressure.

cule hits the wall. As a result, the gas pressure is less than that of an ideal gas. This effect decreases PV/RT to below its ideal value, as seen at the lower pressures in Figures 10.19 and 10.20. When the pressure is sufficiently high, however, the volume effects dominate and PV/RT increases to above the ideal value.

GO FIGURE

How would you expect the pressure of a gas to change if suddenly the intermolecular forces were repulsive rather than attractive?

Ideal gas

Real gas

▲ Figure 10.22 In any real gas, attractive intermolecular forces reduce pressure to values lower than in an ideal gas.

Temperature determines how effective attractive forces between gas molecules are in causing deviations from ideal behavior at lower pressures. Figure 10.20 shows that, at pressures below about 400 atm, cooling increases the extent to which a gas deviates from ideal behavior. As the gas cools, the average kinetic energy of the molecules decreases. This drop in kinetic energy means the molecules do not have the energy needed to overcome intermolecular attraction, and the molecules will be more likely to stick to each other than bounce off each other.

As the temperature of a gas increases—as, say, from 200 to 1000 K in Figure 10.20—the negative deviation of PV/RT from the ideal value of 1 disappears. As noted earlier, the deviations seen at high temperatures stem mainly from the effect of the finite volumes of the molecules.

Give It Some Thought

Explain the negative deviation from ideal gas behavior of N_2 below 300 atm in Figure 10.20.

The van der Waals Equation

Engineers and scientists who work with gases at high pressures often cannot use the ideal-gas equation because departures from ideal behavior are too large. One useful equation developed to predict the behavior of real gases was proposed by the Dutch scientist Johannes van der Waals (1837–1923).

As we have seen, a real gas has a lower pressure due to intermolecular forces, and a larger volume due to the finite volume of the molecules, relative to an ideal gas. Van der Waals recognized that it would be possible to retain the form of the ideal-gas equation, PV = nRT, if corrections were made to the pressure and the volume. He introduced two constants for these corrections: a, a measure of how strongly the gas molecules attract one another, and b, a measure of the finite volume occupied by the molecules. His description of gas behavior is known as the **van der Waals equation**:

$$\left(P + \frac{n^2 a}{V^2}\right)(V - nb) = nRT$$
 [10.25]

The term n^2a/V^2 accounts for the attractive forces. The equation adjusts the pressure upward by adding n^2a/V^2 because attractive forces between molecules tend to reduce the pressure (Figure 10.22). The added term has the form n^2a/V^2 because the attractive force between pairs of molecules increases as the square of the number of molecules per unit volume, $(n/V)^2$.

The term nb accounts for the small but finite volume occupied by the gas molecules (Figure 10.21). The van der Waals equation subtracts nb to adjust the volume downward to give the volume that would be available to the molecules in the ideal case. The constants a and b, called van van

SAMPLE EXERCISE 10.15 Using the van der Waals Equation

If 10.00 mol of an ideal gas were confined to 22.41 L at 0.0 $^{\circ}$ C, it would exert a pressure of 10.00 atm. Use the van der Waals equation and Table 10.3 to estimate the pressure exerted by 1.000 mol of Cl₂(g) in 22.41 L at 0.0 $^{\circ}$ C.

SOLUTION

Analyze We need to determine a pressure. Because we will use the van der Waals equation, we must identify the appropriate values for the constants in the equation.

Plan Rearrange Equation 10.25 to isolate P.

Solve Substituting n=10.00 mol, R=0.08206 L-atm/mol-K, T=273.2 K, V=22.41 L, a=6.49 L²-atm/mol², and b=0.0562 L/mol:

$$P = \frac{(10.00 \text{ mol})(0.08206 \text{ L-atm/mol-K})(273.2 \text{ K})}{22.41 \text{ L} - (10.00 \text{ mol})(0.0562 \text{ L/mol})} - \frac{(10.00 \text{ mol})^2(6.49 \text{ L}^2\text{-atm/mol}^2)}{(22.41 \text{ L})^2}$$
$$= 10.26 \text{ atm} - 1.29 \text{ atm} = 8.97 \text{ atm}$$

Comment Notice that the term 10.26 atm is the pressure corrected for molecular volume. This value is higher than the ideal value, 10.00 atm, because the volume in which the molecules are free to move is smaller than the container volume, 22.41 L. Thus, the molecules collide more frequently with the container walls and the pressure is higher than that of a real gas. The term 1.29 atm makes a correction in the opposite direction for intermolecular forces. The correction for intermolecular forces is the larger of the two and thus the pressure 8.97 atm is smaller than would be observed for an ideal gas.

Practice Exercise 1

Calculate the pressure of a 2.975-mol sample of N₂ in a 0.7500-L flask at 300.0 °C using the van der Waals equation and then repeat the calculation using the ideal-gas equation. Within the limits of the significant figures justified by these parameters, will the ideal-gas equation overestimate or underestimate the pressure, and if so by how much?

- (a) Underestimate by 17.92 atm, (b) Overestimate by 21.87 atm,
- (c) Underestimate by 0.06 atm, (d) Overestimate by 0.06 atm.

Practice Exercise 2

A sample of 1.000 mol of $CO_2(g)$ is confined to a 3.000-L container at 0.000 °C. Calculate the pressure of the gas using (a) the ideal-gas equation and (b) the van der Waals equation.

SAMPLE

INTEGRATIVE EXERCISE Putting Concepts Together

Cyanogen, a highly toxic gas, is 46.2% C and 53.8% N by mass. At 25 °C and 751 torr, 1.05 g of cyanogen occupies 0.500 L. (a) What is the molecular formula of cyanogen? Predict (b) its molecular structure and (c) its polarity.

SOLUTION

Analyze We need to determine the molecular formula of a gas from elemental analysis data and data on its properties. Then we need to predict the structure of the molecule and from that, its polarity.

(a) Plan We can use the percentage composition of the compound to calculate its empirical formula. ∞ (Section 3.5) Then we can determine the molecular formula by comparing the mass of the empirical formula with the molar mass. (Section 3.5)

Solve To determine the empirical formula, we assume we have a 100-g sample and calculate the number of moles of each element in the sample:

Moles C =
$$(46.2 \text{ g C}) \left(\frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 3.85 \text{ mol C}$$

Moles N =
$$(53.8 \text{ g N}) \left(\frac{1 \text{ mol N}}{14.01 \text{ g N}} \right) = 3.84 \text{ mol N}$$

Because the ratio of the moles of the two elements is essentially 1:1, the empirical formula is CN. To determine the molar mass, we use Equation 10.11.

$$\mathcal{M} = \frac{dRT}{P} = \frac{(1.05 \text{ g}/0.500 \text{ L})(0.08206 \text{ L-atm/mol-K})(298 \text{ K})}{(751/760) \text{atm}} = 52.0 \text{ g/mol}$$

The molar mass associated with the empirical formula CN is 12.0 + 14.0 = 26.0 g/mol. Dividing the molar mass by that of its empirical formula gives (52.0 g/mol)/(26.0 g/mol) = 2.00. Thus, the molecule has twice as many atoms of each element as the empirical formula, giving the molecular formula C_2N_2 .

(b) Plan To determine the molecular structure, we must determine the Lewis structure. (Section 8.5) We can then use the VSEPR model to predict the structure. (Section 9.2)

Solve The molecule has 2(4) + 2(5) = 18 valence-shell electrons. By trial and error, we seek a Lewis structure with 18 valence electrons in which each atom has an octet and the formal charges are as low as possible. The structure

$$:N = C - C = N:$$

meets these criteria. (This structure has zero formal charge on each atom.)

The Lewis structure shows that each atom has two electron domains. (Each nitrogen has a nonbonding pair of electrons and a triple bond, whereas each carbon has a triple bond and a single bond.) Thus, the electron-domain geometry around each atom is linear, causing the overall molecule to be linear.

(c) Plan To determine the polarity of the molecule, we must examine the polarity of the individual bonds and the overall geometry of the molecule.

Solve Because the molecule is linear, we expect the two dipoles created by the polarity in the carbon-nitrogen bond to cancel each other, leaving the molecule with no dipole moment.

Chapter Summary and Key Terms

CHARACTERISTICS OF GASES (SECTION 10.1) Substances that are gases at room temperature tend to be molecular substances with low molar masses. Air, a mixture composed mainly of N_2 and O_2 , is the most common gas we encounter. Some liquids and solids can also exist in the gaseous state, where they are known as **vapors**. Gases are compressible; they mix in all proportions because their component molecules are far apart from each other.

PRESSURE (SECTION 10.2) To describe the state or condition of a gas, we must specify four variables: pressure (P), volume (V), temperature (T), and quantity (n). Volume is usually measured in liters, temperature in kelvins, and quantity of gas in moles. **Pressure** is the force per unit area and is expressed in SI units as **pascals**, Pa $(1 \text{ Pa} = 1 \text{ N/m}^2)$. A related unit, the **bar**, equals 10^5 Pa. In chemistry, **standard atmospheric pressure** is used to define the **atmosphere** (atm) and the **torr** (also called the millimeter of mercury). One atmosphere of pressure equals 101.325 kPa, or 760 torr. A barometer is often used to measure the atmospheric pressure. A manometer can be used to measure the pressure of enclosed gases.

THE GAS LAWS (SECTION 10.3) Studies have revealed several simple gas laws: For a constant quantity of gas at constant temperature, the volume of the gas is inversely proportional to the pressure (Boyle's law). For a fixed quantity of gas at constant pressure, the volume is directly proportional to its absolute temperature (Charles's law). Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules (Avogadro's hypothesis). For a gas at constant temperature and pressure, the volume of the gas is directly proportional to the number of moles of gas (Avogadro's law). Each of these gas laws is a special case of the ideal-gas equation.

THE IDEAL-GAS EQUATION (SECTIONS 10.4 AND 10.5) The ideal-gas equation, PV = nRT, is the equation of state for an ideal gas. The term R in this equation is the gas constant. We can use the ideal-gas equation to calculate variations in one variable when one or more of the others are changed. Most gases at pressures less than 10 atm and temperatures near 273 K and above obey the ideal-gas equation reasonably well. The conditions of 273 K (0 °C) and 1 atm are known as the standard temperature and pressure (STP). In all applications of the ideal-gas equation we must remember to convert temperatures to the absolute-temperature scale (the kelvin scale).

Using the ideal-gas equation, we can relate the density of a gas to its molar mass: $\mathcal{M} = dRT/P$. We can also use the ideal-gas equation to solve problems involving gases as reactants or products in chemical reactions.

GAS MIXTURES AND PARTIAL PRESSURES (SECTION 10.6) In gas mixtures, the total pressure is the sum of the **partial pressures** that each gas would exert if it were present alone under the same conditions (**Dalton's law of partial pressures**). The partial pressure of a component of a mixture is equal to its mole fraction times the total pressure: $P_1 = X_1P_t$. The **mole fraction** X is the ratio of the moles of one

THE KINETIC-MOLECULAR THEORY OF GASES (SECTION 10.7)

component of a mixture to the total moles of all components.

The kinetic-molecular theory of gases accounts for the properties of an ideal gas in terms of a set of statements about the nature of gases. Briefly, these statements are as follows: Molecules are in continuous chaotic motion. The volume of gas molecules is negligible compared to the volume of their container. The gas molecules neither attract nor repel each other. The average kinetic energy of the gas molecules is proportional to the absolute temperature and does not change if the temperature remains constant.

The individual molecules of a gas do not all have the same kinetic energy at a given instant. Their speeds are distributed over a wide range; the distribution varies with the molar mass of the gas and with temperature. The **root-mean-square (rms) speed**, $u_{\rm rms}$, varies in proportion to the square root of the absolute temperature and inversely with the square root of the molar mass: $u_{\rm rms} = \sqrt{3RT/M}$. The most probable speed of a gas molecule is given by $u_{\rm mp} = \sqrt{2RT/M}$.

MOLECULAR EFFUSION AND DIFFUSION (SECTION 10.8) It follows from kinetic-molecular theory that the rate at which a gas undergoes effusion (escapes through a tiny hole) is inversely proportional to the square root of its molar mass (Graham's law). The diffusion of one gas through the space occupied by a second gas is another phenomenon related to the speeds at which molecules move. Because moving molecules undergo frequent collisions with one another, the mean free path—the mean distance traveled between collisions—is short. Collisions between molecules limit the rate at which a gas molecule can diffuse.

REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR (SECTION

10.9) Departures from ideal behavior increase in magnitude as pressure increases and as temperature decreases. Real gases depart from ideal behavior because (1) the molecules possess finite volume and (2) the molecules experience attractive forces for one another. These two effects make the volumes of real gases larger and their pressures smaller than those of an ideal gas. The van der Waals equation is an equation of state for gases, which modifies the ideal-gas equation to account for intrinsic molecular volume and intermolecular forces.

Learning Outcomes After studying this chapter, you should be able to:

- Convert between pressure units with an emphasis on torr and atmospheres. (Section 10.2)
- Calculate P, V, n, or T using the ideal-gas equation. (Section 10.4)
- Explain how the gas laws relate to the ideal-gas equation and apply the gas laws in calculations. (Sections 10.3 and 10.4)
- Calculate the density or molecular weight of a gas. (Section 10.5)
- Calculate the volume of gas consumed or formed in a chemical reaction. (Section 10.5)
- Calculate the total pressure of a gas mixture given its partial pressures or given information for calculating partial pressures. (Section 10.6)
- Describe the kinetic-molecular theory of gases and how it explains the pressure and temperature of a gas, the gas laws, and the rates of effusion and diffusion. (Sections 10.7 and 10.8)
- Explain why intermolecular attractions and molecular volumes cause real gases to deviate from ideal behavior at high pressure or low temperature. (Section 10.9)

Exercises

Visualizing Concepts

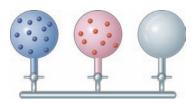

- **10.1** Mars has an average atmospheric pressure of 0.007 atm. Would it be easier or harder to drink from a straw on Mars than on Earth? Explain. [Section 10.2]
- 10.2 You have a sample of gas in a container with a movable piston, such as the one in the drawing. (a) Redraw the container to show what it might look like if the temperature of the gas is increased from 300 to 500 K while the pressure is kept constant.
 (b) Redraw the container to show what it might look like if the external pressure on the piston is increased from 1.0 atm to 2.0 atm while the temperature is kept constant. (c) Redraw the container to show what it might look like if the temperature of the gas decreases from 300 to 200 K while the pressure is kept constant (assume the gas does not liquefy). [Section 10.3]

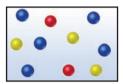

10.3 Consider the sample of gas depicted here. What would the drawing look like if the volume and temperature remained constant while you removed enough of the gas to decrease the pressure by a factor of 2? [Section 10.3]

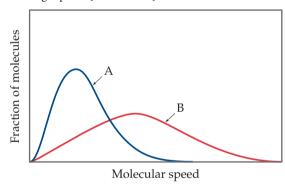

- 10.4 Imagine that the reaction $2 \operatorname{CO}(g) + \operatorname{O}_2(g) \longrightarrow 2 \operatorname{CO}_2(g)$ occurs in a container that has a piston that moves to maintain a constant pressure when the reaction occurs at constant temperature. Which of the following statements describes how the volume of the container changes due to the reaction: (a) the volume increases by 50%, (b) the volume increases by 33%, (c) the volume remains constant, (d) the volume decreases by 33%, (e) the volume decreases by 50%. [Sections 10.3 and 10.4]
- 10.5 Suppose you have a fixed amount of an ideal gas at a constant volume. If the pressure of the gas is doubled while the volume is held constant, what happens to its temperature? [Section 10.4]
- 10.6 The apparatus shown here has two gas-filled containers and one empty container, all attached to a hollow horizontal tube. When the valves are opened and the gases are allowed to mix at constant temperature, what is the distribution of atoms in each container? Assume that the containers are of equal volume and ignore the volume of the connecting tube. Which gas has the greater partial pressure after the valves are opened? [Section 10.6]

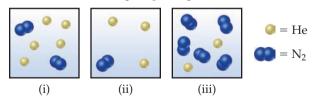

10.7 The accompanying drawing represents a mixture of three different gases. (a) Rank the three components in order of increasing partial pressure. (b) If the total pressure of the mixture is 1.40 atm, calculate the partial pressure of each gas. [Section 10.6]

- 10.8 On a single plot, qualitatively sketch the distribution of molecular speeds for (a) Kr(g) at -50 °C, (b) Kr(g) at 0 °C, (c) Ar(g) at 0 °C. [Section 10.7]
- 10.9 Consider the following graph. (a) If curves A and B refer to two different gases, He and O₂, at the same temperature, which curve corresponds to He? (b) If A and B refer to the same gas at two different temperatures, which represents the higher temperature? (c) For each curve which speed is highest: the most probable speed, the root-mean-square speed, or the average speed? [Section 10.7]

10.10 Consider the following samples of gases:

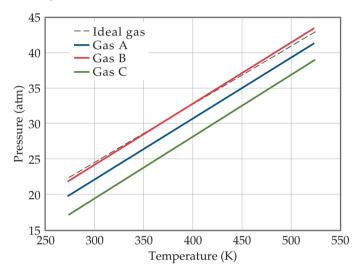

If the three samples are all at the same temperature, rank them with respect to (a) total pressure, (b) partial pressure of helium, (c) density, (d) average kinetic energy of particles. [Section 10.6 and 10.7]

10.11 A thin glass tube 1 m long is filled with Ar gas at 1 atm, and the ends are stoppered with cotton plugs:

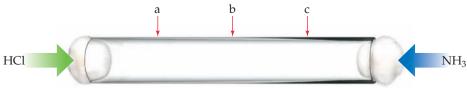

HCl gas is introduced at one end of the tube, and simultaneously NH_3 gas is introduced at the other end. When the two gases diffuse through the cotton plugs down the tube and meet, a white ring appears due to the formation of $NH_4Cl(s)$. At which location—a, b, or c—do you expect the ring to form? [Section 10.8]

10.12 The graph below shows the change in pressure as the temperature increases for a 1-mol sample of a gas confined to a 1-L container. The four plots correspond to an ideal gas and three real gases: CO₂, N₂, and Cl₂. (a) At room temperature, all three real gases have a pressure less than the ideal gas. Which van der Waals constant, a or b, accounts for the influence intermolecular forces have in lowering the pressure of a real gas? (b) Use the van der Waals constants in Table 10.3 to match the labels in the plot (A, B, and C) with the respective gases (CO₂, N₂, and Cl₂). [Section 10.9]

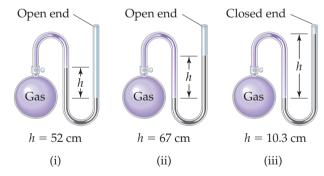

Gas Characteristics; Pressure (Sections 10.1 and 10.2)

- 10.13 How does a gas compare with a liquid for each of the following properties: (a) density, (b) compressibility, (c) ability to mix with other substances of the same phase to form homogeneous mixtures, (d) ability to conform to the shape of its container?
- 10.14 (a) A liquid and a gas are moved to larger containers. How does their behavior differ once they are in the larger containers? Explain the difference in molecular terms. (b) Although liquid water and carbon tetrachloride, $\mathrm{CCl}_4(l)$, do not mix, their vapors form a homogeneous mixture. Explain. (c) Gas densities are generally reported in grams per liter, whereas liquid densities are reported in grams per milliliter. Explain the molecular basis for this difference.
- 10.15 Suppose that a woman weighing 130 lb and wearing high-heeled shoes momentarily places all her weight on the heel of one foot. If the area of the heel is 0.50 in.², calculate the pressure exerted on the underlying surface in (a) kilopascals, (b) atmospheres, and (c) pounds per square inch.

- 10.16 A set of bookshelves rests on a hard floor surface on four legs, each having a cross-sectional dimension of 3.0×4.1 cm in contact with the floor. The total mass of the shelves plus the books stacked on them is 262 kg. Calculate the pressure in pascals exerted by the shelf footings on the surface.
- 10.17 (a) How high in meters must a column of water be to exert a pressure equal to that of a 760-mm column of mercury? The density of water is 1.0 g/mL, whereas that of mercury is 13.6 g/mL. (b) What is the pressure, in atmospheres, on the body of a diver if he or she is 39 ft below the surface of the water when atmospheric pressure at the surface is 0.97 atm?
- 10.18 The compound 1-iodododecane is a nonvolatile liquid with a density of 1.20 g/mL. The density of mercury is 13.6 g/mL. What do you predict for the height of a barometer column based on 1-iodododecane, when the atmospheric pressure is 749 torr?
- 10.19 The typical atmospheric pressure on top of Mt. Everest (29,028 ft) is about 265 torr. Convert this pressure to (a) atm, (b) mm Hg, (c) pascals, (d) bars, (e) psi.
- 10.20 Perform the following conversions: (a) 0.912 atm to torr,
 (b) 0.685 bar to kilopascals, (c) 655 mm Hg to atmospheres,
 (d) 1.323 × 10⁵ Pa to atmospheres, (e) 2.50 atm to psi.
- 10.21 In the United States, barometric pressures are generally reported in inches of mercury (in. Hg). On a beautiful summer day in Chicago, the barometric pressure is 30.45 in. Hg. (a) Convert this pressure to torr. (b) Convert this pressure to atm.
- 10.22 Hurricane Wilma of 2005 is the most intense hurricane on record in the Atlantic basin, with a low-pressure reading of 882 mbar (millibars). Convert this reading into (a) atmospheres, (b) torr, and (c) inches of Hg.
- **10.23** If the atmospheric pressure is 0.995 atm, what is the pressure of the enclosed gas in each of the three cases depicted in the drawing? Assume that the gray liquid is mercury.

10.24 An open-end manometer containing mercury is connected to a container of gas, as depicted in Sample Exercise 10.2. What is the pressure of the enclosed gas in torr in each of the following situations? (a) The mercury in the arm attached to the gas is 15.4 mm higher than in the one open to the atmosphere; atmospheric pressure is 0.985 atm. (b) The mercury in the arm attached to the gas is 12.3 mm lower than in the one open to the atmosphere; atmospheric pressure is 0.99 atm.

The Gas Laws (Section 10.3)

10.25 You have a gas at 25 °C confined to a cylinder with a movable piston. Which of the following actions would double

- the gas pressure? (a) Lifting up on the piston to double the volume while keeping the temperature constant; (b) Heating the gas so that its temperature rises from 25 °C to 50 °C, while keeping the volume constant; (c) Pushing down on the piston to halve the volume while keeping the temperature constant.
- 10.26 A fixed quantity of gas at 21 °C exhibits a pressure of 752 torr and occupies a volume of 5.12 L. (a) Calculate the volume the gas will occupy if the pressure is increased to 1.88 atm while the temperature is held constant. (b) Calculate the volume the gas will occupy if the temperature is increased to 175 °C while the pressure is held constant.
- 10.27 (a) Amonton's law expresses the relationship between pressure and temperature. Use Charles's law and Boyle's law to derive the proportionality relationship between *P* and *T*.
 (b) If a car tire is filled to a pressure of 32.0 lbs/in.² (psi) measured at 75 °F, what will be the tire pressure if the tires heat up to 120 °F during driving?
- 10.28 Nitrogen and hydrogen gases react to form ammonia gas as follows:

$$N_2(g) + 3 H_2(g) \longrightarrow 2 NH_3(g)$$

At a certain temperature and pressure, 1.2 L of N_2 reacts with 3.6 L of H_2 . If all the N_2 and H_2 are consumed, what volume of NH_3 , at the same temperature and pressure, will be produced?

The Ideal-Gas Equation (Section 10.4)

- 10.29 (a) What conditions are represented by the abbreviation STP? (b) What is the molar volume of an ideal gas at STP? (c) Room temperature is often assumed to be 25 °C. Calculate the molar volume of an ideal gas at 25 °C and 1 atm pressure. (d) If you measure pressure in bars instead of atmospheres, calculate the corresponding value of *R* in L-bar/mol-K.
- 10.30 To derive the ideal-gas equation, we assume that the volume of the gas atoms/molecules can be neglected. Given the atomic radius of neon, 0.69 Å, and knowing that a sphere has a volume of $4\pi r^3/3$, calculate the fraction of space that Ne atoms occupy in a sample of neon at STP.
- 10.31 Suppose you are given two 1-L flasks and told that one contains a gas of molar mass 30, the other a gas of molar mass 60, both at the same temperature. The pressure in flask A is X atm, and the mass of gas in the flask is 1.2 g. The pressure in flask B is 0.5X atm, and the mass of gas in that flask is 1.2 g. Which flask contains the gas of molar mass 30, and which contains the gas of molar mass 60?
- 10.32 Suppose you are given two flasks at the same temperature, one of volume 2 L and the other of volume 3 L. The 2-L flask contains 4.8 g of gas, and the gas pressure is X atm. The 3-L flask contains 0.36 g of gas, and the gas pressure is 0.1X. Do the two gases have the same molar mass? If not, which contains the gas of higher molar mass?
- 10.33 Complete the following table for an ideal gas:

P	V	n	T
2.00 atm	1.00 L	0.500 mol	? K
0.300 atm	0.250 L	? mol	27 °C
650 torr	? L	0.333 mol	350 K
? atm	585 mL	0.250 mol	295 K

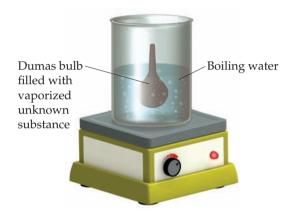

- 10.34 Calculate each of the following quantities for an ideal gas: (a) the volume of the gas, in liters, if 1.50 mol has a pressure of 1.25 atm at a temperature of -6 °C; (b) the absolute temperature of the gas at which 3.33×10^{-3} mol occupies 478 mL at 750 torr; (c) the pressure, in atmospheres, if 0.00245 mol occupies 413 mL at 138 °C; (d) the quantity of gas, in moles, if 126.5 L at 54 °C has a pressure of 11.25 kPa.
- 10.35 The Goodyear blimps, which frequently fly over sporting events, hold approximately 175,000 ft³ of helium. If the gas is at 23 °C and 1.0 atm, what mass of helium is in a blimp?
- 10.36 A neon sign is made of glass tubing whose inside diameter is 2.5 cm and whose length is 5.5 m. If the sign contains neon at a pressure of 1.78 torr at 35 °C, how many grams of neon are in the sign? (The volume of a cylinder is $\pi r^2 h$.)
- 10.37 (a) Calculate the number of molecules in a deep breath of air whose volume is 2.25 L at body temperature, 37 °C, and a pressure of 735 torr. (b) The adult blue whale has a lung capacity of 5.0×10^3 L. Calculate the mass of air (assume an average molar mass of 28.98 g/mol) contained in an adult blue whale's lungs at 0.0 °C and 1.00 atm, assuming the air behaves ideally.
- 10.38 (a) If the pressure exerted by ozone, O_3 , in the stratosphere is 3.0×10^{-3} atm and the temperature is 250 K, how many ozone molecules are in a liter? (b) Carbon dioxide makes up approximately 0.04% of Earth's atmosphere. If you collect a 2.0-L sample from the atmosphere at sea level (1.00 atm) on a warm day (27 °C), how many CO_2 molecules are in your sample?
- 10.39 A scuba diver's tank contains 0.29 kg of O_2 compressed into a volume of 2.3 L. (a) Calculate the gas pressure inside the tank at 9 °C. (b) What volume would this oxygen occupy at 26 °C and 0.95 atm?
- 10.40 An aerosol spray can with a volume of 250 mL contains 2.30 g of propane gas (C_3H_8) as a propellant. (a) If the can is at 23 °C, what is the pressure in the can? (b) What volume would the propane occupy at STP? (c) The can's label says that exposure to temperatures above 130 °F may cause the can to burst. What is the pressure in the can at this temperature?
- **10.41** A 35.1 g sample of solid CO_2 (dry ice) is added to a container at a temperature of 100 K with a volume of 4.0 L. If the container is evacuated (all of the gas removed), sealed and then allowed to warm to room temperature (T = 298 K) so that all of the solid CO_2 is converted to a gas, what is the pressure inside the container?
- 10.42 A 334-mL cylinder for use in chemistry lectures contains 5.225 g of helium at 23 °C. How many grams of helium must be released to reduce the pressure to 75 atm assuming ideal gas behavior?
- 10.43 Chlorine is widely used to purify municipal water supplies and to treat swimming pool waters. Suppose that the volume of a particular sample of Cl_2 gas is 8.70 L at 895 torr and 24 °C. (a) How many grams of Cl_2 are in the sample? (b) What volume will the Cl_2 occupy at STP? (c) At what temperature will the volume be 15.00 L if the pressure is 8.76 \times 10² torr? (d) At what pressure will the volume equal 5.00 L if the temperature is 58 °C?
- 10.44 Many gases are shipped in high-pressure containers. Consider a steel tank whose volume is 55.0 gallons that contains O₂ gas at a pressure of 16,500 kPa at 23 °C. (a) What mass of O₂ does the tank contain? (b) What volume would the gas occupy at STP? (c) At what temperature would the pressure in the tank equal 150.0 atm? (d) What would be the pressure of the gas, in kPa, if it were transferred to a container at 24 °C whose volume is 55.0 L?

- 10.45 In an experiment reported in the scientific literature, male cockroaches were made to run at different speeds on a miniature treadmill while their oxygen consumption was measured. In 1 hr the average cockroach running at 0.08 km/hr consumed 0.8 mL of O₂ at 1 atm pressure and 24 °C per gram of insect mass. (a) How many moles of O₂ would be consumed in 1 hr by a 5.2-g cockroach moving at this speed? (b) This same cockroach is caught by a child and placed in a 1-qt fruit jar with a tight lid. Assuming the same level of continuous activity as in the research, will the cockroach consume more than 20% of the available O₂ in a 48-hr period? (Air is 21 mol % O₂.)
- 10.46 The physical fitness of athletes is measured by " $V_{\rm O_2}$ max," which is the maximum volume of oxygen consumed by an individual during incremental exercise (for example, on a treadmill). An average male has a $V_{\rm O_2}$ max of 45 mL $\rm O_2/kg$ body mass/min, but a world-class male athlete can have a $V_{\rm O_2}$ max reading of 88.0 mL $\rm O_2/kg$ body mass/min. (a) Calculate the volume of oxygen, in mL, consumed in 1 hr by an average man who weighs 185 lbs and has a $V_{\rm O_2}$ max reading of 47.5 mL $\rm O_2/kg$ body mass/min. (b) If this man lost 20 lb, exercised, and increased his $V_{\rm O_2}$ max to 65.0 mL $\rm O_2/kg$ body mass/min, how many mL of oxygen would he consume in 1 hr?

Further Applications of the Ideal-Gas Equation (Section 10.5)

- 10.47 Which gas is most dense at 1.00 atm and 298 K: CO_2 , N_2O , or Cl_2 ? Explain.
- **10.48** Rank the following gases from least dense to most dense at 1.00 atm and 298 K: SO₂, HBr, CO₂. Explain.
- **10.49** Which of the following statements best explains why a closed balloon filled with helium gas rises in air?
 - (a) Helium is a monatomic gas, whereas nearly all the molecules that make up air, such as nitrogen and oxygen, are diatomic.
 - (b) The average speed of helium atoms is greater than the average speed of air molecules, and the greater speed of collisions with the balloon walls propels the balloon upward.
 - (c) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The mass of the balloon is thus less than the mass of the air displaced by its volume.
 - (d) Because helium has a lower molar mass than the average air molecule, the helium atoms are in faster motion. This means that the temperature of the helium is greater than the air temperature. Hot gases tend to rise.
- **10.50** Which of the following statements best explains why nitrogen gas at STP is less dense than Xe gas at STP?
 - (a) Because Xe is a noble gas, there is less tendency for the Xe atoms to repel one another, so they pack more densely in the gaseous state.
 - (b) Xe atoms have a higher mass than N₂ molecules. Because both gases at STP have the same number of molecules per unit volume, the Xe gas must be denser.
 - (c) The Xe atoms are larger than N_2 molecules and thus take up a larger fraction of the space occupied by the gas.
 - (d) Because the Xe atoms are much more massive than the N₂ molecules, they move more slowly and thus exert less upward force on the gas container and make the gas appear denser.

- 10.51 (a) Calculate the density of NO_2 gas at 0.970 atm and 35 °C. (b) Calculate the molar mass of a gas if 2.50 g occupies 0.875 L at 685 torr and 35 °C.
- **10.52** (a) Calculate the density of sulfur hexafluoride gas at 707 torr and 21 °C. (b) Calculate the molar mass of a vapor that has a density of 7.135 g/L at 12 °C and 743 torr.
- 10.53 In the Dumas-bulb technique for determining the molar mass of an unknown liquid, you vaporize the sample of a liquid that boils below 100 °C in a boiling-water bath and determine the mass of vapor required to fill the bulb. From the following data, calculate the molar mass of the unknown liquid: mass of unknown vapor, 1.012 g; volume of bulb, 354 cm³; pressure, 742 torr; temperature, 99 °C.

- 10.54 The molar mass of a volatile substance was determined by the Dumas-bulb method described in Exercise 10.53. The unknown vapor had a mass of 0.846 g; the volume of the bulb was 354 cm³, pressure 752 torr, and temperature 100 °C. Calculate the molar mass of the unknown vapor.
- 10.55 Magnesium can be used as a "getter" in evacuated enclosures to react with the last traces of oxygen. (The magnesium is usually heated by passing an electric current through a wire or ribbon of the metal.) If an enclosure of 0.452 L has a partial pressure of O_2 of 3.5×10^{-6} torr at 27 °C, what mass of magnesium will react according to the following equation?

$$2 \operatorname{Mg}(s) + \operatorname{O}_2(g) \longrightarrow 2 \operatorname{MgO}(s)$$

10.56 Calcium hydride, CaH₂, reacts with water to form hydrogen gas:

$$CaH_2(s) + 2 H_2O(l) \longrightarrow Ca(OH)_2(aq) + 2 H_2(g)$$

This reaction is sometimes used to inflate life rafts, weather balloons, and the like, when a simple, compact means of generating $\rm H_2$ is desired. How many grams of $\rm CaH_2$ are needed to generate 145 L of $\rm H_2$ gas if the pressure of $\rm H_2$ is 825 torr at 21 °C?

10.57 The metabolic oxidation of glucose, $C_6H_{12}O_6$, in our bodies produces CO_2 , which is expelled from our lungs as a gas:

$$C_6H_{12}O_6(aq) + 6 O_2(g) \longrightarrow 6 CO_2(g) + 6 H_2O(l)$$

(a) Calculate the volume of dry CO_2 produced at body temperature (37 °C) and 0.970 atm when 24.5 g of glucose is consumed in this reaction. (b) Calculate the volume of oxygen you would need, at 1.00 atm and 298 K, to completely oxidize 50.0 g of glucose.

10.58 Both Jacques Charles and Joseph Louis Guy-Lussac were avid balloonists. In his original flight in 1783, Jacques Charles used a balloon that contained approximately 31,150 L of H₂. He generated the H₂ using the reaction between iron and hydrochloric acid:

$$Fe(s) + 2 HCl(aq) \longrightarrow FeCl_2(aq) + H_2(g)$$

How many kilograms of iron were needed to produce this volume of H_2 if the temperature was 22 °C?

10.59 Hydrogen gas is produced when zinc reacts with sulfuric acid:

$$Zn(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + H_2(g)$$

If 159 mL of wet $\rm H_2$ is collected over water at 24 °C and a barometric pressure of 738 torr, how many grams of Zn have been consumed? (The vapor pressure of water is tabulated in Appendix B.)

10.60 Acetylene gas, $C_2H_2(g)$, can be prepared by the reaction of calcium carbide with water:

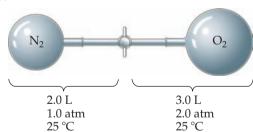

$$CaC_2(s) + 2 H_2O(l) \longrightarrow Ca(OH)_2(aq) + C_2H_2(q)$$

Calculate the volume of C_2H_2 that is collected over water at 23 °C by reaction of 1.524 g of CaC_2 if the total pressure of the gas is 753 torr. (The vapor pressure of water is tabulated in Appendix B.)

Partial Pressures (Section 10.6)

10.61 Consider the apparatus shown in the following drawing.

(a) When the valve between the two containers is opened and the gases allowed to mix, how does the volume occupied by the N₂ gas change? What is the partial pressure of N₂ after mixing? (b) How does the volume of the O₂ gas change when the gases mix? What is the partial pressure of O₂ in the mixture? (c) What is the total pressure in the container after the gases mix?

- 10.62 Consider a mixture of two gases, A and B, confined in a closed vessel. A quantity of a third gas, C, is added to the same vessel at the same temperature. How does the addition of gas C affect the following: (a) the partial pressure of gas A, (b) the total pressure in the vessel, (c) the mole fraction of gas B?
- 10.63 A mixture containing 0.765 mol He(g), 0.330 mol Ne(g), and 0.110 mol Ar(g) is confined in a 10.00-L vessel at 25 °C.
 (a) Calculate the partial pressure of each of the gases in the mixture.
 (b) Calculate the total pressure of the mixture.
- 10.64 A deep-sea diver uses a gas cylinder with a volume of 10.0 L and a content of 51.2 g of $\rm O_2$ and 32.6 g of He. Calculate the partial pressure of each gas and the total pressure if the temperature of the gas is 19 °C.
- 10.65 The atmospheric concentration of CO_2 gas is presently 390 ppm (parts per million, by volume; that is, 390 L of every 10^6 L of the atmosphere are CO_2). What is the mole fraction of CO_2 in the atmosphere?

- 10.66 A plasma-screen TV contains thousands of tiny cells filled with a mixture of Xe, Ne, and He gases that emits light of specific wavelengths when a voltage is applied. A particular plasma cell, 0.900 mm × 0.300 mm × 10.0 mm, contains 4% Xe in a 1:1 Ne:He mixture at a total pressure of 500 torr. Calculate the number of Xe, Ne, and He atoms in the cell and state the assumptions you need to make in your calculation.
- 10.67 A piece of dry ice (solid carbon dioxide) with a mass of 5.50 g is placed in a 10.0-L vessel that already contains air at 705 torr and 24 $^{\circ}$ C. After the carbon dioxide has totally sublimed, what is the partial pressure of the resultant CO₂ gas, and the total pressure in the container at 24 $^{\circ}$ C?
- 10.68 A sample of 5.00 mL of diethylether ($C_2H_5OC_2H_5$, density = 0.7134 g/mL) is introduced into a 6.00-L vessel that already contains a mixture of N_2 and O_2 , whose partial pressures are $P_{N_2} = 0.751$ atm and $P_{O_2} = 0.208$ atm. The temperature is held at 35.0 °C, and the diethylether totally evaporates. (a) Calculate the partial pressure of the diethylether. (b) Calculate the total pressure in the container.
- **10.69** A rigid vessel containing a 3:1 mol ratio of carbon dioxide and water vapor is held at 200 °C where it has a total pressure of 2.00 atm. If the vessel is cooled to 10 °C so that all of the water vapor condenses, what is the pressure of carbon dioxide? Neglect the volume of the liquid water that forms on cooling.
- 10.70 If 5.15~g of Ag_2O is sealed in a 75.0-mL tube filled with 760 torr of $N_2~g$ as at $32~^{\circ}C$, and the tube is heated to $320~^{\circ}C$, the Ag_2O decomposes to form oxygen and silver. What is the total pressure inside the tube assuming the volume of the tube remains constant?
- **10.71** At an underwater depth of 250 ft, the pressure is 8.38 atm. What should the mole percent of oxygen be in the diving gas for the partial pressure of oxygen in the mixture to be 0.21 atm, the same as in air at 1 atm?
- 10.72 (a) What are the mole fractions of each component in a mixture of 15.08 g of O_2 , 8.17 g of N_2 , and 2.64 g of H_2 ? (b) What is the partial pressure in atm of each component of this mixture if it is held in a 15.50-L vessel at 15 °C?
- 10.73 A quantity of N_2 gas originally held at 5.25 atm pressure in a 1.00-L container at 26 °C is transferred to a 12.5-L container at 20 °C. A quantity of O_2 gas originally at 5.25 atm and 26 °C in a 5.00-L container is transferred to this same container. What is the total pressure in the new container?
- 10.74 A sample of 3.00 g of $SO_2(g)$ originally in a 5.00-L vessel at 21 °C is transferred to a 10.0-L vessel at 26 °C. A sample of 2.35 g of $N_2(g)$ originally in a 2.50-L vessel at 20 °C is transferred to this same 10.0-L vessel. (a) What is the partial pressure of $SO_2(g)$ in the larger container? (b) What is the partial pressure of $N_2(g)$ in this vessel? (c) What is the total pressure in the vessel?

Kinetic-Molecular Theory of Gases; Effusion and Diffusion (Sections 10.7 and 10.8)

10.75 Determine whether each of the following changes will increase, decrease, or not affect the rate with which gas molecules collide with the walls of their container: (a) increasing the volume of the container, (b) increasing the temperature, (c) increasing the molar mass of the gas.

- 10.76 Indicate which of the following statements regarding the kinetic-molecular theory of gases are correct. (a) The average kinetic energy of a collection of gas molecules at a given temperature is proportional to m^{1/2}. (b) The gas molecules are assumed to exert no forces on each other. (c) All the molecules of a gas at a given temperature have the same kinetic energy. (d) The volume of the gas molecules is negligible in comparison to the total volume in which the gas is contained. (e) All gas molecules move with the same speed if they are at the same temperature.
- 10.77 Which assumptions are common to both kinetic-molecular theory and the ideal-gas equation?
- 10.78 Newton had an incorrect theory of gases in which he assumed that all gas molecules repel one another and the walls of their container. Thus, the molecules of a gas are statically and uniformly distributed, trying to get as far apart as possible from one another and the vessel walls. This repulsion gives rise to pressure. Explain why Charles's law argues for the kinetic-molecular theory and against Newton's model.
- **10.79** WF₆ is one of the heaviest known gases. How much slower is the root-mean-square speed of WF₆ than He at 300 K?
- [10.80] You have an evacuated container of fixed volume and known mass and introduce a known mass of a gas sample. Measuring the pressure at constant temperature over time, you are surprised to see it slowly dropping. You measure the mass of the gas-filled container and find that the mass is what it should be—gas plus container—and the mass does not change over time, so you do not have a leak. Suggest an explanation for your observations.
 - 10.81 The temperature of a 5.00-L container of N₂ gas is increased from 20 °C to 250 °C. If the volume is held constant, predict qualitatively how this change affects the following: (a) the average kinetic energy of the molecules; (b) the root-mean-square speed of the molecules; (c) the strength of the impact of an average molecule with the container walls; (d) the total number of collisions of molecules with walls per second.
- 10.82 Suppose you have two 1-L flasks, one containing N₂ at STP, the other containing CH₄ at STP. How do these systems compare with respect to (a) number of molecules, (b) density, (c) average kinetic energy of the molecules, (d) rate of effusion through a pinhole leak?
- **10.83** (a) Place the following gases in order of increasing average molecular speed at 25 °C: Ne, HBr, SO₂, NF₃, CO. (b) Calculate the rms speed of NF₃ molecules at 25 °C. (c) Calculate the most probable speed of an ozone molecule in the stratosphere, where the temperature is 270 K.
- **10.84** (a) Place the following gases in order of increasing average molecular speed at 300 K: CO, SF₆, H₂S, Cl₂, HBr. (b) Calculate the rms speeds of CO and Cl₂ molecules at 300 K. (c) Calculate the most probable speeds of CO and Cl₂ molecules at 300 K.
- **10.85** Explain the difference between effusion and diffusion.
- [10.86] At constant pressure, the mean free path (λ) of a gas molecule is directly proportional to temperature. At constant temperature, λ is inversely proportional to pressure. If you compare two different gas molecules at the same temperature and pressure, λ is inversely proportional to the square of the diameter of the gas molecules. Put these facts together to create a formula for the mean free path of a gas molecule with a proportionality constant (call it $R_{\rm mfp}$, like the ideal-gas constant) and define units for $R_{\rm mfp}$.

- 10.87 Hydrogen has two naturally occurring isotopes, ¹H and ²H. Chlorine also has two naturally occurring isotopes, ³⁵Cl and ³⁷Cl. Thus, hydrogen chloride gas consists of four distinct types of molecules: ¹H³⁵Cl, ¹H³⁷Cl, ²H³⁵Cl, and ²H³⁷Cl. Place these four molecules in order of increasing rate of effusion.
- 10.88 As discussed in the "Chemistry Put to Work" box in Section 10.8, enriched uranium can be produced by effusion of gaseous UF₆ across a porous membrane. Suppose a process were developed to allow effusion of gaseous uranium atoms, U(g). Calculate the ratio of effusion rates for ²³⁵U and ²³⁸U, and compare it to the ratio for UF₆ given in the essay.
- 10.89 Arsenic(III) sulfide sublimes readily, even below its melting point of 320 °C. The molecules of the vapor phase are found to effuse through a tiny hole at 0.28 times the rate of effusion of Ar atoms under the same conditions of temperature and pressure. What is the molecular formula of arsenic(III) sulfide in the gas phase?
- 10.90 A gas of unknown molecular mass was allowed to effuse through a small opening under constant-pressure conditions. It required 105 s for 1.0 L of the gas to effuse. Under identical experimental conditions it required 31 s for 1.0 L of $\rm O_2$ gas to effuse. Calculate the molar mass of the unknown gas. (Remember that the faster the rate of effusion, the shorter the time required for effusion of 1.0 L; in other words, rate is the amount that diffuses over the time it takes to diffuse.)

Nonideal-Gas Behavior (Section 10.9)

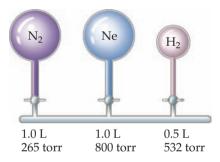

- 10.91 (a) List two experimental conditions under which gases deviate from ideal behavior. (b) List two reasons why the gases deviate from ideal behavior.
- 10.92 The planet Jupiter has a surface temperature of 140 K and a mass 318 times that of Earth. Mercury (the planet) has a surface temperature between 600 K and 700 K and a mass 0.05 times that of Earth. On which planet is the atmosphere more likely to obey the ideal-gas law? Explain.

- **10.93** Based on their respective van der Waals constants (Table 10.3), is Ar or CO₂ expected to behave more nearly like an ideal gas at high pressures? Explain.
- **10.94** Briefly explain the significance of the constants a and b in the van der Waals equation.
- 10.95 In Sample Exercise 10.16, we found that one mole of Cl₂ confined to 22.41 L at 0 °C deviated slightly from ideal behavior. Calculate the pressure exerted by 1.00 mol Cl₂ confined to a smaller volume, 5.00 L, at 25 °C. (a) First use the ideal-gas equation and (b) then use the van der Waals equation for your calculation. (Values for the van der Waals constants are given in Table 10.3.) (c) Why is the difference between the result for an ideal gas and that calculated using the van der Waals equation greater when the gas is confined to 5.00 L compared to 22.4 L?
- 10.96 Calculate the pressure that CCl_4 will exert at 40 °C if 1.00 mol occupies 33.3 L, assuming that (a) CCl_4 obeys the idealgas equation; (b) CCl_4 obeys the van der Waals equation. (Values for the van der Waals constants are given in Table 10.3.) (c) Which would you expect to deviate more from ideal behavior under these conditions, Cl_2 or CCl_4 ? Explain.
- [10.97] Table 10.3 shows that the van der Waals b parameter has units of L/mol. This implies that we can calculate the size of atoms or molecules from b. Using the value of b for Xe, calculate the radius of a Xe atom and compare it to the value found in Figure 7.7, that is, 1.40 Å. Recall that the volume of a sphere is $(4/3)\pi r^3$.
- [10.98] Table 10.3 shows that the van der Waals *b* parameter has units of L/mol. This means that we can calculate the sizes of atoms or molecules from the *b* parameter. Refer back to the discussion in Section 7.3. Is the van der Waals radius we calculate from the *b* parameter of Table 10.3 more closely associated with the bonding or nonbonding atomic radius discussed there? Explain.

Additional Exercises

- **10.99** A gas bubble with a volume of 1.0 mm³ originates at the bottom of a lake where the pressure is 3.0 atm. Calculate its volume when the bubble reaches the surface of the lake where the pressure is 730 torr, assuming that the temperature doesn't change.
- 10.100 A 15.0-L tank is filled with helium gas at a pressure of 1.00×10^2 atm. How many balloons (each 2.00 L) can be inflated to a pressure of 1.00 atm, assuming that the temperature remains constant and that the tank cannot be emptied below 1.00 atm?
- 10.101 To minimize the rate of evaporation of the tungsten filament, 1.4×10^{-5} mol of argon is placed in a 600-cm³ lightbulb. What is the pressure of argon in the lightbulb at 23 °C?
- 10.102 Carbon dioxide, which is recognized as the major contributor to global warming as a "greenhouse gas," is formed when fossil fuels are combusted, as in electrical power plants
- fueled by coal, oil, or natural gas. One potential way to reduce the amount of CO_2 added to the atmosphere is to store it as a compressed gas in underground formations. Consider a 1000-megawatt coal-fired power plant that produces about 6×10^6 tons of CO_2 per year. (a) Assuming ideal-gas behavior, 1.00 atm, and 27 °C, calculate the volume of CO_2 produced by this power plant. (b) If the CO_2 is stored underground as a liquid at 10 °C and 120 atm and a density of $1.2 \,\mathrm{g/cm^3}$, what volume does it possess? (c) If it is stored underground as a gas at 36 °C and 90 atm, what volume does it occupy?
- 10.103 Propane, C_3H_8 , liquefies under modest pressure, allowing a large amount to be stored in a container. (a) Calculate the number of moles of propane gas in a 110-L container at 3.00 atm and 27 °C. (b) Calculate the number of moles of liquid propane that can be stored in the same volume if the density of the liquid is 0.590 g/mL. (c) Calculate the ratio of the number of moles of liquid to moles of gas. Discuss this ratio in light of the kinetic-molecular theory of gases.

- [10.104] Nickel carbonyl, Ni(CO)₄, is one of the most toxic substances known. The present maximum allowable concentration in laboratory air during an 8-hr workday is 1 ppb (parts per billion) by volume, which means that there is one mole of Ni(CO)₄ for every 10^9 moles of gas. Assume 24 °C and 1.00 atm pressure. What mass of Ni(CO)₄ is allowable in a laboratory room that is 12 ft \times 20 ft \times 9 ft?
- 10.105 When a large evacuated flask is filled with argon gas, its mass increases by 3.224 g. When the same flask is again evacuated and then filled with a gas of unknown molar mass, the mass increase is 8.102 g. (a) Based on the molar mass of argon, estimate the molar mass of the unknown gas. (b) What assumptions did you make in arriving at your answer?
- 10.106 Consider the arrangement of bulbs shown in the drawing. Each of the bulbs contains a gas at the pressure shown. What is the pressure of the system when all the stopcocks are opened, assuming that the temperature remains constant? (We can neglect the volume of the capillary tubing connecting the bulbs.)

- 10.107 Assume that a single cylinder of an automobile engine has a volume of $524\,\mathrm{cm^3}$. (a) If the cylinder is full of air at $74\,^\circ\mathrm{C}$ and 0.980 atm, how many moles of O_2 are present? (The mole fraction of O_2 in dry air is 0.2095.) (b) How many grams of C_8H_{18} could be combusted by this quantity of O_2 , assuming complete combustion with formation of CO_2 and H_2O ?
- 10.108 Assume that an exhaled breath of air consists of 74.8% N_2 , 15.3% O_2 , 3.7% CO_2 , and 6.2% water vapor. (a) If the total pressure of the gases is 0.985 atm, calculate the partial pressure of each component of the mixture. (b) If the volume of the exhaled gas is 455 mL and its temperature is 37 °C, calculate the number of moles of CO_2 exhaled. (c) How many grams of glucose $(C_6H_{12}O_6)$ would need to be metabolized to produce this quantity of CO_2 ? (The chemical reaction is the same as that for combustion of $C_6H_{12}O_6$. See Section 3.2 and Problem 10.57.)
- 10.109 A 1.42-g sample of helium and an unknown mass of O_2 are mixed in a flask at room temperature. The partial pressure of the helium is 42.5 torr, and that of the oxygen is 158 torr. What is the mass of the oxygen?
- [10.110] An ideal gas at a pressure of 1.50 atm is contained in a bulb of unknown volume. A stopcock is used to connect this bulb with a previously evacuated bulb that has a volume of 0.800 L as shown here. When the stopcock is opened the gas expands into the empty bulb. If the temperature is held constant during this process and the final pressure is 695 torr, what is the volume of the bulb that was originally filled with gas?

10.111 The density of a gas of unknown molar mass was measured as a function of pressure at 0 °C, as in the table that follows.(a) Determine a precise molar mass for the gas. [*Hint:* Graph d/P versus P.] (b) Why is d/P not a constant as a function of pressure?

Pressure (atm)	1.00	0.666	0.500	0.333	0.250
Density (g/L)	2.3074	1.5263	1.1401	0.7571	0.5660

- 10.112 A glass vessel fitted with a stopcock valve has a mass of 337.428 g when evacuated. When filled with Ar, it has a mass of 339.854 g. When evacuated and refilled with a mixture of Ne and Ar, under the same conditions of temperature and pressure, it has a mass of 339.076 g. What is the mole percent of Ne in the gas mixture?
- 10.113 You have a sample of gas at -33 °C. You wish to increase the rms speed by a factor of 2. To what temperature should the gas be heated?
- 10.114 Consider the following gases, all at STP: Ne, SF₆, N₂, CH₄. (a) Which gas is most likely to depart from the assumption of the kinetic-molecular theory that says there are no attractive or repulsive forces between molecules? (b) Which one is closest to an ideal gas in its behavior? (c) Which one has the highest root-mean-square molecular speed at a given temperature? (d) Which one has the highest total molecular volume relative to the space occupied by the gas? (e) Which has the highest average kinetic-molecular energy? (f) Which one would effuse more rapidly than N₂? (g) Which one would have the largest van der Waals b parameter?
- 10.115 Does the effect of intermolecular attraction on the properties of a gas become more significant or less significant if (a) the gas is compressed to a smaller volume at constant temperature; (b) the temperature of the gas is increased at constant volume?
- 10.116 Which of the noble gases other than radon would you expect to depart most readily from ideal behavior? Use the density data in Table 7.8 to show evidence in support of your answer.
- **10.117** It turns out that the van der Waals constant *b* equals four times the total volume actually occupied by the molecules of a mole of gas. Using this figure, calculate the fraction of the volume in a container actually occupied by Ar atoms (**a**) at STP, (**b**) at 200 atm pressure and 0 °C. (Assume for simplicity that the ideal-gas equation still holds.)
- [10.118] Large amounts of nitrogen gas are used in the manufacture of ammonia, principally for use in fertilizers. Suppose 120.00 kg of N₂(g) is stored in a 1100.0-L metal cylinder at 280 °C. (a) Calculate the pressure of the gas, assuming idealgas behavior. (b) By using the data in Table 10.3, calculate the pressure of the gas according to the van der Waals equation. (c) Under the conditions of this problem, which correction dominates, the one for finite volume of gas molecules or the one for attractive interactions?

Integrative Exercises

10.119 Cyclopropane, a gas used with oxygen as a general anesthetic, is composed of 85.7% C and 14.3% H by mass. (a) If 1.56 g of cyclopropane has a volume of 1.00 L at 0.984 atm and 50.0 °C, what is the molecular formula of cyclopropane? (b) Judging from its molecular formula, would you expect cyclopropane to deviate more or less than Ar from ideal-gas behavior at moderately high pressures and room temperature? Explain. (c) Would cyclopropane effuse through a pinhole faster or more slowly than methane, CH₄?

[10.120] Consider the combustion reaction between 25.0 mL of liquid methanol (density = $0.850 \, g/mL$) and 12.5 L of oxygen gas measured at STP. The products of the reaction are $CO_2(g)$ and $H_2O(g)$. Calculate the volume of liquid H_2O formed if the reaction goes to completion and you condense the water vapor.

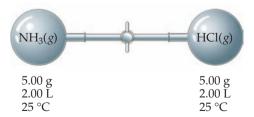

10.121 An herbicide is found to contain only C, H, N, and Cl. The complete combustion of a 100.0-mg sample of the herbicide in excess oxygen produces 83.16 mL of CO₂ and 73.30 mL of H₂O vapor at STP. A separate analysis shows that the sample also contains 16.44 mg of Cl. (a) Determine the percentage of the composition of the substance. (b) Calculate its empirical formula. (c) What other information would you need to know about this compound to calculate its true molecular formula?

10.122 A 4.00-g sample of a mixture of CaO and BaO is placed in a 1.00-L vessel containing CO₂ gas at a pressure of 730 torr and a temperature of 25 °C. The CO₂ reacts with the CaO and BaO, forming CaCO₃ and BaCO₃. When the reaction is complete, the pressure of the remaining CO₂ is 150 torr. (a) Calculate the number of moles of CO₂ that have reacted. (b) Calculate the mass percentage of CaO in the mixture.

[10.123] Ammonia and hydrogen chloride react to form solid ammonium chloride:

$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$$

Two 2.00-L flasks at 25 °C are connected by a valve, as shown in the drawing on the next page. One flask contains 5.00 g of $NH_3(g)$, and the other contains 5.00 g of HCl(g). When the valve is opened, the gases react until one is completely consumed. (a) Which gas will remain in the system after the reaction is complete? (b) What will be the final pressure of the system after the reaction is complete? (Neglect the volume of the ammonium chloride formed.) (c) What mass of ammonium chloride will be formed?

10.124 Gas pipelines are used to deliver natural gas (methane, CH_4) to the various regions of the United States. The total volume of natural gas that is delivered is on the order of $2.7 \times 10^{12} \, L$ per day, measured at STP. Calculate the total enthalpy change for combustion of this quantity of methane.

(*Note*: Less than this amount of methane is actually combusted daily. Some of the delivered gas is passed through to other regions.)

10.125 Chlorine dioxide gas (ClO₂) is used as a commercial bleaching agent. It bleaches materials by oxidizing them. In the course of these reactions, the ClO₂ is itself reduced. (a) What is the Lewis structure for ClO₂? (b) Why do you think that ClO₂ is reduced so readily? (c) When a ClO₂ molecule gains an electron, the chlorite ion, ClO₂⁻, forms. Draw the Lewis structure for ClO₂⁻. (d) Predict the O—Cl—O bond angle in the ClO₂⁻ ion. (e) One method of preparing ClO₂ is by the reaction of chlorine and sodium chlorite:

$$Cl_2(g) + 2 NaClO_2(s) \longrightarrow 2 ClO_2(g) + 2 NaCl(s)$$

If you allow 15.0 g of $NaClO_2$ to react with 2.00 L of chlorine gas at a pressure of 1.50 atm at 21 °C, how many grams of ClO_2 can be prepared?

10.126 Natural gas is very abundant in many Middle Eastern oil fields. However, the costs of shipping the gas to markets in other parts of the world are high because it is necessary to liquefy the gas, which is mainly methane and has a boiling point at atmospheric pressure of -164 °C. One possible strategy is to oxidize the methane to methanol, CH₃OH, which has a boiling point of 65 °C and can therefore be shipped more readily. Suppose that 10.7×10^9 ft³ of methane at atmospheric pressure and 25 °C is oxidized to methanol. (a) What volume of methanol is formed if the density of CH₃OH is 0.791 g/mL? (b) Write balanced chemical equations for the oxidations of methane and methanol to $CO_2(g)$ and $H_2O(l)$. Calculate the total enthalpy change for complete combustion of the 10.7×10^9 ft³ of methane just described and for complete combustion of the equivalent amount of methanol, as calculated in part (a). (c) Methane, when liquefied, has a density of 0.466 g/mL; the density of methanol at 25 °C is 0.791 g/mL. Compare the enthalpy change upon combustion of a unit volume of liquid methane and liquid methanol. From the standpoint of energy production, which substance has the higher enthalpy of combustion per unit volume?

[10.127] Gaseous iodine pentafluoride, IF₅, can be prepared by the reaction of solid iodine and gaseous fluorine:

$$I_2(s) + 5 F_2(g) \longrightarrow 2 IF_5(g)$$

A 5.00-L flask containing 10.0 g of I_2 is charged with 10.0 g of F_2 , and the reaction proceeds until one of the reagents is completely consumed. After the reaction is complete, the temperature in the flask is 125 °C. (a) What is the partial pressure of IF_5 in the flask? (b) What is the mole fraction of IF_5 in the flask (c) Draw the Lewis structure of IF_5 . (d) What is the total mass of reactants and products in the flask?

[10.128] A 6.53-g sample of a mixture of magnesium carbonate and calcium carbonate is treated with excess hydrochloric acid. The resulting reaction produces 1.72 L of carbon dioxide gas at 28 °C and 743 torr pressure. (a) Write balanced chemical equations for the reactions that occur between hydrochloric acid and each component of the mixture. (b) Calculate the total number of moles of carbon dioxide that forms from these reactions. (c) Assuming that the reactions are complete, calculate the percentage by mass of magnesium carbonate in the mixture.

Design an Experiment

You are given a cylinder of an unknown, non-radioactive, noble gas and tasked to determine its molar mass and use that value to identify the gas. The tools available to you are several empty mylar balloons that are about the size of a grapefruit when inflated (gases diffuse through mylar much more slowly than conventional latex balloons), an analytical balance, and three graduated glass beakers of different sizes (100 mL, 500 mL, and 2 L). (a) To how many significant figures would you need to determine the molar mass to identify the gas? (b) Propose an experiment or series of experiments that would allow you to determine the molar mass of the unknown gas. Describe the tools, calculations, and assumptions you would need to use. (c) If you had access to a broader range of analytical instruments, describe an alternative way you could identify the gas using any experimental methods that you have learned about in the earlier chapters.

Liquids and Intermolecular Forces

The lotus plant grows in aquatic environments. To thrive in such an environment the surface of a lotus leaf is highly water repellent. Scientists call surfaces with this property "superhydrophobic." The superhydrophobic character of the lotus leaf not only allows it to float on water but also causes any water that falls on the leaf to bead up and roll off. The water drops collect dirt as they roll off, keeping the leaf clean, even in the muddy ponds and lakes where lotus plants tend to grow. Because of its self-cleaning properties, the lotus plant is considered a symbol of purity in many Eastern cultures.

What forces cause the lotus leaf to repel water so efficiently? Although this plant's self-cleaning nature has been known for millennia, the effect was not fully understood until the 1970s when scanning electron microscopy images revealed a rough, one might say, mountainous, leaf surface (Figure 11.1). The rough surface helps minimize contact between water and leaf.

Another important factor contributing to the plant's self-cleaning nature is the contrast between the molecular composition of the leaf and that of the water. The leaf is coated by hydrocarbon molecules, which are not attracted to water molecules. As a result the water molecules preferentially surround themselves with other water molecules, thereby minimizing their contact with the surface.

The lotus effect has inspired scientists to design superhydrophobic surfaces for applications such as self-cleaning windows and water-repellent clothing. To understand the lotus effect and other phenomena involving liquids and solids, we must understand intermolecular forces, the forces that exist between molecules. Only by understanding

▶ BECAUSE THE LEAVES OF THE LOTUS PLANT are highly water repellent, any water on a leaf beads up to minimize contact with the leaf surface.

11.1 A MOLECULAR COMPARISON OF GASES, LIQUIDS, AND SOLIDS We begin with a comparison of solids, liquids, and

gases from a molecular perspective. This comparison reveals the important roles that temperature and intermolecular forces play in determining the physical state of a substance.

11.2 INTERMOLECULAR FORCES We then examine four intermolecular forces: dispersion forces, dipole-dipole forces, hydrogen bonds, and ion-dipole forces.

11.3 SELECT PROPERTIES OF LIQUIDS We learn that the nature and strength of the intermolecular forces between molecules are largely responsible for many properties of liquids, including viscosity and surface tension.

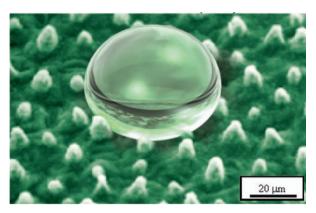

11.4 PHASE CHANGES We explore phase changes—the transitions of matter between the gaseous, liquid, and solid states—and their associated energies.

11.5 VAPOR PRESSURE We examine the dynamic equilibrium that exists between a liquid and its gaseous state and introduce vapor pressure.

11.6 PHASE DIAGRAMS We learn how to read *phase diagrams*, which are graphic representations of the equilibria among the gaseous, liquid, and solid phases.

11.7 LIQUID CRYSTALS We learn about substances that pass into a liquid crystalline phase, which is an intermediate phase between the solid and liquid states. A substance in the liquid crystalline phase has some of the structural order of a solid and some of the freedom of motion of a liquid.

▲ Figure 11.1 A microscopic view of a water droplet on the surface of a lotus leaf.

the nature and strength of these forces can we understand how the composition and structure of a substance are related to its physical properties in the liquid or solid state.

11.1 | A Molecular Comparison of Gases, Liquids, and Solids

As we learned in Chapter 10, the molecules in a gas are widely separated and in a state of constant, chaotic motion. One of the key tenets of kinetic-molecular theory of gases is the assumption that we can neglect the interactions between molecules. ∞ (Section 10.7) The properties of

liquids and solids are quite different from those of gases largely because the intermolecular forces in liquids and solids are much stronger. A comparison of the properties of gases, liquids, and solids is given in ▼ Table 11.1.

In liquids the intermolecular attractive forces are strong enough to hold particles close together. Thus, liquids are much denser and far less compressible than gases. Unlike gases, liquids have a definite volume, independent of the size and shape of their container. The attractive forces in liquids are not strong enough, however, to keep the particles from moving past one another. Thus, any liquid can be poured, and assumes the shape of the container it occupies.

In solids the intermolecular attractive forces are strong enough to hold particles close together and to lock them virtually in place. Solids, like liquids, are not very compressible because the particles have little free space between them. Because the particles in a solid or liquid are fairly close together compared with those of a gas, we often refer to solids and liquids as *condensed phases*. We will study solids in Chapter 12. For now it is sufficient to know that the particles of a solid are not free to undergo long-range movement, which makes solids rigid.*

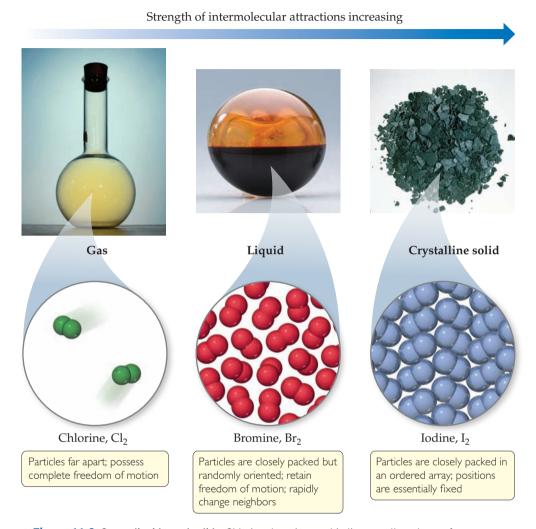

▶ Figure 11.2 compares the three states of matter. The state of a substance depends largely on the balance between the kinetic energies of the particles (atoms, molecules, or

Table 11.1	Some Characteristic Properties of the States of Matter
Gas	Assumes both volume and shape of its container
	Expands to fill its container
	Is compressible
	Flows readily
	Diffusion within a gas occurs rapidly
Liquid	Assumes shape of portion of container it occupies
	Does not expand to fill its container
	Is virtually incompressible
	Flows readily
	Diffusion within a liquid occurs slowly
Solid	Retains own shape and volume
	Does not expand to fill its container
	Is virtually incompressible
	Does not flow
	Diffusion within a solid occurs extremely slowly

^{*}The atoms in a solid are able to vibrate in place. As the temperature of the solid increases, the vibrational motion increases.

GO FIGURE

For a given substance, do you expect the density of the substance in its liquid state to be closer to the density in the gaseous state or in the solid state?

▲ Figure 11.2 Gases, liquids, and solids. Chlorine, bromine, and iodine are all made up of diatomic molecules as a result of covalent bonding. However, due to differences in the strength of the intermolecular forces, they exist in three different states at room temperature and standard pressure: Cl2 gaseous, Br2 liquid, I2 solid.

ions) and the interparticle energies of attraction, as summarized in ▶ Table 11.2. The kinetic energies, which depend on temperature, tend to keep the particles apart and moving. The interparticle attractions tend to draw the particles together. Substances that are gases at room temperature have much weaker interparticle attractions than those that are liquids; substances that are liquids have weaker interparticle attractions than those that are solids. The different states of matter adopted by the halogens at room temperature iodine is a solid, bromine is a liquid, and chlorine is a gas—are a direct consequence of a decrease in the strength of the intermolecular forces as we move from I₂ to Br₂ to Cl₂.

We can change a substance from one state to another by heating or cooling, which changes the average kinetic energy of the particles. NaCl, for example, a solid at room temperature, melts at 1074 K and boils at 1686 K under 1 atm pressure, and Cl₂, a gas at room temperature, liquefies at 239 K and solidifies at 172 K under 1 atm pressure. As the temperature of a gas decreases, the average kinetic energy of its particles decreases, allowing the attractions between the particles to first draw the particles close together, forming a liquid, and then to virtually lock them in place, forming a solid. Increasing the pressure on a gas can also drive transformations from gas to liquid to solid because the increased pressure

Table 11.2 Comparing Kinetic **Energies and Energies of** Attractions for States of Matter

Gas	Kinetic energies >> energies of attraction
Liquid	Comparable kinetic energies and energies of attraction
Solid	Energies of attraction >> kinetic energies

brings the molecules closer together, thus making intermolecular forces more effective. For example, propane (C₃H₈) is a gas at room temperature and 1 atm pressure, whereas liquefied propane (LP) is a liquid at room temperature because it is stored under much higher pressure.

11.2 | Intermolecular Forces

The strengths of intermolecular forces vary over a wide range but are generally much weaker than *intramolecular* forces—ionic, metallic, or covalent bonds (◀ Figure 11.3). Less energy, therefore, is required to vaporize a liquid or melt a solid than to break covalent bonds. For example, only 16 kJ/mol is required to overcome the intermolecular attractions in liquid HCl to vaporize it. In contrast, the energy required to break the covalent bond in HCl is 431 kJ/mol. Thus, when a molecular substance such as HCl changes from solid to liquid to gas, the molecules remain intact.

Many properties of liquids, including boiling points, reflect the strength of the intermolecular forces. A liquid boils when bubbles of its vapor form within the liquid. The molecules of the liquid must overcome their attractive forces to separate and form a vapor. The stronger the attractive forces, the higher the temperature at which the liquid boils. Similarly, the *melting points* of solids increase as the strengths of the intermolecular forces increase. As shown in ▼ Table 11.3, the melting and boiling points of substances in which the particles are held together by chemical bonds tend to be much higher than those of substances in which the particles are held together by intermolecular forces.

Strong intramolecular attraction (covalent bond)

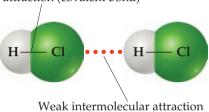

How would you expect the H—CI

line to compare with the H—CI

distance within the HCI molecule?

distance represented by the red dotted

GO FIGURE

▲ Figure 11.3 Intermolecular and intramolecular interactions.

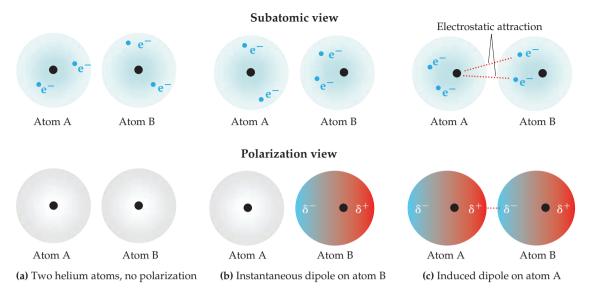

Give It Some Thought

When water boils, what are the bubbles composed of?

Three types of intermolecular attractions exist between electrically neutral molecules: dispersion forces, dipole-dipole attractions, and hydrogen bonding. The first two are collectively called van der Waals forces after Johannes van der Waals, who developed the equation for predicting the deviation of gases from ideal behavior. (Section 10.9) Another kind of attractive force, the ion–dipole force, is important in solutions.

All intermolecular interactions are electrostatic, involving attractions between positive and negative species, much like ionic bonds. (Section 8.2) Why then are intermolecular forces so much weaker than ionic bonds? Recall from Equation 8.4 that electrostatic interactions get stronger as the magnitude of the charges increases and weaker as the distance between charges increases. The charges responsible for intermolecular forces are generally much smaller than the charges in ionic compounds. For example, from its dipole moment it is possible to estimate charges of +0.178and -0.178 for the hydrogen and chlorine ends of the HCl molecule, respectively (see Sample Exercise 8.5). Furthermore, the distances between molecules are often larger than the distances between atoms held together by chemical bonds.

Table 11.3 Melting and Boiling Points of Representative Substances					
Force Holding Particles Together	Substance	Melting Point (K)	Boiling Point (K)		
Chemical bonds

Hydrogen-bonding force	Hydrogen fluoride (HF)	190	293		

▲ Figure 11.4 Dispersion forces. "Snapshots" of the charge distribution for a pair of helium atoms at three instants.

Dispersion Forces

You might think there would be no electrostatic interactions between electrically neutral, nonpolar atoms and/or molecules. Yet some kind of attractive interactions must exist because nonpolar gases like helium, argon, and nitrogen can be liquefied. Fritz London, a German-American physicist, first proposed the origin of this attraction in 1930. London recognized that the motion of electrons in an atom or molecule can create an *instantaneous*, or momentary, dipole moment.

In a collection of helium atoms, for example, the *average* distribution of the electrons about each nucleus is spherically symmetrical as shown in ▲ Figure 11.4(a). The atoms are nonpolar and so possess no permanent dipole moment. The *instantaneous* distribution of the electrons, however, can be different from the average distribution. If we could freeze the motion of the electrons at any given instant, both electrons could be on one side of the

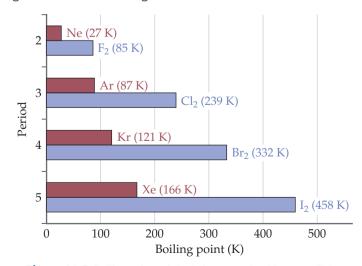

nucleus. At just that instant, the atom has an instantaneous dipole moment as shown in Figure 11.4(b). The motions of electrons in one atom influence the motions of electrons in its neighbors. The instantaneous dipole on one atom can induce an instantaneous dipole on an adjacent atom, causing the atoms to be attracted to each other as shown in Figure 11.4(c). This attractive interaction is called the **dispersion force** (or the *London dispersion force* in some texts). It is significant only when molecules are very close together.

The strength of the dispersion force depends on the ease with which the charge distribution in a molecule can be distorted to induce an instantaneous dipole. The ease with which the charge distribution is distorted is called the molecule's **polarizability**. We can think of the polarizability of a molecule as a measure of the "squashiness" of its electron cloud: The greater the polarizability, the more easily the electron cloud can be distorted to give an instantaneous dipole. Therefore, more polarizable molecules have larger dispersion forces.

In general, polarizability increases as the number of electrons in an atom or molecule increases. The strength of dispersion forces therefore tends to increase with increasing atomic or molecular size. Because molecular size and mass generally parallel each other, dispersion forces tend to increase in strength with increasing molecular weight. We can see this in the boiling points of the halogens and noble gases (> Figure 11.5), where dispersion forces are the only intermolecular forces at work. In both families the molecular

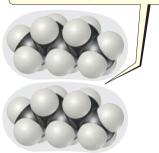

GO FIGURE

Why is the boiling point of the halogen in each period greater than the noble gas?

▲ Figure 11.5 Boiling points of the halogens and noble gases. This plot shows how the boiling points increase due to stronger dispersion forces as the molecular weight increases.

Linear molecule—larger surface area enhances intermolecular contact and increases dispersion force

n-Pentane (C_5H_{12}) bp = 309.4 K

Spherical molecule—smaller surface area diminishes intermolecular contact and decreases dispersion force

Neopentane (C_5H_{12}) bp = 282.7 K

▲ Figure 11.6 Molecular shape affects intermolecular attraction. Molecules of *n*-pentane make more contact with each other than do neopentane molecules. Thus, *n*-pentane has stronger intermolecular attractive forces and therefore a higher boiling point.

weight increases on moving down the periodic table. The higher molecular weights translate into stronger dispersion forces, which in turn lead to higher boiling points.

Give It Some Thought

List the substances CCI₄, CBr₄, and CH₄ in order of increasing boiling point.

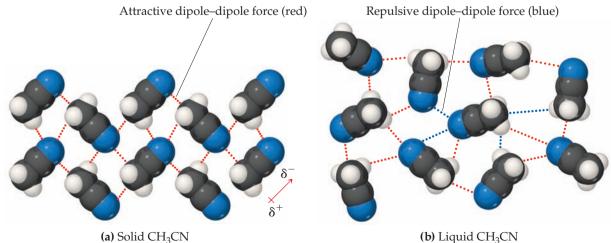

Molecular shape also influences the magnitudes of dispersion forces. For example, n-pentane* and neopentane (\P Figure 11.6) have the same molecular formula (C_5H_{12}), yet the boiling point of n-pentane is about 27 K higher than that of neopentane. The difference can be traced to the different shapes of the two molecules. Intermolecular attraction is greater for n-pentane because the molecules can come in contact over the entire length of the long, somewhat cylindrical molecules. Less contact is possible between the more compact and nearly spherical neopentane molecules.

Dipole-Dipole Forces

The presence of a permanent dipole moment in polar molecules gives rise to **dipole-dipole forces**. These forces originate from electrostatic attractions between the partially positive end of one molecule and the partially negative end of a neighboring molecule. Repulsions can also occur when the positive (or negative) ends of two molecules are in close proximity. Dipole-dipole forces are effective only when molecules are very close together.

To see the effect of dipole–dipole forces, we compare the boiling points of two compounds of similar molecular weight: acetonitrile (CH₃CN, MW 41 amu, bp 355 K) and propane (CH₃CH₂CH₃, MW 44 amu, bp 231 K). Acetonitrile is a polar molecule, with a dipole moment of 3.9 D, so dipole–dipole forces are present. However, propane is essentially nonpolar, which means that dipole–dipole forces are absent. Because acetonitrile and propane have similar molecular weights, dispersion forces are similar for these two molecules. Therefore, the higher boiling point of acetonitrile can be attributed to dipole–dipole forces.

To better understand these forces, consider how CH_3CN molecules pack together in the solid and liquid states. In the solid [\blacktriangledown Figure 11.7(a)], the molecules are arranged with the negatively charged nitrogen end of each molecule close to the positively charged — CH_3 ends of its neighbors. In the liquid [Figure 11.7(b)], the molecules are free to move with respect to one another, and their arrangement becomes more disordered. This means that, at any given instant, both attractive and repulsive dipole–dipole interactions are present. However, not only are there more attractive interactions than repulsive ones, but also molecules that are attracting each other spend more time near each other than do molecules that are repelling each other. The overall effect is a net attraction strong enough to keep the molecules in liquid CH_3CN from moving apart to form a gas.

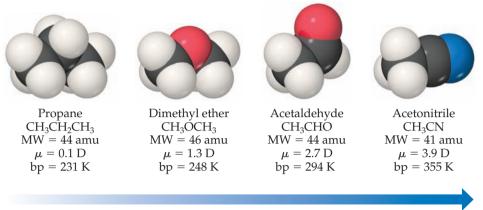

▲ Figure 11.7 Dipole–dipole interactions. The dipole–dipole interactions in (a) crystalline CH₃CN and (b) liquid CH₃CN.

^{*}The n in n-pentane is an abbreviation for the word normal. A normal hydrocarbon is one in which the carbon atoms are arranged in a straight chain. ∞ (Section 2.9)

GO FIGURE

Moving from left to right, do the dispersion forces get stronger, get weaker, or stay roughly the same in the molecules shown here?

Increasing polarity Increasing strength of dipole-dipole forces

▲ Figure 11.8 Molecular weights, dipole moments, and boiling points of several simple organic substances.

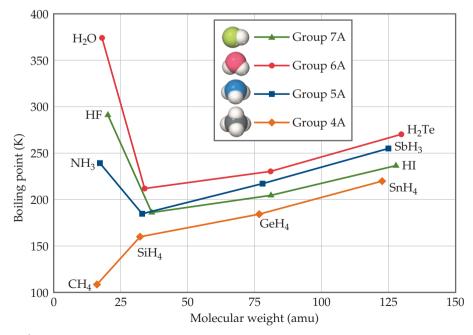

For molecules of approximately equal mass and size, the strength of intermolecular attractions increases with increasing polarity, a trend we see in ▲ Figure 11.8. Notice how the boiling point increases as the dipole moment increases.

Hydrogen Bonding

▼ Figure 11.9 shows the boiling points of the binary compounds that form between hydrogen and the elements in groups 4A through 7A. The boiling points of the compounds containing group 4A elements (CH₄ through SnH₄, all nonpolar)

GO FIGURE

Why is the boiling point of SiH₄ higher than that of CH₄?

GO FIGURE

To form a hydrogen bond, what must the non-hydrogen atom (N, O, or F) involved in the bond possess?

$$H-\ddot{F}:\cdotsH-\ddot{F}:$$

▲ Figure 11.10 Hydrogen bonding.

Hydrogen bonding can occur when an H atom is bonded to an N, O, or F atom.

increase systematically moving down the group. This is the expected trend because polarizability and, hence, dispersion forces generally increase as molecular weight increases. The heavier members of groups 5A, 6A, and 7A follow the same trend, but NH₃, H₂O, and HF have boiling points that are much higher than expected. In fact, these three compounds also have many other characteristics that distinguish them from other substances of similar molecular weight and polarity. For example, water has a high melting point, a high specific heat, and a high heat of vaporization. Each of these properties indicates that the intermolecular forces are abnormally strong.

The strong intermolecular attractions in HF, H₂O, and NH₃ result from hydrogen bonding. A hydrogen bond is an attraction between a hydrogen atom attached to a highly electronegative atom (usually F, O, or N) and a nearby small electronegative atom in another molecule or chemical group. Thus, H-F, H-O, or H-N bonds in one molecule can form hydrogen bonds with an F, O, or N atom in another molecule. Several examples of hydrogen bonds are shown in **▼ Figure 11.10**, including the hydrogen bond that exists between the H atom in an H₂O molecule and the O atom of an adjacent H₂O molecule. Notice in each case that the H atom in the hydrogen bond interacts with a nonbonding electron pair.

Hydrogen bonds can be considered a special type of dipole-dipole attraction. Because N, O, and F are so electronegative, a bond between hydrogen and any of these elements is quite polar, with hydrogen at the positive end (remember the + on the righthand side of the dipole symbol represents the positive end of the dipole):

$$\overset{\longleftarrow}{\longleftarrow}$$
 $\overset{\longleftarrow}{\longleftarrow}$ $\overset{\longleftarrow}{\longleftarrow}$ $\overset{\longleftarrow}{\longleftarrow}$ $\overset{\longleftarrow}{\longleftarrow}$ $\overset{\longleftarrow}{\longleftarrow}$

The hydrogen atom has no inner electrons. Thus, the positive side of the dipole has the concentrated charge of the nearly bare hydrogen nucleus. This positive charge is attracted to the negative charge of an electronegative atom in a nearby molecule. Because the electron-poor hydrogen is so small, it can approach an electronegative atom very closely and, thus, interact strongly with it.

SAMPLE EXERCISE 11.1 Identifying Substances That Can Form Hydrogen Bonds

In which of these substances is hydrogen bonding likely to play an important role in determining physical properties: methane (CH₄), hydrazine (H₂NNH₂), methyl fluoride (CH₃F), hydrogen sulfide (H₂S)?

SOLUTION

Analyze We are given the chemical formulas of four compounds and asked to predict whether they can participate in hydrogen bonding. All the compounds contain H, but hydrogen bonding usually occurs only when the hydrogen is covalently bonded to N, O, or F.

Plan We analyze each formula to see if it contains N, O, or F directly bonded to H. There also needs to be a nonbonding pair of electrons on an electronegative atom (usually N, O, or F) in a nearby molecule, which can be revealed by drawing the Lewis structure for the molecule.

Solve The foregoing criteria eliminate CH₄ and H₂S, which do not contain H bonded to N, O, or F. They also eliminate CH₃F, whose Lewis structure shows a central C atom surrounded by three H atoms and an F atom. (Carbon always forms four bonds, whereas hydrogen and fluorine form one each.) Because the molecule contains a C—F

bond and not an H—F bond, it does not form hydrogen bonds. In H₂NNH₂, however, we find N—H bonds, and the Lewis structure shows a nonbonding pair of electrons on each N atom, telling us hydrogen bonds can exist between the molecules:

Check Although we can generally identify substances that participate in hydrogen bonding based on their containing N, O, or F covalently bonded to H, drawing the Lewis structure for the interaction provides a way to check the prediction.

Practice Exercise 1

Which of the following substances is most likely to be a liquid at room temperature?

(a) Formaldehyde, H₂CO; (b) fluoromethane, CH₃F; (c) hydrogen cyanide, HCN; (d) hydrogen peroxide, H₂O₂; (e) hydrogen sulfide, H2S.

Practice Exercise 2

In which of these substances is significant hydrogen bonding possible: methylene chloride (CH₂Cl₂), phosphine (PH₃), chloramine (NH_2Cl) , acetone (CH_3COCH_3) ?

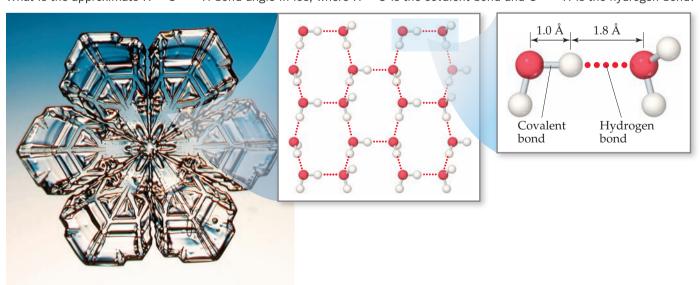

The energies of hydrogen bonds vary from about 5 to 25 kJ/mol, although there are isolated examples of hydrogen bond energies close to 100 kJ/mol. Thus, hydrogen bonds are typically much weaker than covalent bonds, which have bond enthalpies of 150-1100 kJ/mol (see Table 8.4). Nevertheless, because hydrogen bonds are generally stronger than dipole-dipole or dispersion forces, they play important roles in many chemical systems, including those of biological significance. For example, hydrogen bonds help stabilize the structures of proteins and are also responsible for the way that DNA is able to carry genetic information.

One remarkable consequence of hydrogen bonding is seen in the densities of ice and liquid water. In most substances the molecules in the solid are more densely packed than those in the liquid, making the solid phase denser than the liquid phase. By contrast, the density of ice at 0 °C (0.917 g/mL) is less than that of liquid water at $0 \,^{\circ}\text{C} (1.00 \,\text{g/mL})$, so ice floats on liquid water.

The lower density of ice can be understood in terms of hydrogen bonding. In ice, the H₂O molecules assume the ordered, open arrangement shown in ▼ Figure 11.11. This arrangement optimizes hydrogen bonding between molecules, with each H₂O molecule forming hydrogen bonds to four neighboring H₂O molecules. These hydrogen bonds, however, create the cavities seen in the middle image of Figure 11.11. When ice melts, the motions of the molecules cause the structure to collapse. The hydrogen bonding in the liquid is more random than that in the solid but is strong enough to hold the molecules close together. Consequently, liquid water has a denser structure than ice, meaning that a given mass of water occupies a smaller volume than the same mass of ice.

A GO FIGURE

What is the approximate $H - O \cdots H$ bond angle in ice, where H - O is the covalent bond and $O \cdots H$ is the hydrogen bond?

▲ Figure 11.11 Hydrogen bonding in ice. The empty channels in the structure of ice make water less dense as a solid than as a liquid.

▲ Figure 11.12 Expansion of water upon freezing.

The expansion of water upon freezing (Figure 11.12) is responsible for many phenomena we take for granted. It causes icebergs to float and water pipes to burst in cold weather. The lower density of ice compared to liquid water also profoundly affects life on Earth. Because ice floats, it covers the top of the water when a lake freezes, thereby insulating the water. If ice were denser than water, ice forming at the top of a lake would sink to the bottom, and the lake could freeze solid. Most aquatic life could not survive under these conditions.

Give It Some Thought

What major type of attractive interaction must be overcome for water to evaporate?

Ion-Dipole Forces

An **ion-dipole force** exists between an ion and a polar molecule (▼ **Figure 11.13**). Cations are attracted to the negative end of a dipole, and anions are attracted to the positive end. The magnitude of the attraction increases as either the ionic charge or the magnitude of the dipole moment increases. Ion-dipole forces are especially important for solutions of ionic substances in polar liquids, such as a solution of NaCl in water. ⇔ (Section 4.1)

Give It Some Thought

In which mixture do you expect to find ion–dipole forces between solute and solvent? CH_3OH in water or $Ca(NO_3)_2$ in water.

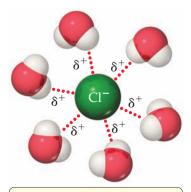

Comparing Intermolecular Forces

We can identify the intermolecular forces operative in a substance by considering its composition and structure. *Dispersion forces are found in all substances*. The strength of these attractive forces increases with increasing molecular weight and depends on molecular shapes. With polar molecules dipole–dipole forces are also operative, but these forces often make a smaller contribution to the total intermolecular attraction than do dispersion forces. For example, in liquid HCl, dispersion forces are estimated to account for more than 80% of the total attraction between molecules, while dipole–dipole attractions account for the rest. Hydrogen bonds, when present, make an important contribution to the total intermolecular interaction.

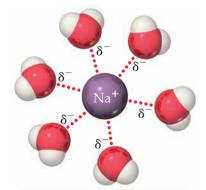

GO FIGURE

Why does the O side of H₂O point toward the Na⁺ ion?

Positive ends of polar molecules are oriented toward negatively charged anion

Negative ends of polar molecules are oriented toward positively charged cation

In general, the energies associated with dispersion forces are $0.1-30 \, kJ/mol$. The wide range reflects the wide range in polarizabilities of molecules. By comparison, the energies associated with dipole–dipole forces and hydrogen bonds are approximately $2-15 \, kJ/mol$ and $10-40 \, kJ/mol$, respectively. Ion–dipole forces tend to be stronger than the aforementioned intermolecular forces, with energies typically exceeding $50 \, kJ/mol$. All these interactions are considerably weaker than covalent and ionic bonds, which have energies that are hundreds of kilojoules per mole.

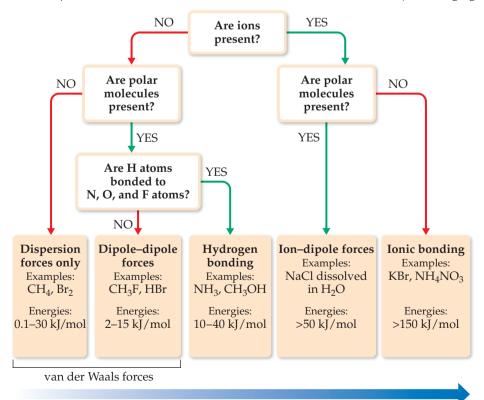

When comparing the relative strengths of intermolecular attractions, consider these generalizations:

- 1. When the molecules of two substances have comparable molecular weights and shapes, dispersion forces are approximately equal in the two substances. Differences in the magnitudes of the intermolecular forces are due to differences in the strengths of dipole–dipole attractions. The intermolecular forces get stronger as molecule polarity increases, with those molecules capable of hydrogen bonding having the strongest interactions.
- 2. When the molecules of two substances differ widely in molecular weights, and there is no hydrogen bonding, dispersion forces tend to determine which substance has the stronger intermolecular attractions. Intermolecular attractive forces are generally higher in the substance with higher molecular weight.
- ▼ Figure 11.14 presents a systematic way of identifying the intermolecular forces in a particular system.

It is important to realize that the effects of all these attractions are additive. For example, acetic acid, CH₃COOH, and 1-propanol, CH₃CH₂CH₂OH, have the same molecular weight, 60 amu, and both are capable of forming hydrogen bonds. However, a pair of acetic

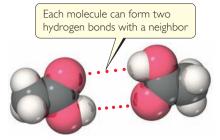

At which point in this flowchart would a distinction be made between SiH₄ and SiH₂Br₂?

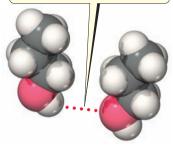

Increasing interaction strength

▲ Figure 11.14 Flowchart for determining intermolecular forces. Multiple types of intermolecular forces can be at work in a given substance or mixture. In particular, dispersion forces occur in all substances.

Acetic acid, CH₃COOH MW = 60 amubp = 391 K

Each molecule can form one hydrogen bond with a neighbor

1-Propanol, CH₃CH₂CH₂OH MW = 60 amubp = 370 K

▲ Figure 11.15 Hydrogen bonding in acetic acid and 1-propanol. The greater the number of hydrogen bonds possible, the more tightly the molecules are held together and, therefore, the higher the boiling point.

acid molecules can form two hydrogen bonds, whereas a pair of 1-propanol molecules can form only one (Figure 11.15). Hence, the boiling point of acetic acid is higher. These effects can be important, especially for very large polar molecules such as proteins, which have multiple dipoles over their surfaces. These molecules can be held together in solution to a surprisingly high degree due to the presence of multiple dipole-dipole attractions.

SAMPLE

EXERCISE 11.2 Predicting Types and Relative Strengths of Intermolecular Attractions

List the substances BaCl₂, H₂, CO, HF, and Ne in order of increasing boiling point.

SOLUTION

Analyze We need to assess the intermolecular forces in these substances and use that information to determine the relative boiling points.

Plan The boiling point depends in part on the attractive forces in each substance. We need to order these substances according to the relative strengths of the different kinds of intermolecular attractions.

Solve The attractive forces are stronger for ionic substances than for molecular ones, so BaCl₂ should have the highest boiling point. The intermolecular forces of the remaining substances depend on molecular weight, polarity, and hydrogen bonding. The molecular weights are H₂, 2; CO, 28; HF, 20; and Ne, 20. The boiling point of H₂ should be the lowest because it is nonpolar and has the lowest molecular weight. The molecular weights of CO, HF, and Ne are similar. Because HF can hydrogenbond, it should have the highest boiling point of the three. Next is CO, which is slightly polar and has the highest molecular weight. Finally, Ne, which is nonpolar, should have the lowest boiling point of these three. The predicted order of boiling points is, therefore,

$$H_2 < Ne < CO < HF < BaCl_2$$

Check The boiling points reported in the literature are H₂, 20 K; Ne, 27 K; CO, 83 K; HF, 293 K; and BaCl₂, 1813 K—in agreement with our predictions.

Practice Exercise 1

List the substances Ar, Cl₂, CH₄, and CH₃COOH in order of increasing strength of intermolecular attractions.

(a) $CH_4 < Ar < CH_3COOH < Cl_2$

(b) $Cl_2 < CH_3COOH < Ar < CH_4$

(c) $CH_4 < Ar < Cl_2 < CH_3COOH$

(d) $CH_3COOH < Cl_2 < Ar < CH_4$

(e) $Ar < Cl_2 < CH_4 < CH_3COOH$

Practice Exercise 2

(a) Identify the intermolecular attractions present in the following substances and (b) select the substance with the highest boiling point: CH₃CH₃, CH₃OH, and CH₃CH₂OH.

Chemistry Put to Work

Ionic Liquids

The strong electrostatic attractions between cations and anions explain why most ionic compounds are solids at room temperature, with high melting and boiling points. However, the melting point of an ionic compound can

be low if the ionic charges are not too high and the cation-anion distance is sufficiently large. For example, the melting point of NH₄NO₃, where both cation and anion are larger polyatomic ions, is 170 °C. If the ammonium cation is replaced by the even larger ethylammonium cation, CH₃CH₂NH₃⁺, the melting point drops to 12 °C, making ethylammonium nitrate a liquid at room temperature. Ethylammonium nitrate is an example of an ionic liquid: a salt that is a liquid at room temperature.

Not only is CH₃CH₂NH₃⁺ larger than NH₄, but also it is less symmetric. In general, the larger and more irregularly shaped the ions in an ionic substance, the better the chances of forming an ionic liquid. Among the cations that form ionic liquids, one of the most widely used is the 1-butyl-3methylimidazolium cation (abbreviated bmim⁺, ▼ Figure 11.16 and ▶ Table 11.4), which has two arms of different lengths coming off a

▲ Figure 11.16 Representative ions found in ionic liquids.

Table 11.4 Melting Point and Decomposition Temperature of Four 1-Butyl-3-Methylimidazolium (bmim⁺) Salts

Cation	Anion	Melting Point (°C)	Decomposition Temperature (°C)
bmim ⁺	Cl ⁻	41	254
$bmim^+$	I^-	-72	265
$bmim^+$	PF_6^{-}	10	349
bmim ⁺	$\mathrm{BF_4}^-$	-81	403

five-atom central ring. This feature gives bmim⁺ an irregular shape, which makes it difficult for the molecules to pack together in a solid.

Common anions found in ionic liquids include the PF_6^- , BF_4^- , and halide ions.

Ionic liquids have many useful properties. Unlike most molecular liquids, they are nonvolatile (that is, they don't evaporate readily) and nonflammable. They tend to remain in the liquid state at temperatures up to about 400 °C. Most molecular substances are liquids only at much lower temperatures, 100 °C or less in most cases (see Table 11.3). Because ionic liquids are good solvents for a wide range of substances, ionic liquids can be used for a variety of reactions and separations. These properties make them attractive replacements for volatile organic solvents in many industrial processes. Relative to traditional organic solvents, ionic liquids offer the promise of reduced volumes, safer handling, and easier reuse, thereby reducing the environmental impact of industrial chemical processes.

11.3 | Select Properties of Liquids

The intermolecular attractions we have just discussed can help us understand many familiar properties of liquids. In this section we examine three: viscosity, surface tension, and capillary action.

Viscosity

Some liquids, such as molasses and motor oil, flow very slowly; others, such as water and gasoline, flow easily. The resistance of a liquid to flow is called **viscosity**. The greater a liquid's viscosity, the more slowly it flows. Viscosity can be measured by timing how long it takes a certain amount of the liquid to flow through a thin vertical tube (> Figure 11.17). Viscosity can also be determined by measuring the rate at which steel balls fall through the liquid. The balls fall more slowly as the viscosity increases.

Viscosity is related to the ease with which the molecules of the liquid can move relative to one another. It depends on the attractive forces between molecules and on whether the shapes and flexibility of the molecules are such that they tend to become entangled (for example, long molecules can become tangled like spaghetti). For a series of related compounds, viscosity increases with molecular weight, as illustrated in **Table 11.5**. The SI unit for viscosity is kg/m-s.

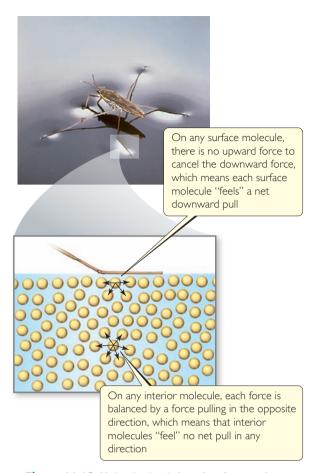

SAE 40 higher number higher viscosity slower pouring

SAE 10 lower number lower viscosity faster pouring

▲ Figure 11.17 Comparing viscosities. The Society of Automotive Engineers (SAE) has established a numeric scale to indicate motor-oil viscosity.

Table 11.5	Viccocities	of a	Sorios	of H	vdrocarbons	at 20	°C
Table 11.5	viscosities	or a	Series	OI II	varocarbons	at 20	<u>_</u>

Substance	Formula	Viscosity (kg/m-s)
Hexane	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	3.26×10^{-4}
Heptane	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	4.09×10^{-4}
Octane	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	5.42×10^{-4}
Nonane	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	7.11×10^{-4}
Decane	CH ₃ CH ₂ CH ₃	1.42×10^{-3}

▲ Figure 11.18 Molecular-level view of surface tension. The high surface tension of water keeps the water strider from sinking.

For any given substance, viscosity decreases with increasing temperature. Octane, for example, has a viscosity of $7.06 \times 10^{-4} \, \text{kg/m-s}$ at 0 °C and $4.33 \times 10^{-4} \, \text{kg/m-s}$ at 40 °C. At higher temperatures the greater average kinetic energy of the molecules overcomes the attractive forces between molecules.

Surface Tension

The surface of water behaves almost as if it had an elastic skin, as evidenced by the ability of certain insects to "walk" on water. This behavior is due to an imbalance of intermolecular forces at the surface of the liquid. As shown in ◀ Figure 11.18, molecules in the interior are attracted equally in all directions, but those at the surface experience a net inward force. This net force tends to pull surface molecules toward the interior, thereby reducing the surface area and making the molecules at the surface pack closely together.

Because spheres have the smallest surface area for their volume, water droplets assume an almost spherical shape. This explains the tendency of water to "bead up" when it contacts a surface made of nonpolar molecules, like a lotus leaf or a newly waxed car.

A measure of the net inward force that must be overcome to expand the surface area of a liquid is given by its surface tension. Surface tension is the energy required to increase the surface area of a liquid by a unit amount. For example, the surface tension of water at $20\,^{\circ}\text{C}$ is $7.29\times10^{-2}\,\text{J/m}^2$, which means that an energy of $7.29\times10^{-2}\,\text{J}$ must be supplied to increase the surface area of a given amount of water by $1\,\text{m}^2$. Water has a high surface tension because of its strong hydrogen bonds. The surface tension of mercury is even higher $(4.6\times10^{-1}\,\text{J/m}^2)$ because of even stronger metallic bonds between the atoms of mercury.

Give It Some Thought

How do viscosity and surface tension change?

- (a) as temperature increases
- (b) as intermolecular forces of attraction become stronger

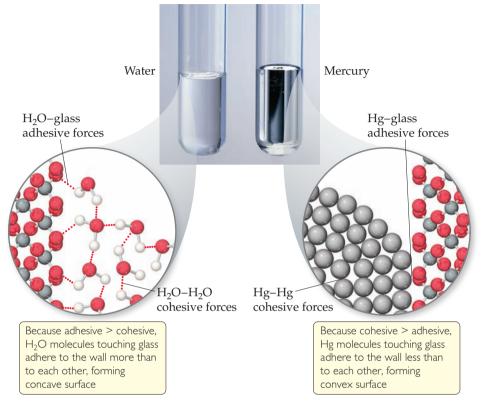

Capillary Action

Intermolecular forces that bind similar molecules to one another, such as the hydrogen bonding in water, are called *cohesive forces*. Intermolecular forces that bind a substance to a surface are called *adhesive forces*. Water placed in a glass tube adheres to the glass because the adhesive forces between the water and the glass are greater than the cohesive forces between water molecules. The curved surface, or *meniscus*, of the water is therefore U-shaped (▶ Figure 11.19). For mercury, however, the situation is different. Mercury atoms can form bonds with one another but not with the glass. As a result the cohesive forces are much greater than the adhesive forces and the meniscus is shaped like an inverted U.

When a small-diameter glass tube, or capillary, is placed in water, water rises in the tube. The rise of liquids up very narrow tubes is called **capillary action**. The adhesive forces between the liquid and the walls of the tube tend to increase the surface area of the liquid. The surface tension of the liquid tends to reduce the area, thereby pulling the liquid up the tube. The liquid climbs until the force of gravity on the liquid balances the adhesive and cohesive forces. Capillary action is widespread. For example, towels absorb liquid and "stay-dry" synthetic fabrics move sweat away from the skin by capillary action. Capillary action also plays a role in moving water and dissolved nutrients upward through plants.

A GO FIGURE

If the inside surface of each tube were coated with wax, would the general shape of the water meniscus change? Would the general shape of the mercury meniscus change?

▲ Figure 11.19 Meniscus shapes for water and mercury in glass tubes.

11.4 | Phase Changes

Liquid water left uncovered in a glass eventually evaporates. An ice cube left in a warm room quickly melts. Solid CO₂ (sold as a product called dry ice) sublimes at room temperature; that is, it changes directly from solid to gas. In general, each state of matter—solid, liquid, gas can transform into either of the other two states. ▶ Figure 11.20 shows the names associated with these transformations, which are called either phase changes or changes of state.

Energy Changes Accompanying Phase Changes

Every phase change is accompanied by a change in the energy of the system. In a solid, for example, the particles (molecules, ions, or atoms) are in more or less fixed positions with respect to one another and closely arranged to minimize the energy of the system. As the temperature of the solid increases, the particles vibrate about their equilibrium positions with increasing energetic motion. When the solid melts, the particles are freed to move relative to one another, which means their average kinetic energy increases.

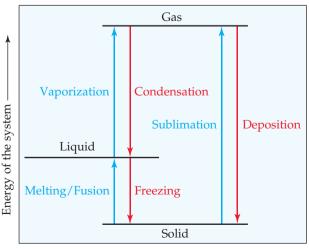

Melting is called (somewhat confusingly) fusion. The increased freedom of motion of the particles requires energy, measured by the **heat of fusion** or *enthalpy of fusion*, ΔH_{fus} . The heat of fusion of ice, for example, is 6.01 kJ/mol:

$$H_2O(s) \rightarrow H_2O(l)$$
 $\Delta H = 6.01 \text{ kJ}$

GO FIGURE

How is energy evolved in deposition related to those for condensation and freezing?

Endothermic process (energy added to substance)

Exothermic process (energy released from substance)

▲ Figure 11.20 Phase changes and the names associated with them.

As the temperature of the liquid increases, the particles move about more vigorously. The increased motion allows some particles to escape into the gas phase. As a result, the concentration of gas-phase particles above the liquid surface increases with temperature. These gas-phase particles exert a pressure called *vapor pressure*. We explore vapor pressure in Section 11.5. For now we just need to understand that vapor pressure increases with increasing temperature until it equals the external pressure above the liquid, typically atmospheric pressure. At this point the liquid boils—bubbles of the vapor form within the liquid. The energy required to cause the transition of a given quantity of the liquid to the vapor is called either the **heat of vaporization** or the *enthalpy of vaporization*, $\Delta H_{\rm vap}$. For water, the heat of vaporization is $40.7~{\rm kJ/mol.}$

$$H_2O(l) \longrightarrow H_2O(g)$$
 $\Delta H = 40.7 \text{ kJ}$

▼ Figure 11.21 shows $\Delta H_{\rm fus}$ and $\Delta H_{\rm vap}$ values for four substances. The values of $\Delta H_{\rm vap}$ tend to be larger than the values of $\Delta H_{\rm fus}$ because in the transition from liquid to gas, particles must essentially sever all their interparticle attractions, whereas in the transition from solid to liquid, many of these attractive interactions remain operative.

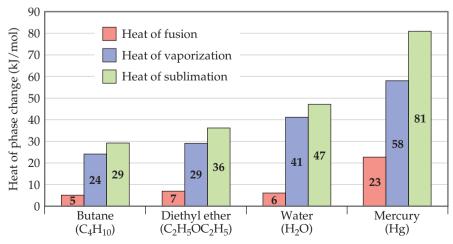

The particles of a solid can move directly into the gaseous state. The enthalpy change required for this transition is called the **heat of sublimation**, denoted ΔH_{sub} . As illustrated in Figure 11.20, ΔH_{sub} is the sum of ΔH_{fus} and ΔH_{vap} . Thus, ΔH_{sub} for water is approximately 47 kJ/mol.

Phase changes show up in important ways in our everyday experiences. When we use ice cubes to cool a drink, for instance, the heat of fusion of the ice cools the liquid. We feel cool when we step out of a swimming pool or a warm shower because the liquid water's heat of vaporization is drawn from our bodies as the water evaporates from our skin. Our bodies use this mechanism to regulate body temperature, especially when we exercise vigorously in warm weather. (Section 5.5) A refrigerator also relies on the cooling effects of vaporization. Its mechanism contains an enclosed gas that can be liquefied under pressure. The liquid absorbs heat as it subsequently evaporates, thereby cooling the interior of the refrigerator.

What happens to the heat absorbed when the liquid refrigerant vaporizes? According to the first law of thermodynamics ∞ (Section 5.2), this absorbed heat

A GO FIGURE

Is it possible to calculate the heat of sublimation for a substance given its heats of vaporization and fusion? If so, what is the relationship?

▲ Figure 11.21 Heats of fusion, vaporization, and sublimation.

must be released when the gas condenses to liquid. As this phase change occurs, the heat released is dissipated through cooling coils in the back of the refrigerator. Just as for a given substance the heat of condensation is equal in magnitude to the heat of vaporization and has the opposite sign, so too the heat of deposition for a given substance is exothermic to the same degree that the heat of sublimation is endothermic; the heat of freezing is exothermic to the same degree that the heat of fusion is endothermic (see Figure 11.20).

Give It Some Thought

What is the name of the phase change that occurs when ice left at room temperature changes to liquid water? Is this change exothermic or endothermic?

Heating Curves

When we heat an ice cube initially at -25 °C and 1 atm pressure, the temperature of the ice increases. As long as the temperature is below 0 °C, the ice cube remains in the solid state. When the temperature reaches 0 °C, the ice begins to melt. Because melting is an endothermic process, the heat we add at 0 °C is used to convert ice to liquid water, and the temperature remains constant until all the ice has melted. Once all the ice has melted, adding more heat causes the temperature of the liquid water to increase.

A graph of temperature versus amount of heat added is called a *heating curve*. ▶ Figure 11.22 shows the heating curve for transforming ice, $H_2O(s)$, initially at -25 °C to steam, $H_2O(g)$, at 125 °C. Heating the $H_2O(s)$ from -25 to 0 °C is represented by the line segment AB, and converting the $H_2O(s)$ at 0 °C to $H_2O(l)$ at 0 °C is the horizontal segment BC. Additional heat increases the temperature of the $H_2O(l)$ until the temperature reaches 100 °C (segment CD). The heat is then used to convert $H_2O(l)$ to $H_2O(g)$

at a constant temperature of 100 °C (segment *DE*) as the water boils. Once all the $H_2O(l)$ has been converted to $H_2O(g)$, adding heat increases the temperature of the $H_2O(g)$ (segment *EF*).

We can calculate the enthalpy change of the system for each segment of the heating curve. In segments AB, CD, and EF we are heating a single phase from one temperature to another. As we saw in Section 5.5, the amount of heat needed to raise the temperature of a substance is given by the product of the specific heat, mass, and temperature change (Equation 5.22). The greater the specific heat of a substance, the more heat we must add to accomplish a certain temperature increase. Because the specific heat of water is greater than that of ice, the slope of segment CD is less than that of segment AB. This lesser slope means the amount of heat we must add to a given mass of liquid water to achieve a 1 °C temperature change is greater than the amount we must add to achieve a 1 °C temperature change in the same mass of ice.

In segments BC and DE we are converting one phase to another at a constant temperature. The temperature remains constant during these phase changes because the added energy is used to overcome the attractive forces between molecules rather than to increase their average kinetic energy. For segment BC, the enthalpy change can be calculated by using ΔH_{fus} , and for segment DE we can use ΔH_{vap} .

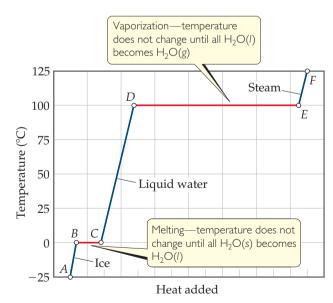

If we start with 1 mole of steam at 125 °C and cool it, we move right to left across Figure 11.22. We first lower the temperature of the $H_2O(g)$ $(F \longrightarrow E)$, then condense it $(E \longrightarrow D)$ to $H_2O(l)$, and so forth.

Sometimes as we remove heat from a liquid, we can temporarily cool it below its freezing point without forming a solid. This phenomenon, called supercooling, occurs when the heat is removed so rapidly that the molecules have no time to assume the

GO FIGURE

What process is occurring between points C and D?

▲ Figure 11.22 Heating curve for water. Changes that occur when 1.00 mol of H_2O is heated from $H_2O(s)$ at -25 °C to $H_2O(g)$ at 125 °C at a constant pressure of 1 atm. Even though heat is being added continuously, the system temperature does not change during the two phase changes (red lines).

ordered structure of a solid. A supercooled liquid is unstable; particles of dust entering the solution or gentle stirring is often sufficient to cause the substance to solidify quickly.

SAMPLE EXERCISE 11.3 Calculating ΔH for Temperature and Phase Changes

Calculate the enthalpy change upon converting 1.00 mol of ice at $-25\,^{\circ}\text{C}$ to steam at 125 $^{\circ}\text{C}$ under a constant pressure of 1 atm. The specific heats of ice, liquid water, and steam are 2.03, 4.18,

and 1.84 J/g-K, respectively. For H₂O, $\Delta H_{\rm fus}=6.01$ kJ/mol and $\Delta H_{\rm vap}=40.67$ kJ/mol.

SOLUTION

Analyze Our goal is to calculate the total heat required to convert 1 mol of ice at -25 °C to steam at 125 °C.

Plan We can calculate the enthalpy change for each segment and then sum them to get the total enthalpy change (Hess's law, Section 5.6).

Solve For segment AB in Figure 11.22, we are adding enough heat to ice to increase its temperature by 25 °C. A temperature change of 25 °C is the same as a temperature change of 25 K, so we can use the specific heat of ice to calculate the enthalpy change during this process:

For segment BC in Figure 11.22, in which we convert ice to water at 0 °C, we can use the molar enthalpy of fusion directly:

The enthalpy changes for segments *CD*, *DE*, and *EF* can be calculated in similar fashion:

The total enthalpy change is the sum of the changes of the individual steps:

Check The components of the total enthalpy change are reasonable relative to the horizontal lengths (heat added) of the segments in Figure 11.22. Notice that the largest component is the heat of vaporization.

Practice Exercise 1

What information about water is needed to calculate the enthalpy change for converting 1 mol $H_2O(g)$ at 100 °C to $H_2O(l)$ at 80 °C? (a) Heat of fusion, (b) heat of vaporization, (c) heat of

AB: $\Delta H = (1.00 \text{ mol})(18.0 \text{ g/mol})(2.03 \text{ J/g-K})(25 \text{ K}) = 914 \text{ J} = 0.91 \text{ kJ}$

BC: $\Delta H = (1.00 \text{ mol})(6.01 \text{ kJ/mol}) = 6.01 \text{ kJ}$

CD: $\Delta H = (1.00 \text{ mol})(18.0 \text{ g/mol})(4.18 \text{ J/g-K})(100 \text{ K}) = 7520 \text{ J} = 7.52 \text{ kJ}$

 $DE: \Delta H = (1.00 \text{ mol})(40.67 \text{ kJ/mol}) = 40.7 \text{ kJ}$

EF: $\Delta H = (1.00 \text{ mol})(18.0 \text{ g/mol})(1.84 \text{ J/g-K})(25 \text{ K}) = 830 \text{ J} = 0.83 \text{ kJ}$

 $\Delta H = 0.91 \text{ kJ} + 6.01 \text{ kJ} + 7.52 \text{ kJ} + 40.7 \text{ kJ} + 0.83 \text{ kJ} = 56.0 \text{ kJ}$

vaporization and specific heat of $H_2O(g)$, (**d**) heat of vaporization and specific heat of $H_2O(l)$, (**e**) heat of fusion and specific heat of $H_2O(l)$.

Practice Exercise 2

What is the enthalpy change during the process in which 100.0 g of water at 50.0 °C is cooled to ice at -30.0 °C? (Use the specific heats and enthalpies for phase changes given in Sample Exercise 11.3.)

Critical Temperature and Pressure

A gas normally liquefies at some point when pressure is applied. Suppose we have a cylinder fitted with a piston and the cylinder contains water vapor at 100 °C. If we increase the pressure on the water vapor, liquid water will form when the pressure is 760 torr. However, if the temperature is 110 °C, the liquid phase does not form until the pressure is 1075 torr. At 374 °C the liquid phase forms only at 1.655×10^5 torr (217.7 atm). Above this temperature no amount of pressure causes a distinct liquid phase to form. Instead, as pressure increases, the gas becomes steadily more compressed. The highest temperature at which a distinct liquid phase can form is called the **critical temperature**. The **critical pressure** is the pressure required to bring about liquefaction at this critical temperature.

The critical temperature is the highest temperature at which a liquid can exist. Above the critical temperature, the kinetic energies of the molecules are greater than the attractive forces that lead to the liquid state regardless of how much the substance

Substance	Critical Temperature (K)	Critical Pressure (atm)
Nitrogen, N ₂	126.1	33.5
Argon, Ar	150.9	48.0
Oxygen, O ₂	154.4	49.7
Methane, CH ₄	190.0	45.4
Carbon dioxide, CO ₂	304.3	73.0
Phosphine, PH ₃	324.4	64.5
Propane, CH ₃ CH ₂ CH ₃	370.0	42.0
Hydrogen sulfide, H ₂ S	373.5	88.9
Ammonia, NH ₃	405.6	111.5
Water, H ₂ O	647.6	217.7

is compressed to bring the molecules closer together. *The greater the intermolecular forces, the higher the critical temperature of a substance.*

Several critical temperatures and pressures are listed in **A Table 11.6**. Notice that nonpolar, low-molecular-weight substances, which have weak intermolecular attractions, have lower critical temperatures and pressures than substances that are polar or of higher molecular weight. Notice also that water and ammonia have exceptionally high critical temperatures and pressures as a consequence of strong intermolecular hydrogen-bonding forces.

Give It Some Thought

Why are the critical temperature and pressure for H_2O so much higher than those for H_2S , a related substance (Table 11.6)?

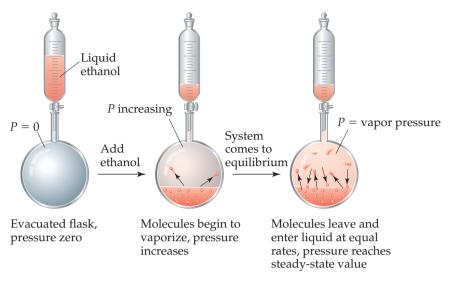

Because they provide information about the conditions under which gases liquefy, critical temperatures and pressures are often of considerable importance to engineers and other people working with gases. Sometimes we want to liquefy a gas; other times we want to avoid liquefying it. It is useless to try to liquefy a gas by applying pressure if the gas is above its critical temperature. For example, O_2 has a critical temperature of 154.4 K. It must be cooled below this temperature before it can be liquefied by pressure. In contrast, ammonia has a critical temperature of 405.6 K. Thus, it can be liquefied at room temperature (approximately 295 K) by applying sufficient pressure.

When the temperature exceeds the critical temperature and the pressure exceeds the critical pressure, the liquid and gas phases are indistinguishable from each other, and the substance is in a state called a **supercritical fluid**. A supercritical fluid expands to fill its container (like a gas), but the molecules are still quite closely spaced (like a liquid).

Like liquids, supercritical fluids can behave as solvents dissolving a wide range of substances. Using *supercritical fluid extraction*, the components of mixtures can be separated from one another. Supercritical fluid extraction has been successfully used to separate complex mixtures in the chemical, food, pharmaceutical, and energy industries. Supercritical CO₂ is a popular choice because it is relatively inexpensive and there are no problems associated with disposing of solvent, nor are there toxic residues resulting from the process.

11.5 | Vapor Pressure

Molecules can escape from the surface of a liquid into the gas phase by evaporation. Suppose we place a quantity of ethanol (CH_3CH_2OH) in an evacuated, closed container, as in Figure 11.23. The ethanol quickly begins to evaporate. As a result, the pressure exerted by the vapor in the space above the liquid increases. After a short time the pressure of the vapor attains a constant value, which we call the **vapor pressure**.

▲ Figure 11.23 Vapor pressure over a liquid.

At any instant, some of the ethanol molecules at the liquid surface possess sufficient kinetic energy to overcome the attractive forces of their neighbors and, therefore, escape into the gas phase. At any particular temperature, the movement of molecules from liquid phase to gas phase goes on continuously. As the number of gas-phase molecules increases, however, the probability increases that a molecule in the gas phase will strike the liquid surface and be recaptured by the liquid, as shown in the flask on the right in Figure 11.23. Eventually, the rate at which molecules return to the liquid equals the rate at which they escape. The number of molecules in the gas phase then reaches a steady value, and the pressure exerted by the vapor becomes constant.

The condition in which two opposing processes occur simultaneously at equal rates is called **dynamic equilibrium** (or simply *equilibrium*). Chemical equilibrium,

which we encountered in Section 4.1, is a kind of dynamic equilibrium in which the opposing processes are chemical reactions.

A liquid and its vapor are in dynamic equilibrium when evaporation and condensation occur at equal rates. It may appear that nothing is occurring at equilibrium because there is no net change in the system. In fact, though, a great deal is happening as molecules continuously pass from liquid state to gas state and from gas state to liquid state. The vapor pressure of a liquid is the pressure exerted by its vapor when the liquid and vapor are in dynamic equilibrium.

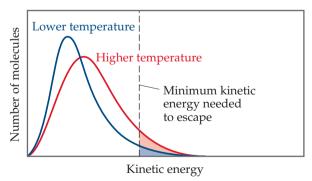

Volatility, Vapor Pressure, and Temperature

When vaporization occurs in an open container, as when water evaporates from a bowl, the vapor spreads away from the liquid. Little, if any, is recaptured at the surface of the liquid. Equilibrium never occurs, and the vapor continues to form until the liquid evaporates to dryness. Substances with high vapor pressure (such as gasoline) evaporate more quickly than substances with low vapor pressure (such as motor oil). Liquids that evaporate readily are said to be **volatile**.

Hot water evaporates more quickly than cold water because vapor pressure increases with increasing temperature. To see why this statement is true, we begin with the fact that the molecules of a liquid move at various speeds. ◀ Figure 11.24 shows the distribution of kinetic energies of the molecules at the surface of a liquid at two temperatures. (The curves are like those shown for gases in Section 10.7.) As the temperature is increased, the molecules move more energetically and more of them can break free from their neighbors and enter the gas phase, increasing the vapor pressure.

As the temperature increases, does the rate of molecules escaping into the gas phase increase or decrease?

Blue area = number of molecules having enough energy to evaporate at lower temperature

Red + blue areas = number of molecules having enough energy to evaporate at higher temperature

▲ Figure 11.24 The effect of temperature on the distribution of kinetic energies in a liquid.

▶ Figure 11.25 depicts the variation in vapor pressure with temperature for four common substances that differ greatly in volatility. Note that the vapor pressure in all cases increases nonlinearly with increasing temperature. The weaker the intermolecular forces in the liquid, the more easily molecules can escape and, therefore, the higher the vapor pressure at a given temperature.

Give It Some Thought

Which compound do you think is more volatile at 25 °C: CCl₄ or CBr₄?

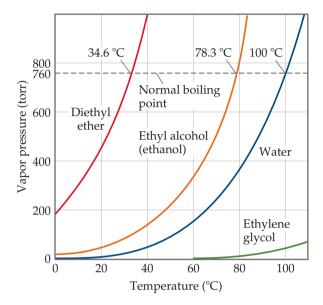

Vapor Pressure and Boiling Point

The **boiling point** of a liquid is the temperature at which its vapor pressure equals the external pressure, acting on the liquid surface. At this temperature, the thermal energy of the molecules is great enough for the molecules in the interior of the liquid to break free from their neighbors and enter the gas phase. As a result, bubbles of vapor form within the liquid. The boiling point increases as the external pressure increases. The boiling point of a liquid at 1 atm (760 torr) pressure is called its **normal boiling point**. From Figure 11.25 we see that the normal boiling point of water is 100 °C.

The time required to cook food in boiling water depends on the water temperature. In an open container, that temperature is 100 °C, but it is possible to boil at higher temperatures. Pressure cookers work by allowing steam to escape only when it exceeds a predetermined pressure; the pressure above the water can therefore increase above atmospheric pressure. The higher pressure causes the water to boil at a higher temperature, thereby allowing the food to get hotter and to cook more rapidly.

What is the vapor pressure of ethylene glycol at its normal boiling point?

▲ Figure 11.25 Vapor pressure for four liquids as a function of temperature.

The effect of pressure on boiling point also explains why it takes longer to cook food at high elevations than it does at sea level. The atmospheric pressure is lower at higher altitudes, so water boils at a temperature lower than 100 °C, and foods generally take longer to cook.

A Closer Look

The Clausius-Clapeyron Equation

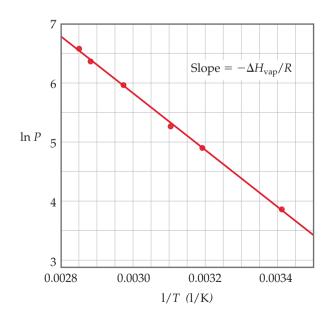

Notice that the plots in Figure 11.25 have a distinct shape: For each substance, the vapor–pressure curves sharply upward with increasing temperature. The relationship between vapor pressure and temperature is given by the *Clausius–Clapeyron equation*:

$$\ln P = \frac{-\Delta H_{\text{vap}}}{RT} + C \tag{11.1}$$

where P is the vapor pressure, T is the absolute temperature, R is the gas constant (8.314 J/mol-K), $\Delta H_{\rm vap}$ is the molar enthalpy of vaporization, and C is a constant. This equation predicts that a graph of $\ln P$ versus 1/T should give a straight line with a slope equal to $\Delta H_{\rm vap}/R$. Using this plot we can determine the enthalpy of vaporization of a substance:

$$\Delta H_{\rm vap} = -{\rm slope} \times R$$

As an example of how we use the Clausius–Clapeyron equation, the vapor-pressure data for ethanol shown in Figure 11.25 are graphed as $\ln P$ versus 1/T in \blacktriangleright Figure 11.26. The data lie on a straight line with a negative slope. We can use the slope to determine $\Delta H_{\rm vap}$ for ethanol, 38.56 kJ/mol. We can also extrapolate the line to obtain the vapor pressure of ethanol at temperatures above and below the temperature range for which we have data.

▲ Figure 11.26 The natural logarithm of vapor pressure versus 1/T for ethanol.

SAMPLE EXERCISE 11.4 Relating Boiling Point to Vapor Pressure

Use Figure 11.25 to estimate the boiling point of diethyl ether under an external pressure of 0.80 atm.

SOLUTION

Analyze We are asked to read a graph of vapor pressure versus temperature to determine the boiling point of a substance at a particular pressure. The boiling point is the temperature at which the vapor pressure is equal to the external pressure.

Plan We need to convert 0.80 atm to torr because that is the pressure scale on the graph. We estimate the location of that pressure on the graph, move horizontally to the vapor–pressure curve, and then drop vertically from the curve to estimate the temperature.

Solve The pressure equals (0.80 atm)(760 torr/atm) = 610 torr. From Figure 11.25 we see that the boiling point at this pressure is about 27 °C, which is close to room temperature.

Comment We can make a flask of diethyl ether boil at room temperature by using a vacuum pump to lower the pressure above the liquid to about 0.8 atm.

Practice Exercise 1

In the mountains, water in an open container will boil when

- (a) its critical temperature exceeds room temperature
- (b) its vapor pressure equals atmospheric pressure
- (c) its temperature is 100 °C
- (d) enough energy is supplied to break covalent bonds
- (e) none of these is correct

Practice Exercise 2

Use Figure 11.25 to determine the external pressure if ethanol boils at 60 $^{\circ}\text{C}.$

11.6 | Phase Diagrams

The equilibrium between a liquid and its vapor is not the only dynamic equilibrium that can exist between states of matter. Under appropriate conditions, a solid can be in equilibrium with its liquid or even with its vapor. The temperature at which solid and liquid phases coexist at equilibrium is the *melting point* of the solid or the *freezing point* of the liquid. Solids can also undergo evaporation and therefore possess a vapor pressure.

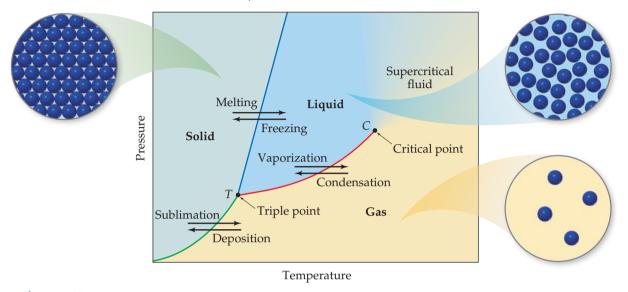

A **phase diagram** is a graphic way to summarize the conditions under which equilibria exist between the different states of matter. Such a diagram also allows us to predict which phase of a substance is present at any given temperature and pressure.

The phase diagram for any substance that can exist in all three phases of matter is shown in Figure 11.27. The diagram contains three important curves, each of which represents the temperature and pressure at which the various phases can coexist at equilibrium. The only substance present in the system is the one whose phase diagram is under consideration. The pressure shown in the diagram is either the pressure applied to the system or the pressure generated by the substance. The curves may be described as follows:

- 1. The red curve is the *vapor-pressure curve* of the liquid, representing equilibrium between the liquid and gas phases. The point on this curve where the vapor pressure is 1 atm is the normal boiling point of the substance. The vapor-pressure curve ends at the **critical point** (*C*), which corresponds to the critical temperature and critical pressure of the substance. At temperatures and pressures beyond the critical point, the liquid and gas phases are indistinguishable from each other, and the substance is a *supercritical fluid*.
- **2.** The green curve, the *sublimation curve*, separates the solid phase from the gas phase and represents the change in the vapor pressure of the solid as it sublimes at different temperatures. Each point on this curve is a condition of equilibrium between the solid and the gas.

A GO FIGURE

Imagine that the pressure on the solid phase in the figure is decreased at constant temperature. If the solid eventually sublimes, what must be true about the temperature?

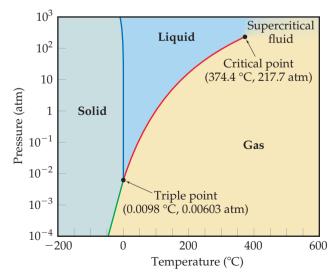

▲ Figure 11.27 Generic phase diagram for a pure substance. The green line is the sublimation curve, the blue line is the melting curve, and the red line is the vapor–pressure curve.

3. The blue curve, the *melting curve*, separates the solid phase from the liquid phase and represents the change in melting point of the solid with increasing pressure. Each point on this curve is an equilibrium between the solid and the liquid. This curve usually slopes slightly to the right as pressure increases because for most substances the solid form is denser than the liquid form. An increase in pressure usually favors the more compact solid phase; thus, higher temperatures are required to melt the solid at higher pressures. The melting point at 1 atm is the **normal melting point**.

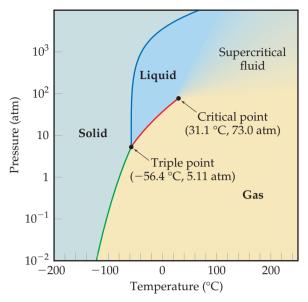

Point *T*, where the three curves intersect, is the **triple point**, and here all three phases are in equilibrium. Any other point on any of the three curves represents equilibrium between two phases. Any point on the diagram that does not fall on one of the curves corresponds to conditions under which only one phase is present. The gas phase, for example, is stable at low pressures and high temperatures, whereas the solid phase is stable at low temperatures and high pressures. Liquids are stable in the region between the other two.

The Phase Diagrams of H₂O and CO₂

▶ Figure 11.28 shows the phase diagram of H₂O. Because of the large range of pressures covered in the diagram, a logarithmic scale is used to represent pressure. The melting curve (blue line) of H₂O is atypical, slanting slightly to the left with increasing pressure, indicating that for water the melting point *decreases* with increasing pressure. This unusual behavior occurs because water is among the very few substances whose liquid form is more compact than its solid form, as we learned in Section 11.2.

ightharpoonup Figure 11.28 Phase diagram of H_2O . Note that a linear scale is used to represent temperature and a logarithmic scale to represent pressure.

▲ Figure 11.29 Phase diagram of CO₂. Note that a linear scale is used to represent temperature and a logarithmic scale to represent pressure.

If the pressure is held constant at 1 atm, it is possible to move from the solid to liquid to gaseous regions of the phase diagram by changing the temperature, as we expect from our everyday encounters with water. The triple point of H_2O falls at a relatively low pressure, 0.00603 atm. Below this pressure, liquid water is not stable and ice sublimes to water vapor on heating. This property of water is used to "freeze-dry" foods and beverages. The food or beverage is frozen to a temperature below 0 °C. Next it is placed in a low-pressure chamber (below 0.00603 atm) and then warmed so that the water sublimes, leaving behind dehydrated food or beverage.

The phase diagram for CO_2 is shown in \P Figure 11.29. The melting curve (blue line) behaves typically, slanting to the right with increasing pressure, telling us that the melting point of CO_2 increases with increasing pressure. Because the pressure at the triple point is relatively high, 5.11 atm, CO_2 does not exist as a liquid at 1 atm, which means that solid CO_2 does not melt when heated, but instead sublimes. Thus, CO_2 does not have a normal melting point; instead, it has a normal sublimation point, -78.5 °C. Because CO_2 sublimes rather than melts as it absorbs energy at ordinary pressures, solid CO_2 (dry ice) is a convenient coolant.

SAMPLE EXERCISE 11.5 Interpreting a Phase Diagram

Use the phase diagram for methane, CH_4 , shown in ∇ Figure 11.30 to answer the following questions. (a) What are the approximate temperature and pressure of the critical point? (b) What are the approximate temperature and pressure of the triple point? (c) Is methane a solid, liquid, or gas at 1 atm and 0 °C? (d) If solid methane at 1 atm is heated while the pressure is held constant, will it melt or sublime? (e) If methane at 1 atm and 0 °C is compressed until a phase change occurs, in which state is the methane when the compression is complete?

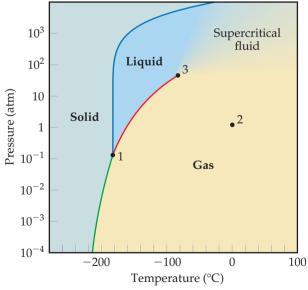

SOLUTION

Analyze We are asked to identify key features of the phase diagram and to use it to deduce what phase changes occur when specific pressure and temperature changes take place.

Plan We must identify the triple and critical points on the diagram and also identify which phase exists at specific temperatures and pressures.

Solve

- (a) The critical point is the point where the liquid, gaseous, and supercritical fluid phases coexist. It is marked point 3 in the phase diagram and located at approximately −80 °C and 50 atm.
- (b) The triple point is the point where the solid, liquid, and gaseous phases coexist. It is marked point 1 in the phase diagram and located at approximately $-180\,^{\circ}\text{C}$ and 0.1 atm.
- (c) The intersection of $0\,^{\circ}\text{C}$ and 1 atm is marked point 2 in the phase diagram. It is well within the gaseous region of the phase diagram.
- (d) If we start in the solid region at P=1 atm and move horizontally (this means we hold the pressure constant), we cross first into the liquid region, at $T\approx-180\,^{\circ}\mathrm{C}$, and then into the gaseous region, at $T\approx-160\,^{\circ}\mathrm{C}$. Therefore, solid methane melts when the pressure is 1 atm. (For methane to sublime, the pressure must be below the triple point pressure.)

▲ Figure 11.30 Phase diagram of CH₄. Note that a linear scale is used to represent temperature and a logarithmic scale to represent pressure.

(e) Moving vertically up from point 2, which is 1 atm and 0 $^{\circ}$ C, the first phase change we come to is from gas to supercritical fluid. This phase change happens when we exceed the critical pressure (\sim 50 atm).

Check The pressure and temperature at the critical point are higher than those at the triple point, which is expected. Methane is the principal component of natural gas. So it seems reasonable that it exists as a gas at 1 atm and 0 $^{\circ}$ C.

Practice Exercise 1

Based on the phase diagram for methane (Figure 11.30), what happens to methane as it is heated from -250 to 0 °C at a pressure of 10^{-2} atm?

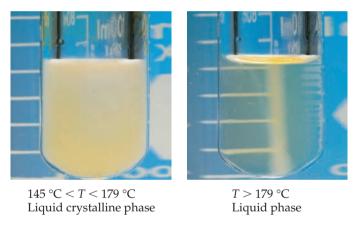

- (a) It sublimes at about -200 °C. (b) It melts at about -200 °C.
- (c) It boils at about -200 °C. (d) It condenses at about -200 °C.
- (e) It reaches the triple point at about -200 °C.

Practice Exercise 2

Use the phase diagram of methane to answer the following questions. (a) What is the normal boiling point of methane? (b) Over what pressure range does solid methane sublime? (c) Above what temperature does liquid methane not exist?

11.7 | Liquid Crystals

In 1888 Frederick Reinitzer, an Austrian botanist, discovered that the organic compound cholesteryl benzoate has an interesting and unusual property, shown in ▼ Figure 11.31. Solid cholesteryl benzoate melts at 145 °C, forming a viscous milky liquid; then at 179 °C the milky liquid becomes clear and remains that way at temperatures above 179 °C. When cooled, the clear liquid turns viscous and milky at 179 °C, and the milky liquid solidifies at 145 °C.

▲ Figure 11.31 Cholesteryl benzoate in its liquid and liquid crystalline states.

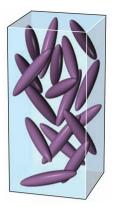

Reinitzer's work represents the first systematic report of what we call a **liquid crystal**, the term we use today for the viscous, milky state that some substances exhibit between the liquid and solid states.

This intermediate phase has some of the structure of solids and some of the freedom of motion of liquids. Because of the partial ordering, liquid crystals may be viscous and possess properties intermediate between those of solids and those of liquids. The region in which they exhibit these properties is marked by sharp transition temperatures, as in Reinitzer's sample.

Today liquid crystals are used as pressure and temperature sensors and as liquid crystals displays (LCDs) in such devices as digital watches, televisions, and computers. They can be used for these applications because the weak intermolecular forces that hold the molecules together in the liquid crystalline phase are easily affected by changes in temperature, pressure, and electric fields.

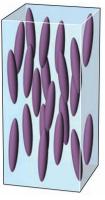

Types of Liquid Crystals

Substances that form liquid crystals are often composed of rod-shaped molecules that are somewhat rigid. In the liquid phase, these molecules are oriented randomly. In the liquid crystalline phase, by contrast, the molecules are arranged in specific patterns as

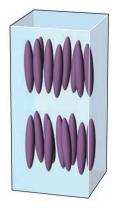

Liquid phase

Molecules arranged randomly

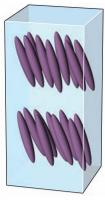

Nematic liquid crystalline phase

Long axes of molecules aligned, but ends are not aligned

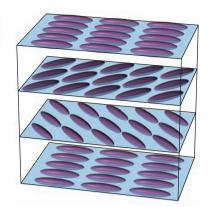

Smectic A liquid crystalline phase

Molecules aligned in layers, long axes of molecules perpendicular to layer planes

Smectic C liquid crystalline phase

Molecules aligned in layers, long axes of molecules inclined with respect to layer planes

Cholesteric liquid crystalline phase

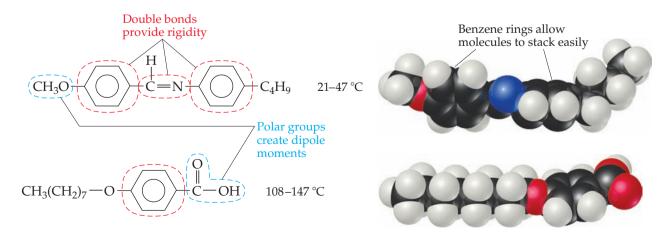

Molecules pack into layers, long axes of molecules in one layer rotated relative to the long axes in the layer above it

▲ Figure 11.32 Molecular order in nematic, smectic, and cholesteric liquid crystals. In the liquid phase of any substance, the molecules are arranged randomly, whereas in the liquid crystalline phases the molecules are arranged in a partially ordered way.

illustrated in ▲ Figure 11.32. Depending on the nature of the ordering, liquid crystals are classified as nematic, smectic A, smectic C, or cholesteric.

In a **nematic liquid crystal**, the molecules are aligned so that their long axes tend to point in the same direction but the ends are not aligned with one another. In **smectic A** and **smectic C liquid crystals**, the molecules maintain the long-axis alignment seen in nematic crystals, but in addition they pack into layers.

Two molecules that exhibit liquid crystalline phases are shown in ▼ Figure 11.33. The lengths of these molecules are much greater than their widths. The double bonds, including those in the benzene rings, add rigidity to the molecules, and the rings, because they are flat, help the molecules stack with one another. The polar —CH₃O and —COOH groups give rise to dipole–dipole interactions and promote alignment of the molecules. Thus, the molecules order themselves quite naturally along their long axes. They can, however, rotate around their axes and slide parallel to one another. In smectic liquid crystals, the intermolecular forces (dispersion forces, dipole–dipole attractions, and hydrogen bonding) limit the ability of the molecules to slide past one another.

▲ Figure 11.33 Molecular structure and liquid crystal temperature range for two typical liquid crystalline materials.

In a **cholesteric liquid crystal**, the molecules are arranged in layers, with their long axes parallel to the other molecules within the same layer.* Upon moving from one layer to the next, the orientation of the molecules rotates by a fixed angle, resulting in a spiral pattern. These liquid crystals are so named because many derivatives of cholesterol adopt this structure.

The molecular arrangement in cholesteric liquid crystals produces unusual coloring patterns with visible light. Changes in temperature and pressure change the order and, hence, the color. Cholesteric liquid crystals are used to monitor temperature changes in situations where conventional methods are not feasible. For example, they can detect hot spots in microelectronic circuits, which may signal the presence of flaws. They can also be fashioned into thermometers for measuring the skin temperature of infants. Because cholesteric liquid crystal displays can be built that draw very little power, they are also being investigated for use in electronic paper (> Figure 11.34). Such applications are possible because an applied electrical field changes the orientation of liquid crystal molecules and thus affects the optical properties of the device.

SAMPLE EXERCISE 11.6 Properties of Liquid Crystals

Which of these substances is most likely to exhibit liquid crystalline behavior?

$$CH_{3}$$

$$CH_{3}-CH_{2}-C-CH_{2}-CH_{3}$$

$$CH_{3}$$

$$CH_{3}$$

$$(i)$$

$$CH_{3}CH_{2}-C-OCH_{3}$$

$$(ii)$$

$$CH_{2}-C-O-Na^{+}$$

$$(iii)$$

SOLUTION

Analyze We have three molecules with different structures, and we are asked to determine which one is most likely to be a liquid crystalline substance.

Plan We need to identify all structural features that might induce liquid crystalline behavior.

Solve Molecule (i) is not likely to be liquid crystalline because the absence of double and/or triple bonds makes this molecule flexible rather than rigid. Molecule (iii) is ionic and the generally high melting points of ionic materials make it unlikely that this substance is liquid crystalline. Molecule (ii) possesses the characteristic long axis and the kinds of structural features often seen in liquid crystals: The molecule has a rod-like shape, the double bonds and benzene rings provide rigidity, and the polar COOCH₃ group creates a dipole moment.

Practice Exercise 1

Liquid crystalline phases are produced by which of the following?
(a) Short, flexible molecules, (b) complete lack of order among molecules, (c) three-dimensional order among molecules, (d) highly branched molecules, (e) rod-shaped molecules.

Practice Exercise 2

▲ Figure 11.34 Electronic paper (e-paper) based on cholesteric liquid crystal technology. Electronic paper mimics the appearance of ordinary ink on paper (like a page of a book or magazine). It has numerous potential uses including thin displays on walls, electronic labels, and electronic book readers.

^{*}Cholesteric liquid crystals are sometimes called chiral nematic phases because the molecules within each plane adopt an arrangement similar to a nematic liquid crystal.

SAMPLE INTEGRATIVE EXERCISE

Putting Concepts Together

The substance CS_2 has a melting point of $-110.8\,^{\circ}C$ and a boiling point of $46.3\,^{\circ}C$. Its density at $20\,^{\circ}C$ is $1.26\,\text{g/cm}^3$. It is highly flammable. (a) What is the name of this compound? (b) List the intermolecular forces that CS_2 molecules exert on one another. (c) Write a balanced equation for the combustion of this compound in air. (You will have to decide on the most likely oxidation products.) (d) The critical temperature and pressure for CS_2 are $552\,\text{K}$ and $78\,\text{atm}$, respectively. Compare these values with those for CO_2 in Table 11.6 and discuss the possible origins of the differences.

SOLUTION

- (a) The compound is named carbon disulfide, in analogy with the naming of other binary molecular compounds such as carbon dioxide. (Section 2.8)
- (b) Because there is no H atom, there can be no hydrogen bonding. If we draw the Lewis structure, we see that carbon forms double bonds with each sulfur:

$$S=C=S$$

Using the VSEPR model ∞ (Section 9.2), we conclude that the molecule is linear and therefore has no dipole moment. ∞ (Section 9.3) Thus, there are no dipole–dipole forces. Only dispersion forces operate between the CS₂ molecules.

(c) The most likely products of the combustion will be CO_2 and SO_2 . ∞ (Section 3.2) Under some conditions SO_3 might be formed, but this would be the less likely outcome. Thus, we have the following equation for combustion:

$$CS_2(l) + 3 O_2(g) \rightarrow CO_2(g) + 2 SO_2(g)$$

(d) The critical temperature and pressure of CS_2 (552 K and 78 atm, respectively) are both higher than those given for CO_2 in Table 11.6 (304 K and 73 atm, respectively). The difference in critical temperatures is especially notable. The higher values for CS_2 arise from the greater dispersion attractions between the CS_2 molecules compared with CO_2 . These greater attractions are due to the larger size of the sulfur compared to oxygen and, therefore, its greater polarizability.

Chapter Summary and Key Terms

A MOLECULAR COMPARISON OF GASES, LIQUIDS, AND SOLIDS (INTRODUCTION AND SECTION 11.1) Substances that are gases or liquids at room temperature are usually composed of molecules. In gases the intermolecular attractive forces are negligible compared to the kinetic energies of the molecules; thus, the molecules are widely separated and undergo constant, chaotic motion. In liquids the intermolecular forces are strong enough to keep the molecules in close proximity; nevertheless, the molecules are free to move with respect to one another. In solids the intermolecular attractive forces are strong enough to restrain molecular motion and to force the particles to occupy specific locations in a three-dimensional arrangement.

INTERMOLECULAR FORCES (SECTION 11.2) Three types of intermolecular forces exist between neutral molecules: **dispersion forces**, **dipole-dipole forces**, and **hydrogen bonding**. Dispersion forces operate between all molecules (and atoms, for atomic substances such as He, Ne, Ar, and so forth). As molecular weight increases, the **polarizability** of a molecule increases, which results in stronger dispersion forces. Molecular shape is also an important factor. Dipole-dipole forces increase in strength as the polarity of the molecule increases. Hydrogen bonding occurs in compounds containing O—H, N—H, and F—H bonds. Hydrogen bonds are generally

stronger than dipole–dipole or dispersion forces. **Ion–dipole forces** are important in solutions in which ionic compounds are dissolved in polar solvents.

SELECT PROPERTIES OF LIQUIDS (SECTION 11.3) The stronger the intermolecular forces, the greater is the **viscosity**, or resistance to flow, of a liquid. The surface tension of a liquid also increases as intermolecular forces increase in strength. **Surface tension** is a measure of the tendency of a liquid to maintain a minimum surface area. The adhesion of a liquid to the walls of a narrow tube and the cohesion of the liquid account for **capillary action**.

PHASE CHANGES (SECTION 11.4) A substance may exist in more than one state of matter, or phase. Phase changes are transformations from one phase to another. Changes of a solid to liquid (melting), solid to gas (sublimation), and liquid to gas (vaporization) are all endothermic processes. Thus, the heat of fusion (melting), the heat of sublimation, and the heat of vaporization are all positive quantities. The reverse processes (freezing, deposition, and condensation) are exothermic.

A gas cannot be liquefied by application of pressure if the temperature is above its **critical temperature**. The pressure required to liquefy a gas at its critical temperature is called the **critical pressure**.

When the temperature exceeds the critical temperature and the pressure exceeds the critical pressure, the liquid and gas phases coalesce to form a **supercritical fluid**.

VAPOR PRESSURE (SECTION 11.5) The **vapor pressure** of a liquid is the partial pressure of the vapor when it is in **dynamic equilibrium** with the liquid. At equilibrium the rate of transfer of molecules from the liquid to the vapor equals the rate of transfer from the vapor to the liquid. The higher the vapor pressure of a liquid, the more readily it evaporates and the more **volatile** it is. Vapor pressure increases with temperature. Boiling occurs when the vapor pressure equals the external pressure. Thus, the **boiling point** of a liquid depends on pressure. The **normal boiling point** is the temperature at which the vapor pressure equals 1 atm.

PHASE DIAGRAMS (SECTION 11.6) The equilibria between the solid, liquid, and gas phases of a substance as a function of temperature and pressure are displayed on a phase diagram. A line indicates equilibria between any two phases. The line through the melting point usually slopes slightly to the right as pressure increases, because the solid is usually more dense than the liquid. The melting point at 1 atm is the normal melting point. The point on the diagram

at which all three phases coexist in equilibrium is called the **triple point**. The **critical point** corresponds to the critical temperature and critical pressure. Beyond the critical point, the substance is a supercritical fluid.

LIQUID CRYSTALS (SECTION 11.7) A liquid crystal is a substance that exhibits one or more ordered phases at a temperature above the melting point of the solid. In a nematic liquid crystal the molecules are aligned along a common direction, but the ends of the molecules are not lined up. In a smectic liquid crystal the ends of the molecules are lined up so that the molecules form layers. In smectic A liquid crystals the long axes of the molecules line up perpendicular to the layers. In smectic C liquid crystals the long axes of molecules are inclined with respect to the layers. A cholesteric liquid crystal is composed of molecules that align parallel to each other within a layer, as they do in nematic liquid crystalline phases, but the direction along which the long axes of the molecules align rotates from one layer to the next to form a helical structure. Substances that form liquid crystals are generally composed of molecules with fairly rigid, elongated shapes, as well as polar groups to help align molecules through dipole-dipole interactions.

Learning Outcomes After studying this chapter, you should be able to:

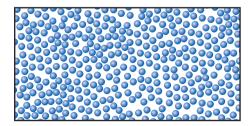

- Identify the intermolecular attractive interactions (dispersion, dipole-dipole, hydrogen bonding, ion-dipole) that exist between molecules or ions based on their composition and molecular structure and compare the relative strengths of these intermolecular forces. (Section 11.2)
- Explain the concept of polarizability and how it relates to dispersion forces. (Section 11.2)
- Explain the concepts of viscosity, surface tension, and capillary action. (Section 11.3)
- List the names of the various changes of state for a pure substance and indicate which are endothermic and which are exothermic. (Section 11.4)

- Interpret heating curves and calculate the enthalpy changes related to temperature changes and phase changes. (Section 11.4)
- Define critical pressure, critical temperature, vapor pressure, normal boiling point, normal melting point, critical point, and triple point. (Sections 11.5 and 11.6)
- Interpret and sketch phase diagrams. Explain how water's phase diagram differs from most other substances and why. (Section 11.6)
- Describe how the molecular arrangements characteristic of nematic, smectic, and cholesteric liquid crystals differ from ordinary liquids and from each other. Recognize the features of molecules that favor formation of liquid crystalline phases. (Section 11.7)

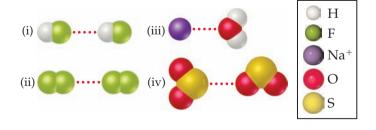

Exercises

Visualizing Concepts

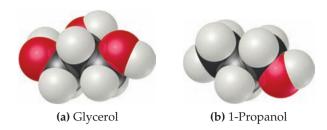

11.1 (a) Does the diagram best describe a crystalline solid, a liquid, or a gas? (b) Explain. [Section 11.1]

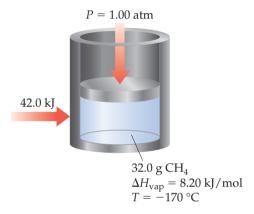

11.2 (a) Which kind of intermolecular attractive force is shown in each case here?

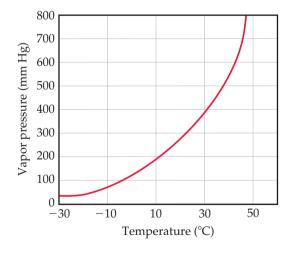

- **(b)** Predict which of the four interactions is the weakest. [Section 11.2]
- 11.3 (a) Do you expect the viscosity of glycerol, $C_3H_5(OH)_3$, to be larger or smaller than that of 1-propanol, C_3H_7OH ? (b) Explain. [Section 11.3]

11.4 If 42.0 kJ of heat is added to a 32.0-g sample of liquid methane under 1 atm of pressure at a temperature of -170 °C, what are the final state and temperature of the methane once the system equilibrates? Assume no heat is lost to the surroundings. The normal boiling point of methane is -161.5 °C. The specific heats of liquid and gaseous methane are 3.48 and 2.22 J/g-K, respectively. [Section 11.4]

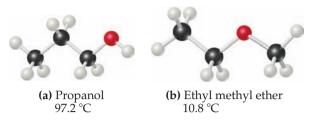

11.5 Using this graph of CS₂ data,

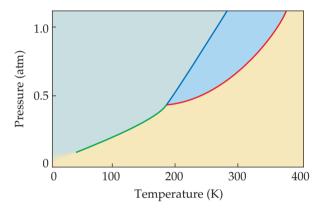

determine (a) the approximate vapor pressure of CS_2 at 30 °C, (b) the temperature at which the vapor pressure equals 300 torr, (c) the normal boiling point of CS_2 . [Section 11.5]

11.6 The molecules

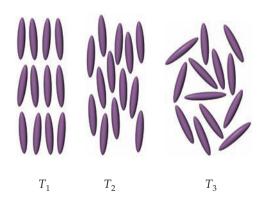

have the same molecular formula (C_3H_8O) but different normal boiling points, as shown. Rationalize the difference in boiling points. [Sections 11.2 and 11.5]

11.7 The phase diagram of a hypothetical substance is

- (a) Estimate the normal boiling point and freezing point of the substance.
- (b) What is the physical state of the substance under the following conditions? (i) T = 150 K, P = 0.2 atm;
 (ii) T = 100 K, P = 0.8 atm; (iii) T = 300 K, P = 1.0 atm.
- (c) What is the triple point of the substance? [Section 11.6]
- **11.8** At three different temperatures, T_1 , T_2 , and T_3 , the molecules in a liquid crystal align in these ways:

- (a) At which temperature or temperatures is the substance in a liquid crystalline state? At those temperatures, which type of liquid crystalline phase is depicted?
- **(b)** Which is the highest of these three temperatures? [Section 11.7]

Molecular Comparisons of Gases, Liquids, and Solids (Section 11.1)

- 11.9 List the three states of matter in order of (a) increasing molecular disorder and (b) increasing intermolecular attraction.
 (c) Which state of matter is most easily compressed?
- 11.10 (a) How does the average kinetic energy of molecules compare with the average energy of attraction between molecules in solids, liquids, and gases? (b) Why does increasing the temperature cause a solid substance to change in succession from a solid to a liquid to a gas? (c) What happens to a gas if you put it under extremely high pressure?
- 11.11 As a metal such as lead melts, what happens to (a) the average kinetic energy of the atoms, (b) the average distance between the atoms?
- **11.12** At room temperature, Si is a solid, CCl₄ is a liquid, and Ar is a gas. List these substances in order of (**a**) increasing intermolecular energy of attraction, (**b**) increasing boiling point.
- 11.13 At standard temperature and pressure the molar volumes of Cl₂ and NH₃ gases are 22.06 and 22.40 L, respectively. (a) Given the different molecular weights, dipole moments, and molecular shapes, why are their molar volumes nearly the same? (b) On cooling to 160 K, both substances form crystalline solids. Do you expect the molar volumes to decrease or increase on cooling the gases to 160 K? (c) The densities of crystalline Cl₂ and NH₃ at 160 K are 2.02 and 0.84 g/cm³, respectively. Calculate their molar volumes. (d) Are the molar volumes in the solid state as similar as they are in the gaseous state? Explain. (e) Would you expect the molar volumes in the liquid state to be closer to those in the solid or gaseous state?
- 11.14 Benzoic acid, C_6H_5COOH , melts at $122\,^{\circ}C$. The density in the liquid state at $130\,^{\circ}C$ is $1.08\,g/cm^3$. The density of solid benzoic acid at $15\,^{\circ}C$ is $1.266\,g/cm^3$. (a) In which of these two states is the average distance between molecules greater? (b) Explain the difference in densities at the two temperatures in terms of the relative kinetic energies of the molecules.

Intermolecular Forces (Section 11.2)

- 11.15 (a) Which type of intermolecular attractive force operates between all molecules? (b) Which type of intermolecular attractive force operates only between polar molecules? (c) Which type of intermolecular attractive force operates only between the hydrogen atom of a polar bond and a nearby small electronegative atom?
- **11.16** (a) Which is generally stronger, intermolecular interactions or intramolecular interactions? (b) Which of these kinds of interactions are broken when a liquid is converted to a gas?
- 11.17 Describe the intermolecular forces that must be overcome to convert these substances from a liquid to a gas: (a) SO₂, (b) CH₃COOH, (c) H₂S.
- 11.18 Which type of intermolecular force accounts for each of these differences? (a) CH₃OH boils at 65 °C; CH₃SH boils at 6 °C. (b) Xe is a liquid at atmospheric pressure and 120 K, whereas Ar is a gas under the same conditions. (c) Kr, atomic weight 84, boils at 120.9 K, whereas Cl₂, molecular weight about 71, boils at 238 K. (d) Acetone boils at 56 °C, whereas 2-methylpropane boils at -12 °C.

$$CH_3$$
 CH_3 CH_3

- 11.19 (a) What is meant by the term *polarizability*? (b) Which of the following atoms would you expect to be most polarizable: N, P, As, Sb? Explain. (c) List the following molecules in order of increasing polarizability: GeCl₄, CH₄, SiCl₄, SiH₄, and GeBr₄. (d) Predict the order of boiling points of the substances in part (c).
- 11.20 True or false:
 - (a) For molecules with similar molecular weights, the dispersion forces become stronger as the molecules become more polarizable.
 - (b) For the noble gases the dispersion forces decrease while the boiling points increase as you go down the column in the periodic table.
 - (c) In terms of the total attractive forces for a given substance, dipole–dipole interactions, when present, are always greater than dispersion forces.
 - (d) All other factors being the same, dispersion forces between linear molecules are greater than those between molecules whose shapes are nearly spherical.
- **11.21** Which member in each pair has the greater dispersion forces? (a) H₂O or H₂S, (b) CO₂ or CO, (c) SiH₄ or GeH₄.
- 11.22 Which member in each pair has the stronger intermolecular dispersion forces? (a) Br₂ or O₂, (b) CH₃CH₂CH₂CH₂SH or CH₃CH₂CH₂CH₂CH₂SH, (c) CH₃CH₂CH₂Cl or (CH₃)₂CHCl.
- 11.23 Butane and 2-methylpropane, whose space-filling models are shown here, are both nonpolar and have the same molecular formula, C_4H_{10} , yet butane has the higher boiling point $(-0.5\,^{\circ}\text{C}\text{ compared to }-11.7\,^{\circ}\text{C})$. Explain.

(a) Butane

(b) 2-Methylpropane

11.24 Propyl alcohol (CH₃CH₂CH₂OH) and isopropyl alcohol [(CH₃)₂CHOH], whose space-filling models are shown, have boiling points of 97.2 and 82.5 °C, respectively. Explain why the boiling point of propyl alcohol is higher, even though both have the molecular formula, C₃H₈O.

(a) Propyl alcohol

(b) Isopropyl alcohol

- 11.25 (a) What atoms must a molecule contain to participate in hydrogen bonding with other molecules of the same kind? (b) Which of the following molecules can form hydrogen bonds with other molecules of the same kind: CH₃F, CH₃NH₂, CH₃OH, CH₃Br?
- 11.26 Rationalize the difference in boiling points in each pair: (a) HF (20 °C) and HCl (-85 °C), (b) CHCl₃ (61 °C) and CHBr₃ (150 °C), (c) Br₂ (59 °C) and ICl (97 °C).
- 11.27 Ethylene glycol (HOCH₂CH₂OH), the major substance in antifreeze, has a normal boiling point of 198 °C. By comparison, ethyl alcohol (CH₃CH₂OH) boils at 78 °C at atmospheric pressure. Ethylene glycol dimethyl ether (CH₃OCH₂CH₂OCH₃) has a normal boiling point of 83 °C, and ethyl methyl ether (CH₃CH₂OCH₃) has a normal boiling point of 11 °C. (a) Explain why replacement of a hydrogen on the oxygen by a CH₃ group generally results in a lower boiling point. (b) What are the major factors responsible for the difference in boiling points of the two ethers?
- 11.28 Based on the type or types of intermolecular forces, predict the substance in each pair that has the higher boiling point:
 (a) propane (C₃H₈) or *n*-butane (C₄H₁₀), (b) diethyl ether (CH₃CH₂OCH₂CH₃) or 1-butanol (CH₃CH₂CH₂CH₂OH),
 (c) sulfur dioxide (SO₂) or sulfur trioxide (SO₃), (d) phosgene (Cl₂CO) or formaldehyde (H₂CO).
- 11.29 Look up and compare the normal boiling points and normal melting points of H₂O and H₂S. Based on these physical properties, which substance has stronger intermolecular forces? What kinds of intermolecular forces exist for each molecule?
- 11.30 The following quote about ammonia (NH₃) is from a text-book of inorganic chemistry: "It is estimated that 26% of the hydrogen bonding in NH₃ breaks down on melting, 7% on warming from the melting to the boiling point, and the final 67% on transfer to the gas phase at the boiling point." From the standpoint of the kinetic energy of the molecules, explain (a) why there is a decrease of hydrogen-bonding energy on melting and (b) why most of the loss in hydrogen bonding occurs in the transition from the liquid to the vapor state.
- 11.31 A number of salts containing the tetrahedral polyatomic anion, BF₄⁻, are ionic liquids, whereas salts containing the somewhat larger tetrahedral ion SO₄²⁻ do not form ionic liquids. Explain this observation.
- **11.32** The generic structural formula for a 1-alkyl-3-methylimid-azolium cation is

$$\begin{bmatrix} H \\ \downarrow \\ C \\ \downarrow \\ C \\ \downarrow \\ C \\ \downarrow \\ C \\ \downarrow \\ H \end{bmatrix}^+$$

where R is a — $CH_2(CH_2)_nCH_3$ alkyl group. The melting points of the salts that form between the 1-alkyl-3-methylimidazolium cation and the PF_6^- anion are as follows: $R = CH_2CH_3$ (m.p. = $60\,^{\circ}$ C), $R = CH_2CH_2CH_3$ (m.p. = $40\,^{\circ}$ C), $R = CH_2CH_2CH_3$ (m.p. = $10\,^{\circ}$ C), and $R = CH_2CH_2CH_2CH_2CH_2CH_3$ (m.p. = $-61\,^{\circ}$ C). Why does the melting point decrease as the length of alkyl group increases?

Select Properties of Liquids (Section 11.3)

- 11.33 (a) What is the relationship between surface tension and temperature? (b) What is the relationship between viscosity and temperature? (c) Why do substances with high surface tension also tend to have high viscosities?
- 11.34 Based on their composition and structure, list CH₂Cl₂, CH₃CH₂CH₃, and CH₃CH₂OH in order of (a) increasing intermolecular forces, (b) increasing viscosity, (c) increasing surface tension.
- 11.35 Explain the following observations: (a) The surface tension of CHBr₃ is greater than that of CHCl₃. (b) As temperature increases, oil flows faster through a narrow tube. (c) Raindrops that collect on a waxed automobile hood take on a nearly spherical shape. (d) Oil droplets that collect on a waxed automobile hood take on a flat shape.
- 11.36 Hydrazine (H₂NNH₂), hydrogen peroxide (HOOH), and water (H₂O) all have exceptionally high surface tensions compared with other substances of comparable molecular weights. (a) Draw the Lewis structures for these three compounds. (b) What structural property do these substances have in common, and how might that account for the high surface tensions?
- **11.37** The boiling points, surface tensions, and viscosities of water and several alcohols are as follows:

	Boiling Point (°C)	Surface Tension (J/m²)	Viscosity (kg/m-s)
Water, H ₂ O	100	7.3×10^{-2}	0.9×10^{-3}
Ethanol, CH ₃ CH ₂ OH	78	2.3×10^{-2}	1.1×10^{-3}
Propanol, CH ₃ CH ₂ CH ₂ OH	97	2.4×10^{-2}	2.2×10^{-3}
<i>n</i> -Butanol, CH ₃ CH ₂ CH ₂ CH ₂ OH	117	2.6×10^{-2}	2.6×10^{-3}
Ethylene glycol, HOCH ₂ CH ₂ OH	197	4.8×10^{-2}	26×10^{-3}

- (a) For ethanol, propanol, and *n*-butanol the boiling points, surface tensions, and viscosities all increase. What is the reason for this increase? (b) How do you explain the fact that propanol and ethylene glycol have similar molecular weights (60 versus 62 amu), yet the viscosity of ethylene glycol is more than 10 times larger than propanol? (c) How do you explain the fact that water has the highest surface tension but the lowest viscosity?
- 11.38 (a) Would you expect the viscosity of *n*-pentane, CH₃CH₂CH₂CH₂CH₃, to be larger or smaller than the viscosity of *n*-hexane, CH₃CH₂CH₂CH₂CH₂CH₃? (b) Would you expect the viscosity of neopentane, (CH₃)₄C, to be smaller or larger than the viscosity of *n*-pentane? (See Figure 11.6 to see the shapes of these molecules.)

Phase Changes (Section 11.4)

11.39 Name the phase transition in each of the following situations and indicate whether it is exothermic or endothermic:(a) When ice is heated, it turns to water. (b) Wet clothes dry on a warm summer day. (c) Frost appears on a window on a cold winter day. (d) Droplets of water appear on a cold glass of beer.

- 11.40 Name the phase transition in each of the following situations and indicate whether it is exothermic or endothermic:
 (a) Bromine vapor turns to bromine liquid as it is cooled.
 (b) Crystals of iodine disappear from an evaporating dish as they stand in a fume hood.
 (c) Rubbing alcohol in an open container slowly disappears.
 (d) Molten lava from a volcano turns into solid rock.
- **11.41** Explain why any substance's heat of fusion is generally lower than its heat of vaporization.
- 11.42 Ethyl chloride (C_2H_5Cl) boils at 12 °C. When liquid C_2H_5Cl under pressure is sprayed on a room-temperature (25 °C) surface in air, the surface is cooled considerably. (a) What does this observation tell us about the specific heat of $C_2H_5Cl(g)$ as compared with that of $C_2H_5Cl(l)$? (b) Assume that the heat lost by the surface is gained by ethyl chloride. What enthalpies must you consider if you were to calculate the final temperature of the surface?
- 11.43 For many years drinking water has been cooled in hot climates by evaporating it from the surfaces of canvas bags or porous clay pots. How many grams of water can be cooled from 35 to 20 °C by the evaporation of 60 g of water? (The heat of vaporization of water in this temperature range is 2.4 kJ/g. The specific heat of water is 4.18 J/g-K.)
- 11.44 Compounds like CCl_2F_2 are known as chlorofluorocarbons, or CFCs. These compounds were once widely used as refrigerants but are now being replaced by compounds that are believed to be less harmful to the environment. The heat of vaporization of CCl_2F_2 is 289 J/g. What mass of this substance must evaporate to freeze 200 g of water initially at 15 °C? (The heat of fusion of water is 334 J/g; the specific heat of water is 4.18 J/g-K.)
- 11.45 Ethanol (C₂H₅OH) melts at -114 °C and boils at 78 °C. The enthalpy of fusion of ethanol is 5.02 kJ/mol, and its enthalpy of vaporization is 38.56 kJ/mol. The specific heats of solid and liquid ethanol are 0.97 and 2.3 J/g-K, respectively.
 (a) How much heat is required to convert 42.0 g of ethanol at 35 °C to the vapor phase at 78 °C? (b) How much heat is required to convert the same amount of ethanol at -155 °C to the vapor phase at 78 °C?
- 11.46 The fluorocarbon compound $C_2Cl_3F_3$ has a normal boiling point of 47.6 °C. The specific heats of $C_2Cl_3F_3(l)$ and $C_2Cl_3F_3(g)$ are 0.91 and 0.67 J/g-K, respectively. The heat of vaporization for the compound is 27.49 kJ/mol. Calculate the heat required to convert 35.0 g of $C_2Cl_3F_3$ from a liquid at 10.00 °C to a gas at 105.00 °C.
- **11.47** (a) What is the significance of the critical pressure of a substance? (b) What happens to the critical temperature of a series of compounds as the force of attraction between molecules increases? (c) Which of the substances listed in Table 11.6 can be liquefied at the temperature of liquid nitrogen (-196 °C)?
- **11.48** The critical temperatures (K) and pressures (atm) of a series of halogenated methanes are as follows:

Compound	CCl ₃ F	CCl ₂ F ₂	CClF ₃	CF ₄
Critical temperature	471	385	302	227
Critical pressure	43.5	40.6	38.2	37.0

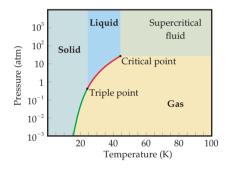

(a) List the intermolecular forces that occur for each compound. (b) Predict the order of increasing intermolecular attraction, from least to most, for this series of compounds. (c) Predict the critical temperature and pressure for CCl₄ based on the trends in this table. Look up the experimentally determined critical temperatures and pressures for CCl₄, using a source such as the CRC Handbook of Chemistry and Physics, and suggest a reason for any discrepancies.

Vapor Pressure (Section 11.5)

- 11.49 Which of the following affects the vapor pressure of a liquid?(a) Volume of the liquid, (b) surface area, (c) intermolecular attractive forces, (d) temperature, (e) density of the liquid.
- 11.50 Acetone (H₃CCOCH₃) has a boiling point of 56 °C. Based on the data given in Figure 11.25, would you expect acetone to have a higher or lower vapor pressure than ethanol at 25 °C?
- 11.51 (a) Place the following substances in order of increasing volatility: CH₄, CBr₄, CH₂Cl₂, CH₃Cl, CHBr₃, and CH₂Br₂. (b) How do the boiling points vary through this series? (c) Explain your answer to part (b) in terms of intermolecular forces.
- 11.52 True or false:
 - (a) CBr₄ is more volatile than CCl₄.
 - (b) CBr₄ has a higher boiling point than CCl₄.
 - (c) CBr₄ has weaker intermolecular forces than CCl₄.
 - (d) CBr₄ has a higher vapor pressure at the same temperature than CCl₄.
- 11.53 (a) Two pans of water are on different burners of a stove. One pan of water is boiling vigorously, while the other is boiling gently. What can be said about the temperature of the water in the two pans? (b) A large container of water and a small one are at the same temperature. What can be said about the relative vapor pressures of the water in the two containers?
- 11.54 Explain the following observations: (a) Water evaporates more quickly on a hot, dry day than on a hot, humid day.(b) It takes longer to cook an egg in boiling water at high altitudes than it does at lower altitudes.
- 11.55 Using the vapor-pressure curves in Figure 11.25, (a) estimate the boiling point of ethanol at an external pressure of 200 torr, (b) estimate the external pressure at which ethanol will boil at 60 °C, (c) estimate the boiling point of diethyl ether at 400 torr, (d) estimate the external pressure at which diethyl ether will boil at 40 °C.
- **11.56** Title of Appendix B lists the vapor pressure of water at various external pressures.
 - (a) Plot the data in Title of Appendix B, vapor pressure (torr) versus temperature (°C). From your plot, estimate the vapor pressure of water at body temperature, 37 °C.
 - (b) Explain the significance of the data point at 760.0 torr, $100\,^{\circ}\text{C}.$
 - (c) A city at an altitude of 5000 ft above sea level has a barometric pressure of 633 torr. To what temperature would you have to heat water to boil it in this city?
 - (d) A city at an altitude of 500 ft below sea level would have a barometric pressure of 774 torr. To what temperature would you have to heat water to boil it in this city?
 - (e) For the two cities in parts (c) and (d), compare the average kinetic energies of the water molecules at their boiling points. Are the kinetic energies the same or different? Explain.

Phase Diagrams (Section 11.6)

- **11.57** (a) What is the significance of the critical point in a phase diagram? (b) Why does the line that separates the gas and liquid phases end at the critical point?
- 11.58 (a) What is the significance of the triple point in a phase diagram? (b) Could you measure the triple point of water by measuring the temperature in a vessel in which water vapor, liquid water, and ice are in equilibrium under 1 atm of air? Explain.
- 11.59 Referring to Figure 11.28, describe all the phase changes that would occur in each of the following cases: (a) Water vapor originally at 0.005 atm and -0.5 °C is slowly compressed at constant temperature until the final pressure is 20 atm. (b) Water originally at 100.0 °C and 0.50 atm is cooled at constant pressure until the temperature is -10 °C.
- 11.60 Referring to Figure 11.29, describe the phase changes (and the temperatures at which they occur) when CO_2 is heated from -80 to -20 °C at (a) a constant pressure of 3 atm, (b) a constant pressure of 6 atm.
- 11.61 The phase diagram for neon is

Use the phase diagram to answer the following questions. (a) What is the approximate value of the normal melting point? (b) Over what pressure range will solid neon sublime? (c) At room temperature $(T = 25 \, ^{\circ}\text{C})$ can neon be liquefied by compressing it?

- 11.62 Use the phase diagram of neon to answer the following questions. (a) What is the approximate value of the normal boiling point? (b) What can you say about the strength of the intermolecular forces in neon and argon based on the critical points of Ne and Ar (see Table 11.6.)?
- 11.63 The fact that water on Earth can readily be found in all three states (solid, liquid, and gas) is in part a consequence of the fact that the triple point of water ($T=0.01\,^{\circ}\text{C}$, $P=0.006\,\text{atm}$) falls within a range of temperatures and pressures found on Earth. Saturn's largest moon Titan has a considerable amount of methane in its atmosphere. The conditions on the surface of Titan are estimated to be $P=1.6\,\text{atm}$ and $T=-178\,^{\circ}\text{C}$. As seen from the phase diagram of methane (Figure 11.30), these conditions are not far from the triple point of methane, raising the tantalizing possibility that solid, liquid, and gaseous methane can be found on Titan. (a) In what state would you expect to find methane on the surface of Titan? (b) On

- moving upward through the atmosphere the pressure will decrease. If we assume that the temperature does not change, what phase change would you expect to see as we move away from the surface?
- 11.64 At 25 °C gallium is a solid with a density of 5.91 g/cm³. Its melting point, 29.8 °C, is low enough that you can melt it by holding it in your hand. The density of liquid gallium just above the melting point is 6.1 g/cm³. Based on this information, what unusual feature would you expect to find in the phase diagram of gallium?

Liquid Crystals (Section 11.7)

- 11.65 In terms of the arrangement and freedom of motion of the molecules, how are the nematic liquid crystalline phase and an ordinary liquid phase similar? How are they different?
- 11.66 What observations made by Reinitzer on cholesteryl benzoate suggested that this substance possesses a liquid crystalline phase?
- 11.67 The molecules shown in Figure 11.33 possess polar groups (that is, groupings of atoms that give rise to sizable dipole moments within the molecules). How might the presence of polar groups enhance the tendency toward liquid crystal formation?
- **11.68** One of the more effective liquid crystalline substances employed in LCDs is the molecule

- (a) How many double bonds are there in this molecule?
- (b) Describe the features of the molecule that make it prone to show liquid crystalline behavior.
- **11.69** For a given substance, the liquid crystalline phase tends to be more viscous than the liquid phase. Why?
- **11.70** Describe how a cholesteric liquid crystal phase differs from a nematic phase.
- 11.71 It often happens that a substance possessing a smectic liquid crystalline phase just above the melting point passes into a nematic liquid crystalline phase at a higher temperature. Account for this type of behavior.
- 11.72 The smectic liquid crystalline phase can be said to be more highly ordered than the nematic phase. In what sense is this true?

Additional Exercises

- 11.73 As the intermolecular attractive forces between molecules increase in magnitude, do you expect each of the following to increase or decrease in magnitude? (a) Vapor pressure, (b) heat of vaporization, (c) boiling point, (d) freezing point, (e) viscosity, (f) surface tension, (g) critical temperature.
- 11.74 The table below lists the density of O_2 at various temperatures and at 1 atm. Graph the data and predict the substance's normal boiling point.

Temperature (K)	Density (mol/L)
60	40.1
70	38.6
80	37.2
90	35.6
100	0.123
120	0.102
140	0.087

- 11.75 Suppose you have two colorless molecular liquids, one boiling at −84 °C, the other at 34 °C, and both at atmospheric pressure. Which of the following statements is correct? For each statement that is not correct, modify the statement so that it is correct. (a) The higher-boiling liquid has greater total intermolecular forces than the lower-boiling liquid. (b) The lower-boiling liquid must consist of nonpolar molecules. (c) The lower-boiling liquid has a lower molecular weight than the higher-boiling liquid. (d) The two liquids have identical vapor pressures at their normal boiling points. (e) At −84 °C both liquids have vapor pressures of 760 mm Hg.
- **11.76** Two isomers of the planar compound 1,2-dichloroethylene are shown here.

- (a) Which of the two isomers will have the stronger dipole–dipole forces? (b) One isomer has a boiling point of 60.3 °C and the other 47.5 °C. Which isomer has which boiling point?
- 11.77 In dichloromethane, $\operatorname{CH_2Cl_2}(\mu=1.60\,\mathrm{D})$, the dispersion force contribution to the intermolecular attractive forces is about five times larger than the dipole–dipole contribution. Compared to $\operatorname{CH_2Cl_2}$, would you expect the relative importance of the dipole–dipole contribution to increase or decrease (a) in dibromomethane ($\mu=1.43\,\mathrm{D}$), (b) in difluoromethane ($\mu=1.93\,\mathrm{D}$)? (c) Explain.
- 11.78 When an atom or a group of atoms is substituted for an H atom in benzene (C_6H_6), the boiling point changes. Explain the order of the following boiling points: C_6H_6 (80 °C), C_6H_5Cl (132 °C), C_6H_5Br (156 °C), C_6H_5OH (182 °C).
- **11.79** The DNA double helix (Figure 24.30) at the atomic level looks like a twisted ladder, where the "rungs" of the ladder consist

of molecules that are hydrogen-bonded together. Sugar and phosphate groups make up the sides of the ladder. Shown are the structures of the adenine-thymine (AT) "base pair" and the guanine-cytosine (GC) base pair:

You can see that AT base pairs are held together by two hydrogen bonds and the GC base pairs are held together by three hydrogen bonds. Which base pair is more stable to heating? Why?

- 11.80 Ethylene glycol ($HOCH_2CH_2OH$) is the major component of antifreeze. It is a slightly viscous liquid, not very volatile at room temperature, with a boiling point of 198 °C. Pentane (C_5H_{12}), which has about the same molecular weight, is a nonviscous liquid that is highly volatile at room temperature and whose boiling point is 36.1 °C. Explain the differences in the physical properties of the two substances.
- 11.81 Use the normal boiling points

propane
$$(C_3H_8)$$
 -42.1 °C
butane (C_4H_{10}) -0.5 °C
pentane (C_5H_{12}) 36.1 °C
hexane (C_6H_{14}) 68.7 °C
heptane (C_7H_{16}) 98.4 °C

to estimate the normal boiling point of octane (C_8H_{18}) . Explain the trend in the boiling points.

- 11.82 One of the attractive features of ionic liquids is their low vapor pressure, which in turn tends to make them non-flammable. Why do you think ionic liquids have lower vapor pressures than most room-temperature molecular liquids?
- 11.83 (a) When you exercise vigorously, you sweat. How does this help your body cool? (b) A flask of water is connected to a vacuum pump. A few moments after the pump is turned on, the water begins to boil. After a few minutes, the water begins to freeze. Explain why these processes occur.

11.84 The following table gives the vapor pressure of hexafluorobenzene (C_6F_6) as a function of temperature:

Temperature (K)	Vapor Pressure (torr)
280.0	32.42
300.0	92.47
320.0	225.1
330.0	334.4
340.0	482.9

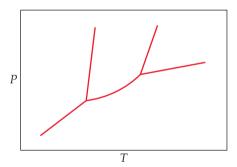

- (a) By plotting these data in a suitable fashion, determine whether the Clausius–Clapeyron equation (Equation 11.1) is obeyed. If it is obeyed, use your plot to determine $\Delta H_{\rm vap}$ for C_6F_6 . (b) Use these data to determine the boiling point of the compound.
- 11.85 Suppose the vapor pressure of a substance is measured at two different temperatures. (a) By using the Clausius–Clapeyron equation (Equation 11.1) derive the following relationship between the vapor pressures, P_1 and P_2 , and the absolute temperatures at which they were measured, T_1 and T_2 :

$$\ln \frac{P_1}{P_2} = -\frac{\Delta H_{\text{vap}}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

- (b) Gasoline is a mixture of hydrocarbons, a major component of which is octane ($CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_3$). Octane has a vapor pressure of 13.95 torr at 25 °C and a vapor pressure of 144.78 torr at 75 °C. Use these data and the equation in part (a) to calculate the heat of vaporization of octane. (c) By using the equation in part (a) and the data given in part (b), calculate the normal boiling point of octane. Compare your answer to the one you obtained from Exercise 11.80. (d) Calculate the vapor pressure of octane at -30 °C.
- 11.86 The following data present the temperatures at which certain vapor pressures are achieved for dichloromethane (CH_2Cl_2) and methyl iodide (CH_3I) :

Vapor Pressure (torr)	10.0	40.0	100.0	400.0
T for CH ₂ Cl ₂ (°C)	-43.3	-22.3	-6.3	24.1
T for CH₃I (°C)	-45.8	-24.2	-7.0	25.3

- (a) Which of the two substances is expected to have the greater dipole–dipole forces? Which is expected to have the greater dispersion forces? Based on your answers, explain why it is difficult to predict which compound would be more volatile. (b) Which compound would you expect to have the higher boiling point? Check your answer in a reference book such as the *CRC Handbook of Chemistry and Physics*. (c) The order of volatility of these two substances changes as the temperature is increased. What quantity must be different for the two substances for this phenomenon to occur? (d) Substantiate your answer for part (c) by drawing an appropriate graph.
- 11.87 Naphalene, ($C_{10}H_8$) is the main ingredient in traditional mothballs. Its normal melting point is 81 °C, its normal boiling point is 218 °C, and its triple point is 80 °C at 1000 Pa. Using the data, construct a phase diagram for naphthalene, labeling all the regions of your diagram.
- 11.88 A watch with a liquid crystal display (LCD) does not function properly when it is exposed to low temperatures during a trip to Antarctica. Explain why the LCD might not function well at low temperature.
- 11.89 A particular liquid crystalline substance has the phase diagram shown in the figure. By analogy with the phase diagram for a non-liquid crystalline substance, identify the phase present in each area.

Integrative Exercises

- 11.90 (a) At the molecular level, what factor is responsible for the steady increase in viscosity with increasing molecular weight in the hydrocarbon series shown in Table 11.5? (b) Although the viscosity varies over a factor of more than two in the series from hexane to nonane, the surface tension at 25 °C increases by only about 20% in the same series. How do you account for this? (c) *n*-octyl alcohol [CH₃(CH₂)₇OH] has a viscosity of 1.01 × 10⁻² kg/m-s, much higher than nonane, which has about the same molecular weight. What accounts for this difference? How does your answer relate to the difference in normal boiling points for these two substances?
- 11.91 Acetone [(CH₃)₂CO] is widely used as an industrial solvent.
 (a) Draw the Lewis structure for the acetone molecule and predict the geometry around each carbon atom. (b) Is the acetone molecule polar or nonpolar? (c) What kinds of intermolecular attractive forces exist between acetone molecules? (d) 1-Propanol (CH₃CH₂CH₂OH) has a molecular weight that is very similar to that of acetone, yet acetone boils at 56.5 °C and 1-propanol boils at 97.2 °C. Explain the difference.
- 11.92 The table shown here lists the molar heats of vaporization for several organic compounds. Use specific examples from this list to illustrate how the heat of vaporization varies with (a) molar mass, (b) molecular shape, (c) molecular polarity, (d) hydrogen-bonding interactions. Explain these comparisons in terms of the nature of the intermolecular forces at work. (You may find it helpful to draw out the structural formula for each compound.)

Compound	Heat of Vaporization (kJ/mol)
CH ₃ CH ₂ CH ₃	19.0
CH ₃ CH ₂ CH ₂ CH ₂ CH ₃	27.6
CH ₃ CHBrCH ₃	31.8
CH ₃ COCH ₃	32.0
CH ₃ CH ₂ CH ₂ Br	33.6
CH ₃ CH ₂ CH ₂ OH	47.3

- 11.93 The vapor pressure of ethanol (C_2H_5OH) at 19 °C is 40.0 torr. A 1.00-g sample of ethanol is placed in a 2.00 L container at 19 °C. If the container is closed and the ethanol is allowed to reach equilibrium with its vapor, how many grams of liquid ethanol remain?
- 11.94 Liquid butane (C_4H_{10}) is stored in cylinders to be used as a fuel. The normal boiling point of butane is listed as $-0.5\,^{\circ}$ C. (a) Suppose the tank is standing in the Sun and reaches a temperature of 35 $^{\circ}$ C. Would you expect the pressure in the tank to be greater or less than atmospheric pressure? How does the pressure within the tank depend on how much liquid butane is in it? (b) Suppose the valve to the tank is opened and a few liters of butane are allowed to escape rapidly. What do you expect would happen to the temperature of the remaining liquid butane in the tank? Explain. (c) How much heat must be added to vaporize 250 g of butane if its heat of vaporization is $21.3\,\mathrm{kJ/mol}$? What volume does this much butane occupy at 755 torr and 35 $^{\circ}$ C?
- 11.95 Using information in Titles of Appendices B and C, calculate the minimum grams of propane, $C_3H_8(g)$, that must be combusted to provide the energy necessary to convert 5.50 kg of ice at $-20\,^{\circ}\text{C}$ to liquid water at 75 $^{\circ}\text{C}$.
- 11.96 The vapor pressure of a volatile liquid can be determined by slowly bubbling a known volume of gas through it at a known temperature and pressure. In an experiment, $5.00 \, \text{L}$ of N_2 gas is passed through $7.2146 \, \text{g}$ of liquid benzene (C_6H_6) at $26.0 \, ^{\circ}\text{C}$. The liquid remaining after the experiment weighs $5.1493 \, \text{g}$. Assuming that the gas becomes saturated with benzene vapor and that the total gas volume and temperature remain constant, what is the vapor pressure of the benzene in torr?
- 11.97 The relative humidity of air equals the ratio of the partial pressure of water in the air to the equilibrium vapor pressure of water at the same temperature times 100%. If the relative humidity of the air is 58% and its temperature is 68 °F, how many molecules of water are present in a room measuring $12 \text{ ft} \times 10 \text{ ft} \times 8 \text{ ft}$?

Design an Experiment

Hydraulic fluids are used to transfer power in hydraulic machinery such as aircraft flight controls, excavating equipment, and hydraulic brakes. The power is transferred by the fluid, which is distributed through hoses and tubes by means of various pumps and valves. Imagine that an organic liquid is needed to serve as a hydraulic fluid over a range of temperatures. The three isomers of hexanol are hypothesized to be potentially suitable. These compounds all have a six-carbon backbone with —OH groups on the first, second, or third carbon of the chain. (See Section 2.9 for nomenclature of simple organic substances.) These three substances will have similar yet differing key properties. (a) What properties would be important in this application? (b) Once you have identified at least two properties required for the application, describe the experiments you would carry out to determine which of the three alcohols would be best suited for use as a hydraulic fluid. (c) The class of compounds called *hexanediols* is related to hexanols except that they have two —OH groups attached to the six-carbon backbone. Hypothesize how the key properties you discuss here would change from a hexanol to a hexanediol. Could your experimental procedures be used to explore these properties for hexanediols?

Solids and Modern Materials

Modern devices like computers and cell phones are built from solids with very specific physical properties. For example, the integrated circuit that is at the heart of many electronic devices is built from semiconductors like silicon, metals like copper, and insulators like hafnium oxide.

Scientists and engineers turn almost exclusively to solids for materials used in many other technologies: *alloys* for magnets and airplane turbines, *semiconductors* for solar cells and light-emitting diodes, and *polymers* for packaging and biomedical applications. Chemists have contributed to the discovery and development of new materials either by inventing new substances or by developing the means to process natural materials to form substances that have specific electrical, magnetic, optical, or mechanical properties. In this chapter, we explore the structures and properties of solids. As we do so, we will examine some of the solid materials used in modern technology.

12.1 | Classification of Solids

Solids can be as hard as diamond or as soft as wax. Some readily conduct electricity, whereas others do not. The shapes of some solids can easily be manipulated, while others are brittle and resistant to any change in shape. The physical properties as well as

THE TOUCH SCREEN OF A SMART

PHONE contains materials that are electrically connected to a power source and emit light. Each pixel shown here contains light-emitting diodes (LEDs), which are made of materials that produce specific colors of light in response to an applied voltage. Each pixel must switch on or off in less than a millisecond in response to touch. Devices such as this would not be possible without advanced solid-state and polymer materials.

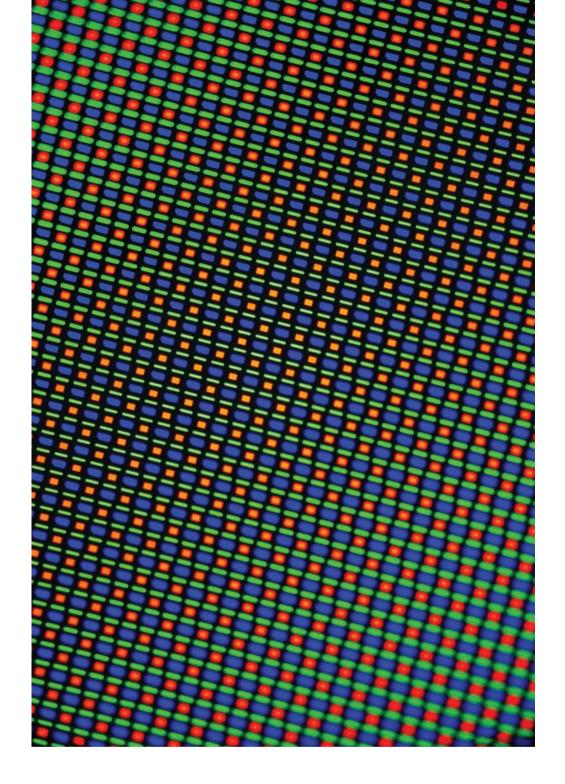

12.1 CLASSIFICATION OF SOLIDS We see that solids can be classified according to the types of bonding interactions that hold the atoms together. This classification helps us make general predictions about the properties of solids.

12.2 STRUCTURES OF SOLIDS We learn that in *crystalline* solids the atoms are arranged in an orderly, repeating pattern but in *amorphous solids* this order is missing. We learn about *lattices* and *unit cells*, which define the repeating patterns that characterize crystalline solids.

12.3 METALLIC SOLIDS We examine the properties and structures of metals. We learn that many metals have structures in which the atoms pack together as closely as possible. We examine various types of *alloys*, materials that contain more than one element and display the characteristic properties of a metal.

12.4 METALLIC BONDING We take a closer look at metallic bonding and how it is responsible for the properties of metals, in terms of two models—the *electron-sea model* and the molecular–orbital model. We learn how overlap of atomic orbitals gives rise to *bands* in metals.

12.5 IONIC SOLIDS We examine the structures and properties of solids held together by the mutual attractions between cations and anions. We learn how the structures of ionic solids depend on the relative sizes of the ions and their stoichiometry.

12.6 MOLECULAR SOLIDS We take a brief look at the solids that form when molecules are held together by weak intermolecular forces.

12.7 COVALENT-NETWORK SOLIDS We learn about solids in which the atoms are held together by extended networks of covalent bonds. We learn how the electronic structure and properties of *semiconductors* differ from those of metals.

12.8 POLYMERS We investigate *polymers*—long chain-like molecules in which the motif of a small molecule is repeated many times over. We see how both molecular shape and interactions between polymer chains affect the physical properties of polymers.

12.9 NANOMATERIALS We learn how the physical and chemical properties of materials change when their crystals become very small. These effects begin to occur when materials have sizes on the order of 1–100 nm. We explore lower-dimensional forms of carbon—fullerenes, carbon nanotubes, and graphene.

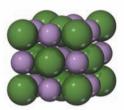

the structures of solids are dictated by the types of bonds that hold the atoms in place. We can classify solids according to those bonds (▼ Figure 12.1).

Metallic solids are held together by a delocalized "sea" of collectively shared valence electrons. This form of bonding allows metals to conduct electricity. It is also responsible for the fact that most metals are relatively strong without being brittle. Ionic solids are held together by the mutual electrostatic attraction between cations and anions. Differences between ionic and metallic bonding make the electrical and mechanical properties of ionic solids very different from those of metals: Ionic solids do not conduct electricity well and are brittle. Covalent-network solids are held together by an extended network of covalent bonds. This type of bonding can result in materials that are extremely hard, like diamond, and it is also responsible for the unique properties of semiconductors. Molecular solids are held together by the intermolecular forces we studied in Chapter 11: dispersion forces, dipole—dipole interactions, and hydrogen bonds. Because these forces are relatively weak, molecular solids tend to be soft and have low melting points.

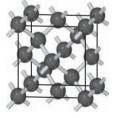

Metallic solids

Extended networks of atoms held together by metallic bonding (Cu, Fe)

Ionic solids

Extended networks of ions held together by ion–ion interactions (NaCl, MgO)

Covalent-network solids

Extended networks of atoms held together by covalent bonds (C, Si)

Molecular solids

Discrete molecules held together by intermolecular forces (HBr, H₂O)

▲ Figure 12.1 Classification and examples of solids according to predominant bonding type.

We will also consider two classes of solids that do not fall neatly into the preceding categories: polymers and nanomaterials. **Polymers** contain long chains of atoms (usually carbon), where the atoms within a given chain are connected by covalent bonds and adjacent chains are held to one another largely by weaker intermolecular forces. Polymers are normally stronger and have higher melting points than molecular solids, and they are more flexible than metallic, ionic, or covalent-network solids. **Nanomaterials** are solids in which the dimensions of individual crystals have been reduced to the order of 1–100 nm. As we will see, the properties of conventional materials change when their crystals become this small.

12.2 | Structures of Solids

Crystalline and Amorphous Solids

Solids contain large numbers of atoms. For example, a 1-carat diamond has a volume of 57 mm³ and contains 1.0×10^{22} carbon atoms. How can we hope to describe such a large collection of atoms? Fortunately, the structures of many solids have patterns that

repeat over and over in three dimensions. We can visualize the solid as being formed by stacking a large number of small, identical structural units, much like a wall can be built by stacking identical bricks.

Solids in which atoms are arranged in an orderly repeating pattern are called **crystalline solids**. These solids usually have flat surfaces, or *faces*, that make definite angles with one another. The orderly arrangements of atoms that produce these faces also cause the solids to have highly regular shapes (**Figure 12.2**). Examples of crystalline solids include sodium chloride, quartz, and diamond.

Amorphous solids (from the Greek words for "without form") lack the order found in crystalline solids. At the atomic level the structures of amorphous solids are similar to the structures of liquids, but the molecules, atoms, and/or ions lack the freedom of motion they have in liquids. Amorphous solids do not have the well-defined faces and shapes of a crystal. Familiar amorphous solids are rubber, glass, and obsidian (volcanic glass).

Unit Cells and Crystal Lattices

In a crystalline solid there is a relatively small repeating unit, called a **unit cell**, that is made up of a unique arrangement of atoms and embodies the structure of the solid. The structure of the crystal can be built by stacking this unit over and over in all three dimensions. Thus, the structure of a crystalline solid is defined by (a) the size and shape of the unit cell and (b) the locations of atoms within the unit cell.

The geometrical pattern of points on which the unit cells are arranged is called a **crystal lattice**. The crystal lattice is, in effect, an abstract (that is, not real) scaffolding for the crystal structure. We can imagine forming the entire crystal structure by first building the scaffolding and then filling in each unit cell with the same atom or group of atoms.

Before describing the structures of solids, we need to understand the properties of crystal lattices. It is useful to begin with two-dimensional lattices because they are simpler to visualize than three-dimensional ones. \triangleright Figure 12.3 shows a two-dimensional array of lattice points. Each lattice point has an identical environment. The positions of the lattice points are defined by the lattice vectors a and b. Beginning from any lattice point it is possible to move to any other lattice point by adding together whole-number multiples of the two lattice vectors.*

The parallelogram formed by the lattice vectors, the shaded region in Figure 12.3, defines the unit cell. In two dimensions the unit cells must *tile*, or fit together in space, in such a way that they completely cover the area of the lattice with no gaps. In three dimensions the unit cells must stack together to fill all space.

In a two-dimensional lattice, the unit cells can take only one of the five shapes shown in Figure 12.4. The most general type of lattice is the *oblique lattice*. In this lattice, the lattice vectors are of different lengths and the angle γ between them is of arbitrary size, which makes the unit cell an arbitrarily shaped parallelogram. A *square lattice* results when the lattice vectors are equal in length and the angle between them is 90°. A *rectangular lattice* is formed when the angle between the lattice vectors is 90° but the vectors have different lengths. The fourth type of two-dimensional lattice, where a and b are of the same length and γ is 120°, is a *hexagonal lattice*. If a and b are of the same length but the angle between them is any value other than 90° or 120° a *rhombic lattice* results. For a rhombic lattice an alternative unit cell can be drawn, a rectangle with lattice points on its corners *and* its center (shown in green in Figure 12.4). Because of this the rhombic lattice is commonly referred to as a *centered rectangular lattice*. The lattices in Figure 12.4 represent five basic shapes: squares, rectangles, hexagons, rhombuses (diamonds), and arbitrary parallelograms. Other polygons, such as pentagons, cannot cover space without leaving gaps, as Figure 12.5 shows.

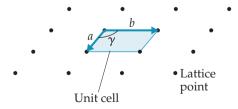

Iron pyrite (Fe S_2), a crystaline solid

Obsidian (typically KAlSi₃O₈), an amorphous solid

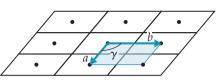

▲ Figure 12.2 Examples of crystalline and amorphous solids. The atoms in crystalline solids repeat in an orderly, periodic fashion that leads to well-defined faces at the macroscopic level. This order is lacking in amorphous solids like obsidian (volcanic glass).

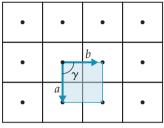

▲ Figure 12.3 A crystalline lattice in two dimensions. An infinite array of lattice points is generated by adding together the lattice vectors *a* and *b*. The unit cell is a parallelogram defined by the lattice vectors.

^{*}A vector is a quantity involving both a direction and a magnitude. The magnitudes of the vectors in Figure 12.3 are indicated by their lengths, and their directions are indicated by the arrowheads.

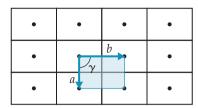

[†]You may wonder why the hexagonal unit cell is not shaped like a hexagon. Remember that the unit cell is by definition a *parallelogram* whose size and shape are defined by the lattice vectors a and b.

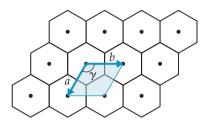

Oblique lattice ($a \neq b$, $\gamma = arbitrary$)

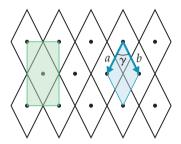

Square lattice (a = b, $\gamma = 90^{\circ}$)

Rectangular lattice ($a \neq b$, $\gamma = 90^{\circ}$)

Hexagonal lattice (a = b, $\gamma = 120^{\circ}$)

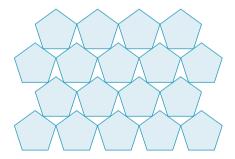

Rhombic lattice (a = b, $\gamma = arbitrary$) Centered rectangular lattice

▲ Figure 12.4 The five two-dimensional lattices. The primitive unit cell for each lattice is shaded in blue. For the rhombic lattice the centered rectangular unit cell is shaded in green. Unlike the primitive rhombic unit cell, the centered cell has two lattice points per unit cell.

GO FIGURE

Why is there a centered rectangular lattice but not a centered square lattice?

▲ Figure 12.5 Not all shapes tile space. Tiling means covering a surface entirely, which is impossible for some geometric shapes, as shown here for pentagons.

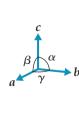

To understand real crystals, we must consider three dimensions. A three-dimensional lattice is defined by *three* lattice vectors a, b, and c (\triangledown Figure 12.6). These lattice vectors define a unit cell that is a parallelepiped (a six-sided figure whose faces are all parallelograms) and is described by the lengths a, b, c of the cell edges and the angles α , β , γ between these edges. There are seven possible shapes for a three-dimensional unit cell, as shown in Figure 12.6.

Give It Some Thought

Imagine you generate a three-dimensional lattice by taking a and b vectors that form a two-dimensional square lattice. Then add a third vector, c, that is of different length and perpendicular to the first two. Which of the seven threedimensional lattices results?

If we place a lattice point at each corner of a unit cell, we get a **primitive lattice**. All seven lattices in Figure 12.6 are primitive lattices. It is also possible to generate

Cubic a = b = c $\alpha = \beta = \gamma = 90^{\circ}$

Orthorhombic $a \neq b \neq c$ $\alpha = \beta = \gamma = 90^{\circ}$

Rhombohedral a = b = c $\alpha = \beta = \gamma \neq 90^{\circ}$

Hexagonal $a = b \neq c$ $\alpha = \beta = 90^{\circ}, \gamma = 120^{\circ}$

Monoclinic $a \neq b \neq c$ $\alpha = \gamma = 90^{\circ}, \beta \neq 90^{\circ}$

Triclinic $a \neq b \neq c$ $\alpha \neq \beta \neq \gamma$

▲ Figure 12.6 The seven three-dimensional primitive lattices.

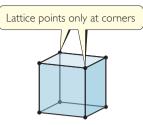

what are called *centered lattices* by placing additional lattice points in specific locations in the unit cell. This is illustrated for a cubic lattice in ▶ Figure 12.7. A body-centered cubic lattice has one lattice point at the center of the unit cell in addition to the lattice points at the eight corners. A face-centered cubic lattice has one lattice point at the center of each of the six faces of the unit cell in addition to the lattice points at the eight corners. Centered lattices exist for other types of unit cells as well. For the crystals discussed in this chapter we need consider only the lattices shown in Figures 12.6 and 12.7.

Filling the Unit Cell

The lattice by itself does not define a crystal structure. To generate a crystal structure, we need to associate an atom or group of atoms with each lattice point. In the simplest case, the crystal structure consists of identical atoms, and each atom lies directly on a lattice point. When this happens, the crystal structure and the lattice points have identical patterns. Many metallic elements adopt such structures, as we will see in Section 12.3. Only for solids in which all the atoms are identical can this occur; in other words, *only elements* can form structures of this type. For compounds, even if we were to put an atom on every lattice point, the points would not be identical because the atoms are not all the same.

In most crystals, the atoms are not exactly coincident with the lattice points. Instead, a group of atoms, called a **motif**, is associated with each lattice point. The unit cell contains a specific motif of atoms, and the crystal structure is built up by repeating the unit cell over and over. This process is illustrated in ▼ Figure 12.8 for a two-dimensional crystal based on a hexagonal unit cell and a two-carbon-atom motif. The resulting infinite two-dimensional honeycomb structure is a two-dimensional crystal called *graphene*, a material that has so many interesting properties that its modern discoverers won the Nobel Prize in Physics in 2010. Each carbon atom is covalently bonded to three neighboring carbon atoms in what amounts to an infinite sheet of interconnected hexagonal rings.

The crystal structure of graphene illustrates two important characteristics of crystals. First, we see that no atoms lie on the lattice points. While most of the structures we discuss in this chapter do have atoms on the lattice points, there are many examples, like graphene, where this is not the case. Thus, to build up a structure you must know the location and orientation of the atoms in the motif with respect to the lattice points. Second, we see that bonds can be formed between atoms in neighboring unit cells and the bonds between atoms need not be parallel to the lattice vectors.

A Closer Look

X-ray Diffraction

When light waves pass through a narrow slit, they are scattered in such a way that the wave seems to spread out. This physical phenomenon is called *diffraction*. When light passes through many evenly spaced narrow slits (a *diffraction grating*), the scattered waves interact to form a series of bright and dark bands, known as a diffraction pattern. The bright bands correspond to constructive overlapping of the light waves, and the dark bands correspond to destructive overlapping of the light waves. (Section 9.8, "Phases in Atomic and Molecular Orbitals") The most effective diffraction of light occurs when the wavelength of the light and the width of the slits are similar in magnitude.

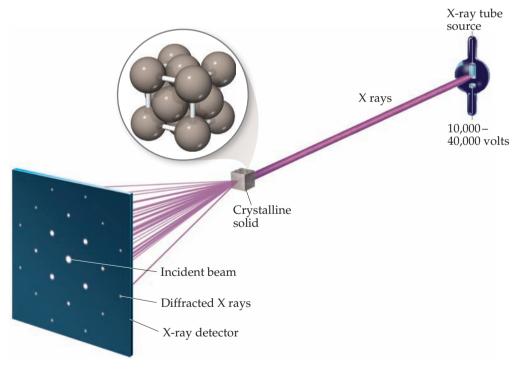

The spacing of the layers of atoms in solid crystals is usually about 2–20 Å. The wavelengths of X rays are also in this range. Thus, a crystal can serve as an effective diffraction grating for X rays. X-ray diffraction results from the scattering of X rays by a regular arrangement of atoms, molecules, or ions. Much of what we know about crystal structures has been obtained by looking at the diffraction patterns that result when X rays pass through a crystal, a technique known as X-ray crystallography. As shown in ∇ Figure 12.9 a monochromatic beam of X rays is passed through a crystal. The diffraction pattern that results is recorded. For many years the diffracted X rays were detected

by photographic film. Today, crystallographers use an *array detector*, a device analogous to that used in digital cameras, to capture and measure the intensities of the diffracted rays.

The pattern of spots on the detector in Figure 12.9 depends on the particular arrangement of atoms in the crystal. The spacing and symmetry of the bright spots, where constructive interference occurs, provide information about the size and shape of the unit cell. The intensities of the spots provide information that can be used to determine the locations of the atoms within the unit cell. When combined, these two pieces of information give the atomic structure that defines the crystal.

X-ray crystallography is used extensively to determine the structures of molecules in crystals. The instruments used to measure X-ray diffraction, known as *X-ray diffractometers*, are now computer controlled, making the collection of diffraction data highly automated. The diffraction pattern of a crystal can be determined very accurately and quickly (sometimes in a matter of hours), even though thousands of diffraction spots are measured. Computer programs are then used to analyze the diffraction data and determine the arrangement and structure of the molecules in the crystal. X-ray diffraction is an important technique in industries ranging from steel and cement manufacture to pharmaceuticals.

▲ Figure 12.9 Diffraction of X rays by a crystal. A monochromatic X-ray beam is passed through a crystal. The X rays are diffracted, and the resulting interference pattern is recorded. The crystal is rotated and another diffraction pattern recorded. Analysis of many diffraction patterns gives the positions of the atoms in the crystal.

12.3 | Metallic Solids

Metallic solids, also simply called *metals*, consist entirely of metal atoms. The bonding in metals is too strong to be due to dispersion forces, and yet there are not enough valence electrons to form covalent bonds between atoms. The bonding, called *metallic*

bonding, happens because the valence electrons are *delocalized* throughout the entire solid. That is, the valence electrons are not associated with specific atoms or bonds but are spread throughout the solid. In fact, we can visualize a metal as an array of positive ions immersed in a "sea" of delocalized valence electrons.

You have probably held a length of copper wire or an iron bolt. Perhaps you have even seen the surface of a freshly cut piece of sodium metal. These substances, although distinct from one another, share certain similarities that enable us to classify them as metallic. A clean metal surface has a characteristic luster. Metals have a characteristic cold feeling when you touch them, related to their high thermal conductivity (ability to conduct heat). Metals also have high electrical conductivity, which means that electrically charged particles flow easily through them. The thermal conductivity of a metal usually parallels its electrical conductivity. Silver and copper, for example, which possess the highest electrical conductivities among the elements, also possess the highest thermal conductivities.

Most metals are *malleable*, which means that they can be hammered into thin sheets, and *ductile*, which means that they can be drawn into wires (▶ Figure 12.10). These properties indicate that the atoms are capable of slipping past one another. Ionic and covalent-network solids do not exhibit such behavior; they are typically brittle.

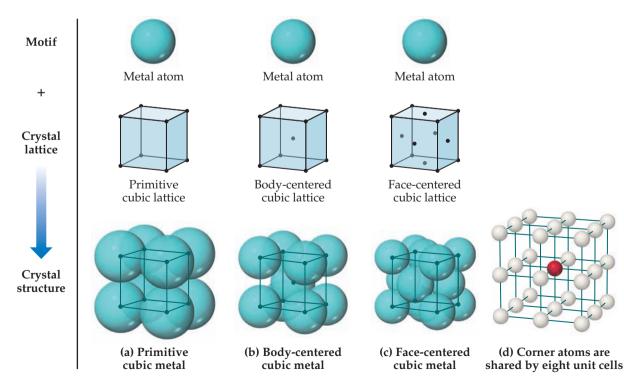

Give It Some Thought

Atoms in metals easily slip past one another as mechanical force is applied; can you think of why this would not be true for ionic solids?

The Structures of Metallic Solids

The crystal structures of many metals are simple enough that we can generate the structure by placing a single atom on each lattice point. The structures corresponding to the three cubic lattices are shown in ▼ Figure 12.11. Metals with a primitive cubic structure are rare, one of the few examples being the radioactive element polonium. Body-centered cubic metals include iron, chromium, sodium, and tungsten. Examples of face-centered cubic metals include aluminum, lead, copper, silver, and gold.

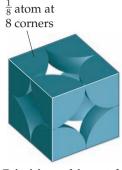

▲ Figure 12.11 The structures of (a) primitive cubic, (b) body-centered cubic, and (c) face-centered cubic metals. Each structure can be generated by the combination of a single-atom motif and the appropriate lattice. (d) Corner atoms (one shown in red) are shared among eight neighboring cubic unit cells.

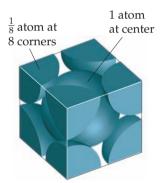

▲ Figure 12.10 Malleability and ductility. Gold leaf demonstrates the characteristic malleability of metals, and copper wire demonstrates their ductility.

GO FIGURE

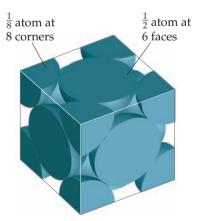

Which one of these unit cells would you expect to represent the densest packing of spheres?

(a) Primitive cubic metal 1 atom per unit cell

(b) Body-centered cubic metal 2 atoms per unit cell

(c) Face-centered cubic metal 4 atoms per unit cell

▲ Figure 12.12 A space-filling view of unit cells for metals with a cubic structure. Only the portion of each atom that falls within the unit cell is shown.

Notice in the bottom row of Figure 12.11 that the atoms on the corners and faces of a unit cell do not lie wholly within the unit cell. These corner and face atoms are shared by neighboring unit cells. An atom that sits at the corner of a unit cell is shared among eight unit cells, and only 1/8 of the atom is in one particular unit cell. Because a cube has eight corners, each primitive cubic unit cell contains $(1/8) \times 8 = 1$ atom, as shown in \P Figure 12.12(a). Similarly, each body-centered cubic unit cell [Figure 12.12(b)] contains two atoms, $(1/8) \times 8 = 1$ from the corners and 1 at the center of the unit cell. Atoms that lie on the face of a unit cell, as they do in a face-centered cubic metal, are shared by two unit cells so that only one-half of the atom belongs to each unit cell. Therefore, a face-centered cubic unit cell [Figure 12.12(c)] contains four atoms, $(1/8) \times 8 = 1$ atom from the corners and $(1/2) \times 6 = 3$ atoms from the faces.

▼ Table 12.1 summarizes how the fractional part of each atom that resides within a unit cell depends on the atom's location within the cell.

Close Packing

The shortage of valence electrons and the fact that they are collectively shared make it favorable for the atoms in a metal to pack together closely. Because we can treat atoms as spherical objects, we can understand the structures of metals by considering how spheres pack. The most efficient way to pack one layer of equal-sized spheres is to surround each sphere by six neighbors, as shown at the top of Figure 12.13. To form a three-dimensional structure, we need to stack additional layers on top of this base layer. To maximize packing efficiency the second layer of spheres must sit in the depressions formed by the spheres in the first layer. We can either put the next layer of atoms into the depressions marked by the yellow dot or the depressions marked by the red dot (realizing that the spheres are too large to simultaneously fill both sets of depressions). For the sake of discussion we arbitrarily put the second layer in the yellow depressions.

For the third layer, we have two choices for where to place the spheres. One possibility is to put the third layer in the depressions that lie directly over the spheres in the first layer. This is done on the left-hand side of Figure 12.13, as shown by the dashed red lines in the side view. Continuing with this pattern, the fourth layer would lie directly over the spheres in the second layer, leading to the ABAB stacking pattern seen on the left, which is called **hexagonal close packing** (hcp). Alternatively, the thirdlayer spheres could lie directly over the depressions that were marked with red dots in the first layer. In this arrangement the spheres in the third layer do not sit directly above the spheres in either of the first two layers, as shown by the dashed red lines on the lower right-hand side of Figure 12.13. If this sequence is repeated in subsequent layers, we derive an ABCABC stacking pattern shown on the right known as cubic close packing (ccp). In both hexagonal close packing and cubic close packing, each sphere has 12 equidistant nearest neighbors: six neighbors in the same layer, three from the layer above, and three from the layer below. We say that each sphere has a coordination number of 12. The coordination number is the number of atoms immediately surrounding a given atom in a crystal structure.

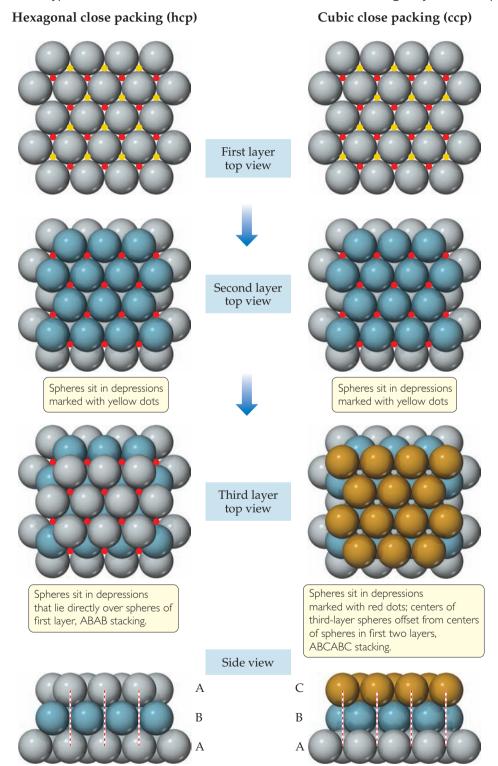

Table 12.1 Fraction of Any Atom as a Function of Location Within the Unit Cell*

Atom Location	Number of Unit Cells Sharing Atom	Fraction of Atom Within Unit Cell
Corner	8	1/8 or 12.5%
Edge	4	1/4 or 25%
Face	2	1/2 or 50%
Anywhere else	1	1 or 100%

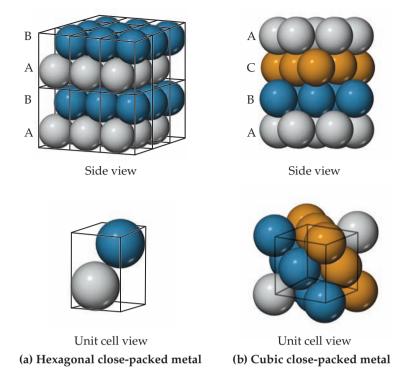

^{*}It is only the position of the center of the atom that matters. Atoms that reside near the boundary of the unit cell but not on a corner, edge, or face are counted as residing 100% within the unit cell.

GO FIGURE

What type of two-dimensional lattice describes the structure of a single layer of close-packed atoms?

▲ Figure 12.13 Close packing of equal-sized spheres. Hexagonal (left) close packing and cubic (right) close packing are equally efficient ways of packing spheres. The red and yellow dots indicate the positions of depressions between atoms.

▲ Figure 12.14 The unit cells for (a) a hexagonal close-packed metal and (b) a cubic close-packed metal. The solid lines indicate the unit cell boundaries. Colors are used to distinguish one layer of atoms from another.

The extended structure of a hexagonal close-packed metal is shown in ▲ Figure 12.14(a). There are two atoms in the primitive hexagonal unit cell, one from each layer. Neither atom sits directly on the lattice points, which are located at the corners of the unit cell. The presence of two atoms in the unit cell is consistent with the two-layer ABAB stacking sequence associated with hcp packing.

Although it is not immediately obvious, the structure that results from cubic close packing possesses a unit cell that is identical to the face-centered cubic unit cell we encountered earlier [Figure $12.11(\mathbf{c})$]. The relationship between the ABC layer stacking and the face-centered cubic unit cell is shown in Figure $12.14(\mathbf{b})$. In this figure we see that the layers stack perpendicular to the body diagonal of the cubic unit cell.

SAMPLE EXERCISE 12.1 Calculating Packing Efficiency

It is not possible to pack spheres together without leaving some void spaces between the spheres. *Packing efficiency* is the fraction of space in a crystal that is actually occupied by atoms. Determine the packing efficiency of a face-centered cubic metal.

SOLUTION

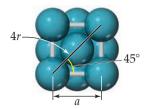

Analyze We must determine the volume taken up by the atoms that reside in the unit cell and divide this number by the volume of the unit cell.

Plan We can calculate the volume taken up by atoms by multiplying the number of atoms per unit cell by the volume of a sphere, $4\pi r^3/3$. To determine the volume of the unit cell, we must first identify the direction along which the atoms touch each other. We can then use geometry to express the length of the cubic unit cell edge, a, in terms of the radius of the atoms. Once we know the edge length, the cell volume is simply a^3 .

Solve As shown in Figure 12.12, a face-centered cubic metal has four atoms per unit cell. Therefore, the volume occupied by the atoms is

Occupied volume =
$$4 \times \left(\frac{4\pi r^3}{3}\right) = \frac{16\pi r^3}{3}$$

For a face-centered cubic metal the atoms touch along the diagonal of a face of the unit cell:

Therefore, a diagonal across a face of the unit cell is equal to four times the atomic radius, r. Using simple trigonometry, and the identity $\cos(45^\circ) = \sqrt{2}/2$, we can show that

$$a = 4r \cos(45^{\circ}) = 4r(\sqrt{2}/2) = (2\sqrt{2})r$$

Finally, we calculate the packing efficiency by dividing the volume occupied by atoms by the volume of the cubic unit cell, a^3 :

Packing efficiency =
$$\frac{\text{volume of atoms}}{\text{volume of unit cell}} = \frac{\left(\frac{16}{3}\right)\pi r^3}{(2\sqrt{2})^3 r^3} = 0.74 \text{ or } 74\%$$

Practice Exercise 1

Consider the two-dimensional square lattice of Figure 12.4. The "packing efficiency" for a two-dimensional structure would be the area of the atoms divided by the area of the unit cell, times 100%. What is the packing efficiency for a square lattice for atoms of radius *a*/2 that are centered at the lattice points? (a) 3.14% (b) 15.7% (c) 31.8% (d) 74.0% (e) 78.5%

Practice Exercise 2

Determine the packing efficiency by calculating the fraction of space occupied by atoms in a body-centered cubic metal.

Give It Some Thought

For metallic structures, does the packing efficiency (see Sample Exercise 12.1) increase or decrease as the number of nearest neighbors (the coordination number) decreases?

Alloys

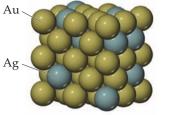

An **alloy** is a material that contains more than one element and has the characteristic properties of a metal. The alloying of metals is of great importance because it is one of the primary ways of modifying the properties of pure metallic elements. Nearly all the common uses of iron, for example, involve alloy compositions (for example, stainless steel). Bronze is formed by alloying copper and tin, while brass is an alloy of copper and zinc. Pure gold is too soft to be used in jewelry, but alloys of gold are much harder (see "Chemistry Put to Work: Alloys of Gold"). Other common alloys are described in **Table 12.2**.

Table 12.2 Some Common Alloys

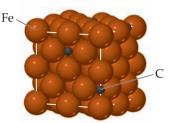

Name	Primary Element	Typical Composition (by Mass)	Properties	Uses
Wood's metal	Bismuth	50% Bi, 25% Pb, 12.5% Sn, 12.5% Cd	Low melting point (70 °C)	Fuse plugs, automatic sprinklers
Yellow brass	Copper	67% Cu, 33% Zn	Ductile, takes polish	Hardware items
Bronze	Copper	88% Cu, 12% Sn	Tough and chemically stable in dry air	Important alloy for early civilizations
Stainless steel	Iron	80.6% Fe, 0.4% C, 18% Cr, 1% Ni	Resists corrosion	Cookware, surgical instruments
Plumber's solder	Lead	67% Pb, 33% Sn	Low melting point (275 °C)	Soldering joints
Sterling silver	Silver	92.5% Ag, 7.5% Cu	Bright surface	Tableware
Dental amalgam	Silver	70% Ag, 18% Sn, 10% Cu, 2% Hg	Easily worked	Dental fillings
Pewter	Tin	92% Sn, 6% Sb, 2% Cu	Low melting point (230 °C)	Dishes, jewelry

A GO FIGURE

What determines which species in a solid solution is the solute and which is the solvent?

Interstitial alloy Steel

▲ Figure 12.15 The distribution of solute and solvent atoms in a substitutional alloy and an interstitial alloy. Both types of alloys are solid solutions and, therefore, homogeneous mixtures.

Alloys can be divided into four categories: substitutional alloys, interstitial alloys, heterogeneous alloys, and intermetallic compounds. Substitutional and interstitial alloys are both homogeneous mixtures in which components are dispersed randomly and uniformly (▲ Figure 12.15). ∞ (Section 1.2) Solids that form homogeneous mixtures are called solid solutions. When atoms of the solute in a solid solution occupy positions normally occupied by a solvent atom, we have a substitutional alloy. When the solute atoms occupy interstitial positions in the "holes" between solvent atoms, we have an **interstitial alloy** (Figure 12.15).

Substitutional alloys are formed when the two metallic components have similar atomic radii and chemical-bonding characteristics. For example, silver and gold form such an alloy over the entire range of possible compositions. When two metals differ in radii by more than about 15%, solubility is generally more limited.

For an interstitial alloy to form, the solute atoms must have a much smaller bonding atomic radius than the solvent atoms. Typically, the interstitial element is a nonmetal that makes covalent bonds to the neighboring metal atoms. The presence of the extra bonds provided by the interstitial component causes the metal lattice to become harder, stronger, and less ductile. For example, steel, which is much harder and stronger than pure iron, is an alloy of iron that contains up to 3% carbon. Other elements may be added to form alloy steels. Vanadium and chromium may be added to impart strength, for instance, and to increase resistance to fatigue and corrosion.

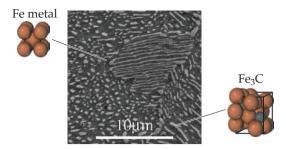

Give It Some Thought

Would you expect the alloy PdB_{0.15} to be a substitutional alloy or an interstitial alloy?

One of the most important iron alloys is stainless steel, which contains about 0.4% carbon, 18% chromium, and 1% nickel. The chromium is obtained by carbon reduction of chromite (FeCr₂O₄) in an electric furnace. The product of the reduction is ferrochrome (FeCr₂), which is added in the appropriate amount to molten iron to achieve the desired steel composition. The ratio of elements present in the steel may vary over a wide range, imparting a variety of specific physical and chemical properties to the materials.

In a heterogeneous alloy the components are not dispersed uniformly. For example, the heterogeneous alloy pearlite contains two phases (> Figure 12.16). One phase is essentially pure body-centered cubic iron, and the other is the compound Fe₃C,

▲ Figure 12.16 Microscopic view of the structure of the heterogeneous alloy pearlite.

The dark regions are body-centered cubic iron metal, and the lighter regions are cementite, Fe₃C.

known as cementite. In general, the properties of heterogeneous alloys depend on both the composition and the manner in which the solid is formed from the molten mixture. The properties of a heterogeneous alloy formed by rapid cooling of a molten mixture, for example, are distinctly different from the properties of an alloy formed by slow cooling of the same mixture.

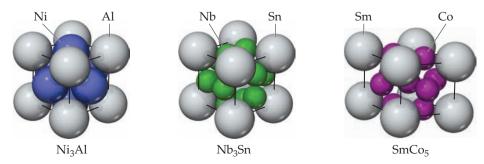

Intermetallic compounds are compounds rather than mixtures. Because they are compounds, they have definite properties and their composition cannot be varied. Furthermore, the different types of atoms in an intermetallic compound are ordered rather than randomly distributed. The ordering of atoms in an intermetallic compound generally leads to better structural stability and higher melting points than what is observed in the constituent metals. These features can be attractive for high-temperature applications. On the negative side, intermetallic compounds are often more brittle than substitutional alloys.

Intermetallic compounds play many important roles in modern society. The intermetallic compound Ni₃Al is a major component of jet aircraft engines because of its strength at high temperature and its low density. Razor blades are often coated with Cr₃Pt, which adds hardness, allowing the blade to stay sharp longer. Both compounds have the structure shown on the left-hand side of ▼ Figure 12.17. The compound Nb₃Sn, also shown in Figure 12.17, is a superconductor, a substance that, when cooled below a critical temperature, conducts electricity with no resistance. In the case of Nb₃Sn superconductivity is observed only when the temperature falls below 18 K. Superconductors are used in the magnets in MRI scanners widely employed for medical imaging. (Section 6.7, "Nuclear Spin and Magnetic Resonance Imaging") The need to keep the magnets cooled to such a low temperature is part of the reason why MRI devices are expensive to operate. The hexagonal intermetallic compound SmCo₅, shown on the right-hand side of Figure 12.17, is used to make the permanent magnets found in lightweight headsets and high-fidelity speakers. A related compound with the same structure, LaNi₅, is used as the anode in nickel-metal hydride batteries.

Chemistry Put to Work

Alloys of Gold

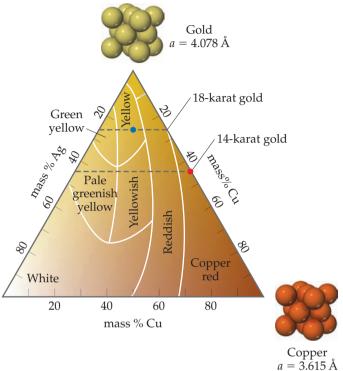

Gold has long been a metal of choice for decorative objects, jewelry, and coins. The popularity of gold is driven by its unusual color (for a metal), its resistance to many chemical reactions, and the fact that it can easily be worked. However, pure gold is too soft for many applications, including jewelry. To increase its strength and hardness, as well as to modify its color, gold is often alloyed with other metals. In the jewelry trade pure gold is termed 24 karat. The karat number decreases as the mass percent of gold decreases. The most common alloys used in jewelry are 14 karat, which is $(14/24) \times 100 = 58\%$ gold, and 18 karat, which is $(18/24) \times 100 = 75\%$ gold.

The color of gold varies depending on the metals it is alloyed with. Gold is typically alloyed with silver and/or copper. All three elements crystallize with a face-centered cubic structure. The fact that all three elements have similar radii (Au and Ag are nearly the same size; Cu is roughly 11% smaller) and crystallize with the same type of structure make it possible to form substitutional alloys with nearly any composition. The variations in color of these alloys as a function of composition are shown in

▶ Figure 12.18. Gold alloyed with equal parts silver and copper takes on the golden yellow color we associate with gold jewelry. Red or rose gold is a copperrich alloy. Silver-rich alloys take on a greenish hue, eventually giving way to silvery-white colors as silver becomes the majority constituent.

12.4 | Metallic Bonding

Consider the elements of the third period of the periodic table (Na–Ar). Argon with eight valence electrons has a complete octet; as a result it does not form any bonds. Chlorine, sulfur, and phosphorus form molecules (Cl_2 , S_8 , and P_4) in which the atoms make one, two, and three bonds, respectively (\triangleright Figure 12.19). Silicon forms an extended network solid in which each atom is bonded to four equidistant neighbors. Each of these elements forms 8 - N bonds, where N is the number of valence electrons. This behavior can easily be understood through the application of the octet rule.

If the 8-N trend continued as we move left across the periodic table, we would expect aluminum (three valence electrons) to form five bonds. Like many other metals, however, aluminum adopts a close-packed structure with 12 nearest neighbors. Magnesium and sodium also adopt metallic structures. What is responsible for this abrupt change in the preferred bonding mechanism? The answer, as noted earlier, is that metals do not have enough valence-shell electrons to satisfy their bonding requirements by forming localized electron-pair bonds. In response to this deficiency, the valence electrons are collectively shared. A structure in which the atoms are close-packed facilitates this delocalized sharing of electrons.

Electron-Sea Model

A simple model that accounts for some of the most important characteristics of metals is the **electron-sea model**, which pictures the metal as an array of metal cations in a "sea" of valence electrons (**> Figure 12.20**). The electrons are confined to the metal by electrostatic attractions to the cations, and they are uniformly distributed throughout the structure.

▲ Figure 12.19 Bonding in period 3 elements.

The electrons are mobile, however, and no individual electron is confined to any particular metal ion. When a voltage is applied to a metal wire, the electrons, being negatively charged, flow through the metal toward the positively charged end of the wire.

The high thermal conductivity of metals is also accounted for by the presence of mobile electrons. The movement of electrons in response to temperature gradients permits ready transfer of kinetic energy throughout the solid.

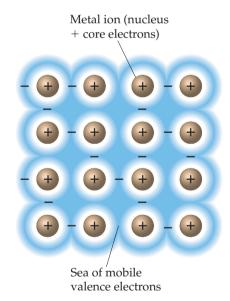

The ability of metals to deform (their malleability and ductility) can be explained by the fact that metal atoms form bonds to many neighbors. Changes in the positions of the atoms brought about in reshaping the metal are partly accommodated by a redistribution of electrons.

Molecular-Orbital Model

Although the electron-sea model works surprisingly well given its simplicity, it does not adequately explain many properties of metals. According to the model, for example, the strength of bonding between metal atoms should steadily increase as the number of valence electrons increases, resulting in a corresponding increase in the melting points. However, elements near the middle of the transition metal series, rather than those at the end, have the highest melting points in their respective periods (Figure 12.21). This trend implies that the strength of metallic bonding first increases with increasing number of electrons and then decreases. Similar trends are seen in other physical properties of the metals, such as the boiling point, heat of fusion, and hardness.

To obtain a more accurate picture of the bonding in metals, we must turn to molecular orbital theory. In Sections 9.7 and 9.8 we learned how molecular orbitals are created from the overlap of atomic orbitals. Let's briefly review some of the rules of molecular orbital theory:

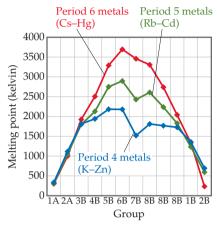

- Atomic orbitals combine to make molecular orbitals that can extend over the entire molecule.
- 2. A molecular orbital can contain zero, one, or two electrons.
- **3.** The number of molecular orbitals in a molecule equals the number of atomic orbitals that combine to form molecular orbitals.
- **4.** Adding electrons to a bonding molecular orbital strengthens bonding, while adding electrons to antibonding molecular orbitals weakens bonding.

▲ Figure 12.20 Electron-sea model of metallic bonding. The valence electrons delocalize to form a sea of mobile electrons that surrounds and binds together an extended array of metal ions.

GO FIGURE

Which element in each period has the highest melting point? In each case, is the element you named at the beginning, middle, or end of its period?

▲ Figure 12.21 The melting points of metals from periods 4, 5, and 6.

The electronic structures of crystalline solids and small molecules have similarities as well as differences. To illustrate, consider how the molecular-orbital diagram for a chain of lithium atoms changes as we increase the length of the chain (∇ Figure 12.22). Each lithium atom contains a half-filled 2s orbital in its valence shell. The molecular-orbital diagram for Li₂ is analogous to that of an H₂ molecule: one filled bonding molecular orbital and one empty antibonding molecular orbital with a nodal plane between the atoms. ∞ (Section 9.7) For Li₄, there are four molecular orbitals, ranging from the lowest-energy orbital, where the orbital interactions are completely bonding (zero nodal planes), to the highest-energy orbital, where all interactions are antibonding (three nodal planes).

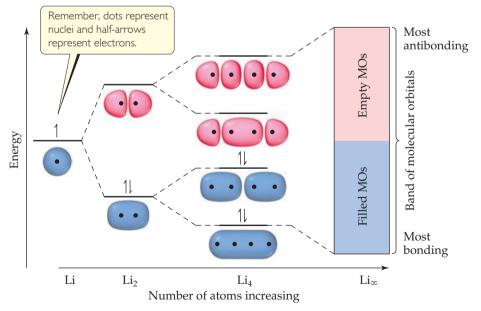

As the length of the chain increases, the number of molecular orbitals increases. Regardless of chain length, the lowest-energy orbitals are always the most bonding and the highest-energy orbitals always the most antibonding. Furthermore, because each lithium atom has only one valence shell atomic orbital, the number of molecular orbitals is equal to the number of lithium atoms in the chain. Because each lithium atom has one valence electron, half of the molecular orbitals are fully occupied and the other half are empty, regardless of chain length.*

If the chain becomes very long, there are so many molecular orbitals that the energy separation between them becomes vanishingly small. As the chain length goes to infinity, the allowed energy states become a continuous **band**. For a crystal large enough to see with the eye (or even an optical microscope), the number of atoms is extremely large. Consequently, the electronic structure of the crystal is like that of the infinite chain, consisting of bands, as shown on the right-hand side of Figure 12.22.

The electronic structures of most metals are more complicated than those shown in Figure 12.22 because we have to consider more than one type of atomic orbital on each atom. Because each type of orbital can give rise to its own band, the electronic

GO FIGURE

How does the energy spacing between molecular orbitals change as the number of atoms in the chain increases?

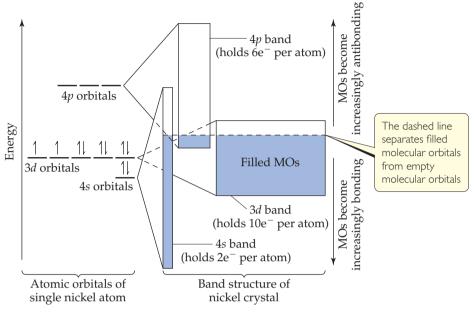

▲ Figure 12.22 Discrete energy levels in individual molecules become continuous energy bands in a solid. Occupied orbitals are shaded blue, and empty orbitals pink.

^{*}This is strictly true only for chains with an even number of atoms.

▲ GO FIGURE

If the metal were potassium rather than nickel, which bands—4s, 4p, and/or 3d—would be partially occupied?

▲ Figure 12.23 The electronic band structure of nickel.

structure of a solid usually consists of a series of bands. The electronic structure of a bulk solid is referred to as a **band structure**.

The band structure of a typical metal is shown schematically in \triangle Figure 12.23. The electron filling depicted corresponds to nickel metal, but the basic features of other metals are similar. The electron configuration of a nickel atom is $[Ar]4s^23d^8$, as shown on the left side of the figure. The energy bands that form from each of these orbitals are shown on the right side. The 4s, 4p, and 3d orbitals are treated independently, each giving rise to a band of molecular orbitals. In practice, these overlapping bands are not completely independent of each other, but for our purposes this simplification is reasonable.

The 4s, 4p, and 3d bands differ from one another in the energy range they span (represented by the heights of the rectangles on the right side of Figure 12.23) and in the number of electrons they can hold (represented by the area of the rectangles). The 4s, 4p, and 3d bands can hold 2, 6, and 10 electrons per atom, respectively, corresponding to two per orbital, as dictated by the Pauli exclusion principle. ∞ (Section 6.7) The energy range spanned by the 3d band is smaller than the range spanned by the 4s and 4p bands because the 3d orbitals are smaller and, therefore, overlap with orbitals on neighboring atoms less effectively.

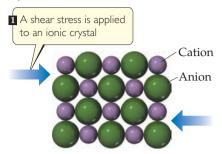

Many properties of metals can be understood from Figure 12.23. We can think of the energy band as a partially filled container for electrons. The incomplete filling of the energy band gives rise to characteristic metallic properties. The electrons in orbitals near the top of the occupied levels require very little energy input to be "promoted" to higher-energy orbitals that are unoccupied. Under the influence of any source of excitation, such as an applied electrical potential or an input of thermal energy, electrons move into previously vacant levels and are thus freed to move through the lattice, giving rise to electrical and thermal conductivity.

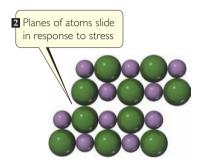

Without the overlap of energy bands, the periodic properties of metals could not be explained. In the absence of the d- and p-bands, we would expect the s-band to be half-filled for the alkali metals (group 1A) and completely filled for the alkaline-earth metals (group 2A). If that were true, metals like magnesium, calcium, and strontium

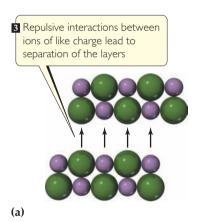

GO FIGURE

Why don't metals cleave in the way depicted here for ionic substances?

(h)

▲ Figure 12.24 Brittleness and faceting in ionic crystals. (a) When a shear stress (blue arrows) is applied to an ionic solid, the crystal separates along a plane of atoms as shown. (b) This property of ionic crystals is used to facet gemstones, such as rubies.

would not be good electrical and thermal conductors, in disagreement with experimental observations.

While the conductivity of metals can be qualitatively understood using either the electron–sea model or the molecular–orbital model, many physical properties of transition metals, such as the melting points plotted in Figure 12.21, can be explained only with the latter model. The molecular–orbital model predicts that bonding first becomes stronger as the number of valence electrons increases and the bonding orbitals are increasingly populated. Upon moving past the middle elements of the transition metal series, the bonds grow weaker as electrons populate antibonding orbitals. Strong bonds between atoms lead to metals with higher melting and boiling points, higher heats of fusion, higher hardness, and so forth.

Give It Some Thought

Which element, W or Au, has the greater number of electrons in antibonding orbitals? Which one would you expect to have the higher melting point?

12.5 | Ionic Solids

Ionic solids are held together by the electrostatic attraction between cations and anions: ionic bonds. ∞ (Section 8.2) The high melting and boiling points of ionic compounds are a testament to the strength of the ionic bonds. The strength of an ionic bond depends on the charges and sizes of the ions. As discussed in Chapters 8 and 11, the attractions between cations and anions increase as the charges of the ions increase. Thus NaCl, where the ions have charges of 1+ and 1−, melts at 801 °C, whereas MgO, where the ions have charges of 2+ and 2−, melts at 2852 °C. The interactions between cations and anions also increase as the ions get smaller, as we see from the melting points of the alkali metal halides in \blacktriangledown Table 12.3. These trends mirror the trends in lattice energy discussed in Section 8.2.

Although ionic and metallic solids both have high melting and boiling points, the differences between ionic and metallic bonding are responsible for important differences in their properties. Because the valence electrons in ionic compounds are confined to the anions, rather than being delocalized, ionic compounds are typically electrical insulators. They tend to be brittle, a property explained by repulsive interactions between ions of like charge. When stress is applied to an ionic solid, as in Figure 12.24, the planes of atoms, which before the stress were arranged with cations next to anions, shift so that the alignment becomes cation–cation, anion–anion. The resulting repulsive interaction causes the planes to split away from each other, a property that lends itself to the carving of certain gemstones (such as ruby, composed principally of Al_2O_3).

Structures of Ionic Solids

Like metallic solids, ionic solids tend to adopt structures with symmetric, close-packed arrangements of atoms. However, important differences arise because we now have to pack together spheres that have different radii and opposite charges. Because cations are often considerably smaller than anions ∞ (Section 7.3), the coordination numbers in ionic compounds are smaller than those in close-packed metals. Even if the

Table 12.3 Properties of the Alkali Metal Halides

Compound	Cation–Anion Distance (Å)	Lattice Energy (kJ/mol)	Melting Point (°C)
LiF	2.01	1030	845
NaCl	2.83	788	801
KBr	3.30	671	734
RbI	3.67	632	674

anions and cations were the same size, the close-packed arrangements seen in metals cannot be replicated without letting ions of like charge come in contact with each other. The repulsions between ions of the same type make such arrangements unfavorable. The most favorable structures are those where the cation-anion distances are as close as those permitted by ionic radii, but the anion-anion and cation-cation distances are maximized.

Give It Some Thought

Is it possible for all atoms in an ionic compound to lie on the lattice points as they do in the metallic structures shown in Figure 12.11?

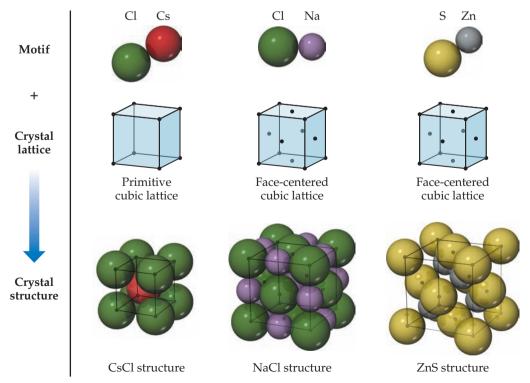

Three common ionic structure types are shown in ▼ Figure 12.25. The cesium chloride (CsCl) structure is based on a primitive cubic lattice. Anions sit on the lattice points at the corners of the unit cell, and a cation sits at the center of each cell. (Remember, there is no lattice point inside a primitive unit cell.) With this arrangement, both cations and anions are surrounded by a cube of eight ions of the opposite type.

The sodium chloride (NaCl; also called the rock salt structure) and zinc blende (ZnS) structures are based on a face-centered cubic lattice. In both structures the anions sit on the lattice points that lie on the corners and faces of the unit cell, but the two-atom motif is slightly different for the two structures. In NaCl the Na+ ions are displaced from the Cl ions along the edge of the unit cell, whereas in ZnS the Zn²⁺ ions are displaced from the S²⁻ ions along the body diagonal of the unit cell. This difference leads to different coordination numbers. In sodium chloride, each cation and each anion are surrounded by six ions of the opposite type, leading to an octahedral coordination environment. In zinc blende, each cation and

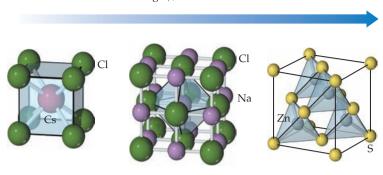

A GO FIGURE

Do the anions touch each other in any of these three structures? If not, which ions do touch each other?

▲ Figure 12.25 The structures of CsCl, NaCl, and ZnS. Each structure type can be generated by the combination of a two-atom motif and the appropriate lattice.

Decreasing r_+/r_-

	CsCl	NaCl	ZnS
Cation radius, r_+ (Å)	1.81	1.16	0.88
Anion radius, r_{-} (Å)	1.67	1.67	1.70
r_+/r	1.08	0.69	0.52
Cation coordination number	8	6	4
Anion coordination number	8	6	4

▲ Figure 12.26 Coordination environments in CsCl, NaCl, and ZnS. The sizes of the ions have been reduced to show the coordination environments clearly.

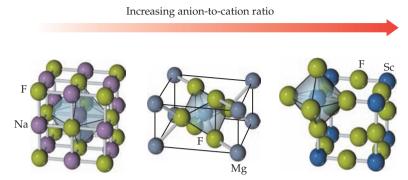

each anion are surrounded by four ions of the opposite type, leading to a tetrahedral coordination geometry. The cation coordination environments can be seen in Figure 12.26.

For a given ionic compound, we might ask which type of structure is most favorable. There are a number of factors that come into play, but two of the most important are the relative sizes of the ions and the stoichiometry. Consider first ion size. Notice in Figure 12.26 that the coordination number changes from 8 to 6 to 4 on moving from CsCl to NaCl to ZnS. This trend is driven in part by the fact that for these three compounds the ionic radius of the cation gets smaller while the ionic radius of the anion changes very little. When the cation and anion are similar in size, a large coordination number is favored and the CsCl structure is often realized. As the relative size of the cation gets smaller, eventually it is no longer possible to maintain the cation–anion contacts and simultaneously keep the anions from touching each other. When this occurs, the coordination number drops from 8 to 6, and the sodium chloride structure becomes more favorable. As the cation size decreases further, eventually the coordination number must be reduced again, this time from 6 to 4, and the zinc blende structure becomes favored. Remember that, in ionic crystals, ions of opposite charge touch each other but ions of the same charge should not touch.

The relative number of cations and anions also helps determine the most stable structure type. All the structures in Figure 12.26 have equal numbers of cations and anions. These structure types (cesium chloride, sodium chloride, zinc blende) can be realized only for ionic compounds in which the number of cations and anions is equal. When this is not the case, other crystal structures must result. As an example, consider NaF, MgF₂, and ScF₃ (**Figure 12.27**). Sodium fluoride has the sodium chloride structure with a coordination number of 6 for both cation and anion, as you might expect since NaF and NaCl are quite similar. Magnesium fluoride, however, has two anions for every cation, resulting in a tetragonal crystal structure called the *rutile structure*. The cation coordination number is still 6, but the fluoride coordination number is now only 3. In the scandium fluoride structure, there are three anions for every cation; the cation coordination number is still 6, but the fluoride coordination number has dropped to 2. As the cation/anion ratio goes down, there are fewer cations to surround each anion,

GO FIGURE

How many cations are there per unit cell for each of these structures? How many anions per unit cell?

	NaF	MgF_2	ScF ₃
Cation coordination number	6	6	6
Cation coordination geometry	Octahedral	Octahedral	Octahedral
Anion coordination number	6	3	2
Anion coordination geometry	Octahedral	Trigonal planar	Linear

▲ Figure 12.27 Coordination numbers depend on stoichiometry. The sizes of the ions have been reduced to show the coordination environments clearly.

and so the anion coordination number must decrease. The empirical formula of an ionic compound can be described quantitatively by the relationship

 $\frac{\text{Number of cations per formula unit}}{\text{Number of anions per formula unit}} = \frac{\text{anion coordination number}}{\text{cation coordination number}}$ [12.1]

Give It Some Thought

In the crystal structure of potassium oxide, the oxide ions are coordinated by eight potassium ions. What is the coordination number of potassium?

SAMPLE EXERCISE 12.2 Calculating the Density of an Ionic Solid

Rubidium iodide crystallizes with the same structure as sodium chloride. (a) How many iodide ions are there per unit cell? (b) How many rubidium ions are there per unit cell? (c) Use the ionic radii and molar masses of Rb $^+$ (1.66 Å, 85.47 g/mol) and I $^-$ (2.06 Å, 126.90 g/mol) to estimate the density of rubidium iodide in g/cm 3 .

SOLUTION

Analyze and Plan

- (a) We need to count the number of anions in the unit cell of the sodium chloride structure, remembering that ions on the corners, edges, and faces of the unit cell are only partially inside the unit cell.
- (b) We can apply the same approach to determine the number of cations in the unit cell. We can double-check our answer by writing the empirical formula to make sure the charges of the cations and anions are balanced.
- (c) Because density is an intensive property, the density of the unit cell is the same as the density of a bulk crystal. To calculate the density we must divide the mass of the atoms per unit cell by the

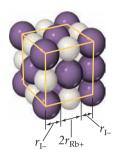

volume of the unit cell. To determine the volume of the unit cell we need to estimate the length of the unit cell edge by first identifying the direction along which the ions touch and then using ionic radii to estimate the length. Once we have the length of the unit cell edge we can cube it to determine its volume.

Solve

(a) The crystal structure of rubidium iodide looks just like NaCl with Rb⁺ ions replacing Na⁺ and I⁻ ions replacing Cl⁻. From the views of the NaCl structure in Figures 12.25 and 12.26 we see that there is an anion at each corner of the unit cell and at the center of each face. From Table 12.1 we see that the ions sitting on the corners are equally shared by eight unit cells (1/8 ion per unit cell), while those ions sitting on the faces are equally shared by two unit cells

(1/2 ion per unit cell). A cube has eight corners and six faces, so the total number of I^- ions is 8(1/8)+6(1/2)=4 per unit cell.

- (b) Using the same approach for the rubidium cations we see that there is a rubidium ion on each edge and one at the center of the unit cell. Using Table 12.1 again we see that the ions sitting on the edges are equally shared by four unit cells (1/4 ion per unit cell), whereas the cation at the center of the unit cell is not shared. A cube has 12 edges, so the total number of rubidium ions is 12(1/4)+1=4. This answer makes sense because the number of Rb $^{+}$ ions must be the same as the number of I $^{-}$ ions to maintain charge balance.
- (c) In ionic compounds cations and anions touch each other. In RbI the cations and anions touch along the edge of the unit cell as shown in the following figure.

The distance the unit cell edge is equal to $r(\Gamma) + 2r(Rb^+) + r(\Gamma) = 2r(\Gamma) + 2r(Rb^+)$. Plugging in the ionic radii we get 2(2.06 Å) + 2(1.66 Å) = 7.44 Å. The volume of a cubic unit cell is just the edge length cubed. Converting from Å to cm and cubing we get

Volume =
$$(7.44 \times 10^{-8} \text{ cm})^3 = 4.12 \times 10^{-22} \text{ cm}^3$$
.

From parts (a) and (b) we know that there are four rubidium and four iodide ions per unit cell. Using this result and the molar masses we can calculate the mass per unit cell

$$Mass = \frac{4(85.47 \text{ g/mol}) + 4(126.90 \text{ g/mol})}{6.022 \times 10^{23} \text{mol}^{-1}} = 1.411 \times 10^{-21} \text{ g}$$

The density is the mass per unit cell divided by the volume of a unit cell

Density =
$$\frac{mass}{volume}$$
 = $\frac{1.411 \times 10^{-21} \text{ g}}{4.12 \times 10^{-22} \text{ cm}^3}$ = 3.43 g/cm³

Check The densities of most solids fall between the density of lithium $(0.5~g/cm^3)$ and that of iridium $(22.6~g/cm^3)$, so this value is reasonable.

Practice Exercise 1

Given the ionic radii and molar masses of Sc^{3+} (0.88 Å, 45.0 g/mol) and F⁻ (1.19 Å, 19.0 g/mol) what value do you estimate for the density of ScF_3 , whose structure is shown in Figure 12.27? (a) 5.99 g/cm³, (b) 1.44×10^{24} g/mol, (c) 19.1 g/cm³, (d) 2.39 g/cm³, (e) 5.72 g/cm³.

Practice Exercise 2

Estimate the length of the cubic unit cell edge and the density of CsCl (Figure 12.25) from the ionic radii of cesium, 1.81 Å, and chloride, 1.67 Å. (*Hint*: Ions in CsCl touch along the body diagonal, a vector running from one corner of a cube through the body center to the opposite corner. Using trigonometry it can be shown that the body diagonal of a cube is $\sqrt{3}$ times longer than the edge.)

12.6 | Molecular Solids

Molecular solids consist of atoms or neutral molecules held together by dipole–dipole forces, dispersion forces, and/or hydrogen bonds. Because these intermolecular forces are weak, molecular solids are soft and have relatively low melting points (usually below 200 $^{\circ}$ C). Most substances that are gases or liquids at room temperature form molecular solids at low temperature. Examples include Ar, H₂O, and CO₂.

The properties of molecular solids depend in large part on the strengths of the forces between molecules. Consider, for example, the properties of sucrose (table sugar,

 $C_{12}H_{22}O_{11}$). Each sucrose molecule has eight —OH groups, which allow for the formation of multiple hydrogen bonds. Consequently, sucrose exists as a crystalline solid at room temperature, and its melting point, 184 °C, is relatively high for a molecular solid.

Molecular shape is also important because it dictates how efficiently molecules pack together in three dimensions. Benzene (C_6H_6) , for example, is a highly symmetrical planar molecule. ∞ (Section 8.6) It has a higher melting point than toluene, a compound in which one of the hydrogen atoms of benzene has been replaced by a CH_3 group (\P Figure 12.28). The lower symmetry of toluene molecules prevents them from packing in a crystal as efficiently as benzene molecules. As a result, the intermolecular forces that depend on close contact are not as effective and the melting point is lower. In contrast, the boiling point of toluene is *higher* than that of benzene, indicating that the intermolecular attractive forces are larger in liquid toluene than in liquid benzene. The melting and boiling points of phenol, another substituted benzene shown in Figure 12.28, are higher than those of benzene because the OH group of phenol can form hydrogen bonds.

GO FIGURE

In which substance, benzene or toluene, are the intermolecular forces stronger? In which substance do the molecules pack more efficiently?

▲ Figure 12.28 Melting and boiling points for benzene, toluene, and phenol.

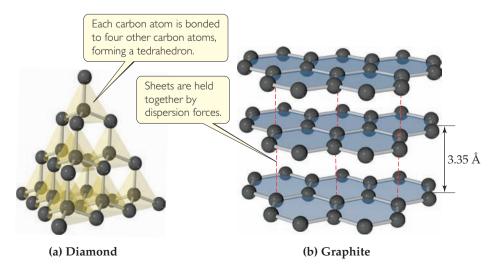

12.7 | Covalent-Network Solids

Covalent-network solids consist of atoms held together in large networks by covalent bonds. Because covalent bonds are much stronger than intermolecular forces, these solids are much harder and have higher melting points than molecular solids. Diamond and graphite, two allotropes of carbon, are two of the most familiar covalent-network solids. Other examples are silicon, germanium, quartz (SiO₂), silicon carbide (SiC), and boron nitride (BN). In all cases, the bonding between atoms is either completely covalent or more covalent than ionic.

In diamond, each carbon atom is bonded tetrahedrally to four other carbon atoms (∇ Figure 12.29). The structure of diamond can be derived from the zinc blende structure (Figure 12.26) if carbon atoms replace both the zinc and sulfide ions. The carbon atoms are sp^3 -hybridized and held together by strong carbon-carbon single covalent bonds. The strength and directionality of these bonds make diamond the hardest known material. For this reason, industrial-grade diamonds are employed in saw blades used for the most demanding cutting jobs. The stiff, interconnected bond network also explains why diamond is one of the best-known thermal conductors, yet is not electrically conductive. Diamond has a high melting point, 3550 °C.

In graphite, [Figure 12.29(b)], the carbon atoms form covalently bonded layers that are held together by intermolecular forces. The layers in graphite are the same as those in the graphene sheet shown in Figure 12.8. Graphite has a hexagonal unit cell containing two layers offset so that the carbon atoms in a given layer sit over the middle of the hexagons of the layer below. Each carbon is covalently bonded to three other carbons in the same layer to form interconnected hexagonal rings. The distance between adjacent carbon atoms in the plane, 1.42 Å, is very close to the C—C distance in benzene, 1.395 Å. In fact, the bonding resembles that of benzene, with delocalized π bonds extending over the layers. ∞ (Section 9.6) Electrons move freely through the delocalized orbitals, making graphite a good electrical conductor along the layers. (In fact, graphite is used as a conducting electrode in batteries.) These sp^2 -hybridized sheets of carbon atoms are separated by 3.35 Å from one another, and the sheets are held together only by dispersion forces. Thus, the layers readily slide past one another when rubbed, giving graphite a greasy feel. This tendency is enhanced when impurity atoms are trapped between the layers, as is typically the case in commercial forms of the material.

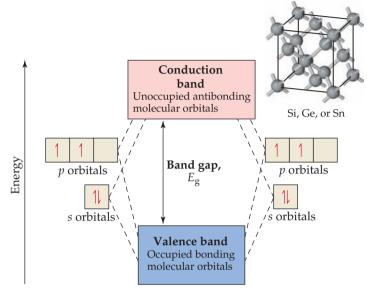

Graphite is used as a lubricant and as the "lead" in pencils. The enormous differences in physical properties of graphite and diamond—both of which are pure carbon—arise from differences in their three-dimensional structure and bonding.

▲ Figure 12.29 The structures of (a) diamond and (b) graphite.

GO FIGURE

If you draw a second diagram next to this one to represent an insulator, what aspect of the second diagram would be different?

▲ Figure 12.30 The electronic band structure of semiconductors that have the diamond crystal structure.

Semiconductors

Metals conduct electricity extremely well. Many solids, however, conduct electricity somewhat, but nowhere near as well as metals, which is why such materials are called **semiconductors**. Two examples of semiconductors are silicon and germanium, which lie immediately below carbon in the periodic table. Like carbon, each of these elements has four valence electrons, just the right number to satisfy the octet rule by forming single covalent bonds with four neighbors. Hence, silicon and germanium, as well as the gray form of tin, crystallize with the same infinite network of covalent bonds as diamond.

When atomic s and p orbitals overlap, they form bonding molecular orbitals and antibonding molecular orbitals. Each pair of s orbitals overlaps to give one bonding and one antibonding molecular orbital, whereas the p orbitals overlap to give three bonding and three antibonding molecular orbitals. (Section 9.8) The extended network of bonds leads to the formation of the same type of bands we saw for metals in Section 12.4. However, unlike metals, in semiconductors an energy gap develops between the filled and empty states, much like the energy gap between bonding and antibonding orbitals. (Section 9.6) The band that forms from bonding molecular orbitals is called the valence band, and the band that forms the antibonding orbitals is called the conduction band (Figure 12.30). In a semiconductor, the valence band is filled with electrons and the conduction band is empty. These two bands are separated by the energy band gap E_g . In the semiconductor community, energies are given in electron

volts (eV); $1 \text{ eV} = 1.602 \times 10^{-19} \text{J}$. Band gaps greater than $\sim 3.5 \text{ eV}$ are so large that the material is not a semiconductor; it is an **insulator** and does not conduct electricity at all.

Semiconductors can be divided into two classes, elemental semiconductors, which contain only one type of atom, and compound semiconductors, which contain two or more elements. The elemental semiconductors all come from group 4A. As we move down the periodic table, bond distances increase, which decreases orbital overlap. This decrease in overlap reduces the energy difference between the top of the valence band and the bottom of the conduction band. As a result, the band gap decreases on going from diamond (5.5 eV, an insulator) to silicon (1.11 eV) to germanium (0.67 eV) to gray tin (0.08 eV). In the heaviest group 4A element, lead, the band gap collapses altogether. As a result, lead has the structure and properties of a metal.

Compound semiconductors maintain the same *average* valence electron count as elemental semiconductors—four per atom. For example, in gallium arsenide, GaAs, each Ga atom contributes three electrons and each As atom contributes five, which averages out to four per atom—the same number as in silicon or germanium. Hence, GaAs is a semiconductor. Other examples are InP, where indium contributes three valence electrons and phosphorus contributes five, and CdTe, where cadmium provides two valence electrons and tellurium contributes six. In both cases, the average is again four valence electrons per atom. GaAs, InP, and CdTe all crystallize with a zinc blende structure.

There is a tendency for the band gap of a compound semiconductor to increase as the difference in group numbers increases. For example, $E_{\rm g}=0.67\,{\rm eV}$ in Ge, but $E_{\rm g}=1.43\,{\rm eV}$ in GaAs. If we increase the difference in group number to four, as in ZnSe (groups 2B and 6A), the band gap increases to 2.70 eV. This progression is a result of the transition from pure covalent bonding in elemental semiconductors to polar covalent bonding in compound semiconductors. As the difference in electronegativity of the elements increases, the bonding becomes more polar and the band gap increases.

Electrical engineers manipulate both the orbital overlap and the bond polarity to control the band gaps of compound semiconductors for use in a wide range of electrical and optical devices. The band gaps of several elemental and compound semiconductors are given in Table 12.4.

Table 12.4	Band C	Gaps of	Select	Elemental	and	Compound	Semiconductors
------------	--------	---------	--------	------------------	-----	----------	----------------

Material	Structure Type	$E_{\mathbf{g'}}\mathrm{eV}^\dagger$					
Si	Diamond	1.11		13	14	15	l
AlP	Zinc blende	2.43		Al	Si	P	
Ge	Diamond	0.67	30	31	32	33	34
GaAs	Zinc blende	1.43	Zn	Ga	Ge	As	Se
ZnSe	Zinc blende	2.58	48	49	50	51	52
CuBr	Zinc blende	3.05	Cd	In	Sn	Sb	Te
Sn [‡]	Diamond	0.08					
InSb	Zinc blende	0.18					
CdTe	Zinc blende	1.50					

[†] Band gap energies are room temperature values, $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}.$

SAMPLE EXERCISE 12.3

Qualitative Comparison of Semiconductor Band Gaps

Will GaP have a larger or smaller band gap than ZnS? Will it have a larger or smaller band gap than GaN?

SOLUTION

Analyze The size of the band gap depends on the vertical and horizontal positions of the elements in the periodic table. The band gap will increase when either of the following conditions is met: (1) The elements are located higher up in the periodic table, where enhanced orbital overlap leads to a larger splitting between bonding and antibonding orbital energies, or (2) the horizontal separation between the elements increases, which leads to an increase in the electronegativity difference and bond polarity.

Plan We must look at the periodic table and compare the relative positions of the elements in each case.

Solve Gallium is in the fourth period and group 3A. Phosphorus is in the third period and group 5A. Zinc and sulfur are in the same periods as gallium and phosphorus, respectively. However, zinc, in group 2B, is one element to the left of gallium; sulfur in group 6A is one element to the right of phosphorus. Thus, we would expect the electronegativity difference to be larger for ZnS, which should result in ZnS having a larger band gap than GaP.

For both GaP and GaN the more electropositive element is gallium. So we need only compare the positions of the more electronegative elements, P and N. Nitrogen is located above phosphorus in group 5A. Therefore, based on increased orbital overlap, we would expect GaN to have a larger band gap than GaP.

Check External references show that the band gap of GaP is 2.26 eV, ZnS is 3.6 eV, and GaN is 3.4 eV.

Practice Exercise 1

Which of these statements is false?

(a) As you go down column 4A in the periodic table, the elemental solids become more electrically conducting. (b) As you go down column 4A in the periodic table, the band gaps of the elemental solids decrease. (c) The valence electron count for a compound semiconductor averages out to four per atom. (d) Band gap energies of semiconductors range from ~0.1 to 3.5 eV. (e) In general, the more polar the bonds are in compound semiconductors, the smaller the band gap.

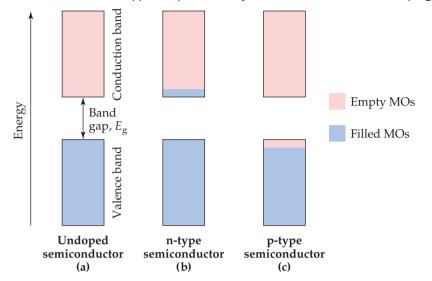

Practice Exercise 2

Will ZnSe have a larger or smaller band gap than ZnS?

[‡] These data are for gray tin, the semiconducting allotrope of tin. The other allotrope, white tin, is a metal.

▲ GO FIGURE

Predict what would happen in panel (b) if you doubled the amount of doping shown in the n-type semiconductor.

▲ Figure 12.31 The addition of small amounts of impurities (doping) to a semiconductor changes the electronic properties of the material.

Semiconductor Doping

The electrical conductivity of a semiconductor is influenced by the presence of small numbers of impurity atoms. The process of adding controlled amounts of impurity atoms to a material is known as **doping**. Consider what happens when a few phosphorus atoms (known as dopants) replace silicon atoms in a silicon crystal. In pure Si all of the valence-band molecular orbitals are filled and all of the conduction-band molecular orbitals are empty, as \blacktriangle Figure 12.31(a) shows. Because phosphorus has five valence electrons but silicon has only four, the "extra" electrons that come with the dopant phosphorus atoms are forced to occupy the conduction band [Figure 12.31(b)]. The doped material is called an *n-type* semiconductor, *n* signifying that the number of *n*egatively charged electrons in the conduction band has increased. These extra electrons can move very easily in the conduction band. Thus, just a few parts per million (ppm) of phosphorus in silicon can increase silicon's intrinsic conductivity by a factor of a million!

The dramatic change in conductivity in response to the addition of a trace amount of a dopant means that extreme care must be taken to control the impurities in semiconductors. The semiconductor industry uses "nine-nines" silicon to make integrated circuits; what this means is that Si must be 99.9999999999 pure (nine nines after the decimal place) to be technologically useful! Doping provides an opportunity for controlling the electrical conductivity through precise control of the type and concentration of dopants.

It is also possible to dope semiconductors with atoms that have fewer valence electrons than the host material. Consider what happens when a few aluminum atoms replace silicon atoms in a silicon crystal. Aluminum has only three valence electrons compared to silicon's four. Thus, there are electron vacancies, known as **holes**, in the valence band when silicon is doped with aluminum [Figure 12.31(c)]. Since the negatively charged electron is not there, the hole can be thought of as having a positive charge. Any adjacent electron that jumps into the hole leaves behind a new hole. Thus, the positive hole moves about in the lattice like a particle.* A material like this is called

^{*}This movement is analogous to watching people changing seats in a classroom; you can watch the people (electrons) move about the seats (atoms), or you can watch the empty seats (holes) "move."

a *p-type* semiconductor, *p* signifying that the number of *p*ositive holes in the material has increased.

As with n-type conductivity, p-type dopant levels of only parts per million can lead to a millionfold increase in conductivity—but in this case, the holes in the valence band are doing the conduction [Figure 12.31(c)].

The junction of an n-type semiconductor with a p-type semiconductor forms the basis for diodes, transistors, solar cells, and other devices.

SAMPLE EXERCISE 12.4 Identifying Types of Semiconductors

Which of the following elements, if doped into silicon, would yield an n-type semiconductor: Ga, As, or C?

SOLUTION

Analyze An n-type semiconductor means that the dopant atoms must have more valence electrons than the host material. Silicon is the host material in this case.

Plan We must look at the periodic table and determine the number of valence electrons associated with Si, Ga, As, and C. The elements with more valence electrons than silicon are the ones that will produce an n-type material upon doping.

Solve Si is in column 4A, and so has four valence electrons. Ga is in column 3A, and so has three valence electrons. As is in column 5A, and so has five valence electrons; C is in column 4A, and so has four valence electrons. Therefore, As, if doped into silicon, would yield an n-type semiconductor.

Practice Exercise 1

Which of these doped semiconductors would yield a p-type material? (These choices are written as host atom: dopant atom.)

(a) Ge:P (b) Si:Ge (c) Si:Al (d) Ge:S (e) Si:N

Practice Exercise 2

Compound semiconductors can be doped to make n-type and p-type materials, but the scientist has to make sure that the proper atoms are substituted. For example, if Ge were doped into GaAs, Ge could substitute for Ga, making an n-type semiconductor; but if Ge substituted for As, the material would be p-type. Suggest a way to dope CdSe to create a p-type material.

12.8 | Polymers

In nature we find many substances of very high molecular weight, running up to millions of amu, that make up much of the structure of living organisms and tissues. Some examples are starch and cellulose, which abound in plants, as well as proteins, which are found in both plants and animals. In 1827 Jons Jakob Berzelius coined the word **polymer** (from the Greek *polys*, "many," and *meros*, "parts") to denote molecular substances of high molecular weight formed by the *polymerization* (joining together) of **monomers**, molecules with low molecular weight.

Historically natural polymers, such as wool, leather, silk, and natural rubber, were processed into usable materials. During the past 70 years or so, chemists have learned to form synthetic polymers by polymerizing monomers through controlled chemical reactions. A great many of these synthetic polymers have a backbone of carbon–carbon bonds because carbon atoms have an exceptional ability to form strong stable bonds with one another.

Chemistry Put to Work

Solid-State Lighting

Artificial lighting is so widespread we take it for granted. Major savings in energy would be realized if incandescent lights can be replaced by light-emitting diodes (LEDs). Because LEDs are made from semiconductors, this is an appropriate place to take a closer look at the operation of an LED.

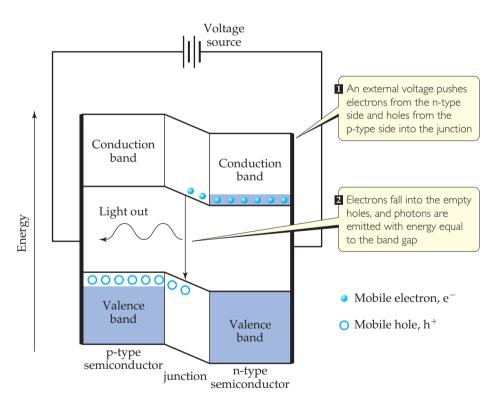

The heart of an LED is a p-n diode, which is formed by bringing an n-type semiconductor into contact with a p-type semiconductor. In the junction where they meet there are very few electrons or holes to carry the charge across the interface between them, and the conductivity decreases. When an appropriate voltage is applied, electrons are driven from the conduction band of the n-doped side into the junction, where they meet holes that have been driven from the valence band of the p-doped side. The electrons fall into the empty holes, and their energy is converted into light whose photons have energy equal to the band gap (▼ Figure 12.32). In this way electrical energy is converted into optical energy.

Because the wavelength of light that is emitted depends on the band gap of the semiconductor, the color of light produced by the LED can be controlled by appropriate choice of semiconductor. Most red LEDs are made of a mixture of GaP and GaAs. The band gap of GaP is 2.26 eV (3.62×10^{-19} J), which corresponds to a green photon with a wavelength of 549 nm, while GaAs has a band gap of 1.43 eV (2.29×10^{-19} J), which corresponds to an infrared photon with a wavelength of 867 nm. (Sections 6.1 and 6.2) By forming solid solutions of these two compounds, with stoichiometries of $GaP_{1-x}As_x$, the band gap can be adjusted to any intermediate value. Thus, $GaP_{1-x}As_x$ is the solid solution of choice for red, orange, and yellow LEDs. Green LEDs are made from mixtures of GaP and AlP ($E_g = 2.43$ eV, $\lambda = 510$ nm).

Red LEDs have been in the market for decades, but to make white light, an efficient blue LED was needed. The first prototype bright blue LED was demonstrated in a Japanese laboratory in 1993. In 2010, less than 20 years later, over \$10 billion worth of blue LEDs were sold worldwide. The blue LEDs are based on combinations of GaN ($E_{\rm g}=3.4\,{\rm eV},\lambda=365\,{\rm nm}$) and InN ($E_{\rm g}=2.4\,{\rm eV},\lambda=517\,{\rm nm}$).

Many colors of LEDs are now available and are used in everything from barcode scanners to traffic lights (▼ Figure 12.33). Because the light emission results from semiconductor structures that can be made extremely small and because they emit little heat, LEDs are replacing standard incandescent and fluorescence light bulbs in many applications.

Plastics are polymeric solids that can be formed into various shapes, usually by the application of heat and pressure. There are several types of plastics. **Thermoplastics** can be reshaped. For example, plastic milk containers are made from the thermoplastic polymer *polyethylene*. These containers can be melted down and the polymer recycled for some other use. In contrast, a **thermosetting plastic** (also called a *thermoset*) is shaped through irreversible chemical processes and, therefore, cannot be reshaped readily. Another type of plastic is the **elastomer**, which is a material that exhibits

rubbery or elastic behavior. When subjected to stretching or bending, an elastomer regains its original shape upon removal of the distorting force, if it has not been distorted beyond some elastic limit. Rubber is the most familiar example of an elastomer.

Some polymers, such as nylon and polyesters, both of which are thermosetting plastics, can be formed into fibers that, like hair, are very long relative to their cross-sectional area. These fibers can be woven into fabrics and cords and fashioned into clothing, tire cord, and other useful objects.

Making Polymers

A good example of a polymerization reaction is the formation of polyethylene from ethylene molecules (▼ Figure 12.34). In this reaction, the double bond in each ethylene molecule "opens up," and two of the electrons originally in this bond are used to form new C — C single bonds with two other ethylene molecules. This type of polymerization, in which monomers are coupled through their multiple bonds, is called addition polymerization.

We can write the equation for the polymerization reaction as follows:

$$n \, \mathrm{CH}_2 = \mathrm{CH}_2 \longrightarrow \begin{bmatrix} \mathrm{H} & \mathrm{H} \\ | & | \\ \mathrm{C} - \mathrm{C} \\ | & | \\ \mathrm{H} & \mathrm{H} \end{bmatrix}_n$$

Here *n* represents the large number—ranging from hundreds to many thousands—of monomer molecules (ethylene in this case) that react to form one polymer molecule. Within the polymer, a repeat unit (the unit shown in brackets in the previous equation) appears over and over along the entire chain. The ends of the chain are capped by carbon–hydrogen bonds or by some other bond, so that the end carbons have four bonds.

Polyethylene is an important material; its annual production exceeds 170 billion pounds each year. Although its composition is simple, the polymer is not easy to make. The right manufacturing conditions were identified only after many years of research. Today many forms of polyethylene, varying widely in physical properties, are known.

Polymers of other chemical compositions provide still greater variety in physical and chemical properties. **Table 12.5** lists several other common polymers obtained by addition polymerization.

A second general reaction used to synthesize commercially important polymers is **condensation polymerization**. In a condensation reaction two molecules are joined to form a larger molecule by elimination of a small molecule, such as H_2O . For example, an amine (a compound containing $-NH_2$) reacts with a carboxylic acid

Recycling Plastics

If you look at the bottom of a plastic container, you are likely to see a recycle symbol containing a number, as shown in ▼ Figure 12.36. The number and the letter abbreviation below it indicate the kind

of polymer from which the container is made, as summarized in ▼ Table 12.6. (The chemical structures of these polymers are shown in Table 12.5.) These symbols make it possible to sort containers by composition. In general, the lower the number, the greater the ease with which the material can be recycled.

➤ Figure 12.36 Recycling symbols. Most plastic containers manufactured today carry a recycling symbol indicating the type of polymer used to make the container and the polymer's suitability for recycling.

Table 12.6 Categories Used for Recycling Polymeric Materials in the United States

end, is reacted with a *diacid*, a compound with the —COOH group at each end. For example, the copolymer nylon 6,6 is formed when a diamine that has six carbon atoms and an amino group on each end is reacted with adipic acid, which also has six carbon atoms (▼ Figure 12.37). A condensation reaction occurs on each end of the diamine and the acid. Water is released, and N—C bonds are formed between molecules.

Table 12.5 lists nylon 6,6 and some other common polymers obtained by condensation polymerization. Notice that these polymers have backbones containing N or O atoms as well as C atoms.

▲ Figure 12.37 The formation of the copolymer nylon 6,6.

Give It Some Thought

Is this molecule a better starting material for an addition polymer or a condensation polymer?

Structure and Physical Properties of Polymers

The simple structural formulas given for polyethylene and other polymers are deceptive. Because four bonds surround each carbon atom in polyethylene, the atoms are arranged in a tetrahedral fashion, so that the chain is not straight as we have depicted it. Furthermore, the atoms are relatively free to rotate around the C—C single bonds. Rather than being straight and rigid, therefore, the chains are flexible, folding readily

▲ Figure 12.38 A segment of a polyethylene chain. This segment consists of 28 carbon atoms. In commercial polyethylenes, the chain lengths range from about 10³ to 10⁵ CH₂ units.

▲ Figure 12.39 Interactions between polymer chains. In the circled regions, the forces that operate between adjacent segments of the chains lead to ordering analogous to the ordering in crystals, though less regular.

(◀ Figure 12.38). The flexibility in the molecular chains causes any material made of this polymer to be very flexible.

Both synthetic and natural polymers commonly consist of a collection of *macromolecules* (large molecules) of different molecular weights. Depending on the conditions of formation, the molecular weights may be distributed over a wide range or may be closely clustered around an average value. In part because of this distribution in molecular weights, polymers are largely amorphous (noncrystalline) materials. Rather than exhibiting a well-defined crystalline phase with a sharp melting point, polymers soften over a range of temperatures. They may, however, possess shortrange order in some regions of the solid, with chains lined up in regular arrays as shown in \P Figure 12.39. The extent of such ordering is indicated by the degree of crystallinity of the polymer. Mechanical stretching or pulling to align the chains as the molten polymer is drawn through small holes can frequently enhance the crystallinity of a polymer. Intermolecular forces between the polymer chains hold the chains together in the ordered crystalline regions, making the polymer denser, harder, less soluble, and more resistant to heat. \P Table 12.7 shows how the properties of polyethylene change as the degree of crystallinity increases.

The linear structure of polyethylene is conducive to intermolecular interactions that lead to crystallinity. However, the degree of crystallinity in polyethylene strongly depends on the average molecular weight. Polymerization results in a mixture of macromolecules with varying values of n (numbers of monomer molecules) and, hence, varying molecular weights. Low-density polyethylene (LDPE), used in forming films and sheets, has an average molecular weight in the range of 10^4 amu, has a density of less than $0.94 \, \mathrm{g/cm^3}$, and has substantial chain branching. That is, there are side chains off the main chain of the polymer. These side chains inhibit the formation of crystalline regions, reducing the density of the material. High-density polyethylene (HDPE), used to form bottles, drums, and pipes, has an average molecular weight in the range of 10^6 amu and has a density of $0.94 \, \mathrm{g/cm^3}$ or higher. This form has fewer side chains and thus a higher degree of crystallinity.

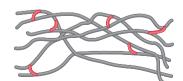

Polymers can be made stiffer by introducing chemical bonds between chains. Forming bonds between chains is called **cross-linking** (◀ Figure 12.40). The greater

Give It Some Thought

the number of cross-links, the more rigid the polymer. Whereas thermoplastic materials consist of independent polymer chains, thermosetting plastics become cross-linked when heated; the cross-links allow them to hold their shapes.

An important example of cross-linking is the **vulcanization** of natural rubber, a process discovered by Charles Goodyear in 1839. Natural rubber is formed from a liquid resin derived from the inner bark of the *Hevea brasiliensis* tree. Chemically, it is a polymer of isoprene, C_5H_8 (\triangle Figure 12.41). Because rotation about the carboncarbon double bond does not readily occur, the orientation of the groups bound to the carbons is rigid. In natural rubber, the chain extensions are on the same side of the double bond, as shown in Figure 12.41(a).

Natural rubber is not a useful polymer because it is too soft and too chemically reactive. Goodyear accidentally discovered that adding sulfur and then heating the mixture makes the rubber harder and reduces its susceptibility to oxidation and other chemical degradation reactions. The sulfur changes rubber into a thermosetting polymer by cross-linking the polymer chains through reactions at some of the double bonds, as shown schematically in Figure 12.41(b). Cross-linking of about 5% of the double bonds creates a flexible, resilient rubber. When the rubber is stretched, the cross-links help prevent the chains from slipping, so that the rubber retains its elasticity. Because heating was an important step in his process, Goodyear named it after Vulcan, the Roman god of fire.

Most polymers contain sp^3 -hybridized carbon atoms lacking delocalized π electrons ∞ (Section 9.6), so they are usually electrical insulators and are colorless (which implies a large band gap). However, if the backbone of the polymer has resonance ∞ (Sections 8.6 and 9.6), the electrons can become delocalized over long distances, which can lead to semiconducting behavior in the polymer. Such "plastic electronics" are of great current interest for lightweight and flexible organic solar cells, organic transistors, organic light-emitting diodes, and other

▲ Figure 12.42 Plastic electronics. Flexible organic solar cells are made from conducting polymers.

devices that are based on carbon rather than inorganic semiconductors like silicon (◀ Figure 12.42).

12.9 | Nanomaterials

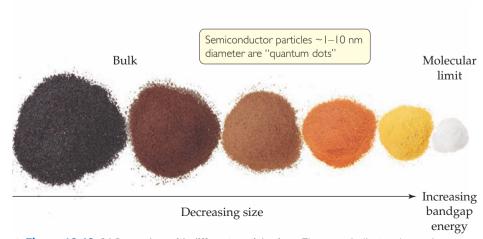

The prefix *nano* means 10^{-9} . ∞ (Section 1.4) When people speak of "nanotechnology," they usually mean making devices that are on the 1–100-nm scale. It turns out that the properties of semiconductors and metals change in this size range. **Nanomaterials**—materials that have dimensions on the 1–100-nm scale—are under intense investigation in research laboratories around the world, and chemistry plays a central role in this investigation.

Semiconductors on the Nanoscale

Figure 12.22 shows that, in small molecules, electrons occupy discrete molecular orbitals whereas in macroscale solids the electrons occupy delocalized bands. At what point does a molecule get so large that it starts behaving as though it has delocalized bands rather than localized molecular orbitals? For semiconductors, both theory and experiment tell us that the answer is roughly at 1 to 10 nm (about 10–100 atoms across). The exact number depends on the specific semiconductor material. The equations of quantum mechanics that were used for electrons in atoms can be applied to electrons (and holes) in semiconductors to estimate the size where materials undergo a crossover from molecular orbitals to bands. Because these effects become important at 1 to 10 nm, semiconductor particles with diameters in this size range are called *quantum dots*.

One of the most spectacular effects of reducing the size of a semiconductor crystal is that the band gap changes substantially with size in the 1–10-nm range. As the particle gets smaller, the band gap gets larger, an effect observable by the naked eye, as shown in \blacktriangledown Figure 12.43. On the macro level, the semiconductor cadmium phosphide looks black because its band gap is small ($E_{\rm g}=0.5\,{\rm eV}$), and it absorbs all wavelengths of visible light. As the crystals are made smaller, the material progressively changes color until it looks white! It looks white because now no visible light is absorbed. The band gap is so large that only high-energy ultraviolet light can excite electrons into the conduction band ($E_{\rm g}>3.0\,{\rm eV}$).

Making quantum dots is most easily accomplished using chemical reactions in solution. For example, to make CdS, you can mix Cd(NO₃)₂ and Na₂S in water. If you

 \triangle Figure 12.43 Cd₃P₂ powders with different particle sizes. The arrow indicates decreasing particle size and a corresponding increase in the band gap energy, resulting in different colors.

do not do anything else, you will precipitate large crystals of CdS. However, if you first add a negatively charged polymer to the water (such as polyphosphate, $-(OPO_2)_n$), the Cd^{2+} associates with the polymer, like tiny "meatballs" in the polymer "spaghetti." When sulfide is added, CdS particles grow, but the polymer keeps them from forming large crystals. A great deal of fine-tuning of reaction conditions is necessary to produce nanocrystals that are of uniform size and shape.

As we learned in Section 12.7, some semiconductor devices can emit light when a voltage is applied. Another way to make semiconductors emit light is to illuminate them with light whose photons have energies larger than the energy of the band gap of the semiconductor, a process called photoluminescence. A valence-band electron absorbs a photon and is promoted to the conduction band. If the excited electron then falls back down into the hole it left in the valence band, it emits a photon having energy equal to the band gap energy. In the case of quantum dots, the band gap is tunable with the crystal size, and thus all the colors of the rainbow can be obtained from just one material, as shown for CdSe in ▶ Figure 12.44.

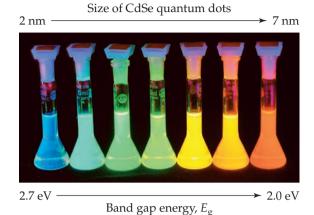

Give It Some Thought

Large crystals of ZnS can show photoluminescence, emitting ultraviolet photons with energies equal to the band gap energy and a wavelength of 340 nm. Is it possible to shift the luminescence so that the emitted photons are in the visible region of the spectrum by making appropriately sized nanocrystals?

GO FIGURE

As the size of the quantum dots decreases, does the wavelength of the emitted light increase or decrease?

▲ Figure 12.44 Photoluminescence depends on particle size at the nanoscale. When illuminated with ultraviolet light, these solutions, each containing nanoparticles of the semiconductor CdSe, emit light that corresponds to their respective band gap energies. The wavelength of the light emitted depends on the size of the CdSe nanoparticles.

Quantum dots are being explored for applications ranging from electronics to lasers to medical imaging because they are very bright, very stable, and small enough to be taken up by living cells even after being coated with a biocompatible surface layer.

Semiconductors do not have to be shrunk to the nanoscale in all three dimensions to show new properties. They can be laid down in relatively large two-dimensional areas on a substrate but be only a few nanometers thick to make quantum wells. Quantum wires, in which the semiconductor wire diameter is only a few nanometers but its length is very long, have also been made by various chemical routes. In both quantum wells and quantum wires, measurements along the nanoscale dimension(s) show quantum behavior, but in the long dimension, the properties seem to be just like those of the bulk material.

Metals on the Nanoscale

Metals also have unusual properties on the 1-100-nm-length scale. Fundamentally, this is because the mean free path (Section 10.8) of an electron in a metal at room temperature is typically about 1-100 nm. So when the particle size of a metal is 100 nm or less, one might expect unusual effects because the "sea of electrons" encounter a "shore" (the surface of the particle).

Although it was not fully understood, people have known for hundreds of years that metals are different when they are very finely divided. Dating back to the middle ages, the makers of stained-glass windows knew that gold dispersed in molten glass made the glass a beautiful deep red (Figure 12.45). Much later, in 1857, Michael Faraday reported that dispersions of small gold particles could be made stable and were deeply colored some of the original colloidal solutions that he made are still in the Royal Institution of Great Britain's Faraday Museum in London (Figure 12.46).

▲ Figure 12.45 Stained glass window from the Chartres Cathedral in France. Gold nanoparticles are responsible for the red color in this window, which dates back to the twelfth century.

▲ Figure 12.46 The solutions of colloidal gold nanoparticles made by Michael Faraday in the 1850s. These are on display in the Faraday Museum, London.

A GO FIGURE

How many bonds does each carbon atom in C_{60} make? Based on this observation would you expect the bonding in C_{60} to be more like that in diamond or that in graphite?

▲ Figure 12.47 Buckminsterfullerene, C₆₀. The molecule has a highly symmetric structure in which the 60 carbon atoms sit at the vertices of a truncated icosahedron. The bottom view shows only the bonds between carbon atoms.

Other physical and chemical properties of metallic nanoparticles are also different from the properties of the bulk materials. Gold particles less than 20 nm in diameter melt at a far lower temperature than bulk gold, for instance, and when the particles are between 2 and 3 nm in diameter, gold is no longer a "noble," unreactive metal; in this size range it becomes chemically reactive.

At nanoscale dimensions, silver has properties analogous to those of gold in its beautiful colors, although it is more reactive than gold. Currently, there is great interest in research laboratories around the world in taking advantage of the unusual optical properties of metal nanoparticles for applications in biomedical imaging and chemical detection.

Carbon on the Nanoscale

We have seen that elemental carbon is quite versatile. In its bulk sp^3 -hybridized solid-state form, it is diamond; in its bulk sp^2 -hybridized solid-state form, it is graphite. Over the past three decades, scientists have discovered that sp^2 -hybridized carbon can also form discrete molecules, one-dimensional nanoscale tubes, and two-dimensional nanoscale sheets. Each of these forms of carbon shows very interesting properties.

Until the mid-1980s, pure solid carbon was thought to exist in only two forms: the covalent-network solids diamond and graphite. In 1985, however, a group of researchers led by Richard Smalley and Robert Curl of Rice University and Harry Kroto of the University of Sussex, England, vaporized a sample of graphite with an intense pulse of laser light and used a stream of helium gas to carry the vaporized carbon into a mass spectrometer. ∞ (Section 2.4, "The Mass Spectrometer") The mass spectrum showed peaks corresponding to clusters of carbon atoms, with a particularly strong peak corresponding to molecules composed of 60 carbon atoms, C_{60} .

Because C_{60} clusters were so preferentially formed, the group proposed a radically different form of carbon, namely, nearly spherical C_{60} molecules. They proposed that the carbon atoms of C_{60} form a "ball" with 32 faces, 12 of them pentagons and 20 hexagons (\P Figure 12.47), exactly like a soccer ball. The shape of this molecule is reminiscent of the geodesic dome invented by the U.S. engineer and philosopher R. Buckminster Fuller, so C_{60} was whimsically named "buckminsterfullerene," or "buckyball" for short. Since the discovery of C_{60} , other related molecules made of pure carbon have been discovered. These molecules are now known as fullerenes.
